PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

2313 THE INFLUENCE OF 400 R X-IRRADIATION ON THE NUMBER AND THE LOCALIZATION OF MATURE AND IMMATURE GOBLET CELLS AND PANETH CELLS IN INTESTINAL CRYPT AND VILLUS. (Eng.) Van Dongen, J. M.; Kooyman, J.; Visser, W. J. (Dept. Cell Biology and Genetics, Erasmus Univ., P.O. Box 1738, Rotterdam, Netherlands). *Cell Tissue Kinet.* 9(1): 65-75; 1976.

The influence of 400 R x-irradiation on the localization and number of mature and immature goblet cells and Paneth cells in Wistar rat duodenal epithelium was studied. At short times after irradiation when the total proliferative activity in the crypts of Lieberkuhn was reduced, the proportion of mature and immature goblet cells was increased; an absolute increase in the number of goblet cells in the crypts was also found. The immature goblet cells were localized in the lower half of the crypt as in control animals, whereas the number of the mature cells increased over the whole crypt length. When the proliferative activity of the crypt cells increased again from 12-48 hr after irradiation, the number of both types of goblet cells decreased. Between 48 and 72 hr, when the whole crypt was involved in proliferation, a second increase of both types of goblet cells was found. However, the localization of the immature goblet cells was no longer restricted to the lower half of the crypt; they also appeared at the higher cell positions. No immature goblet cells were found on the villus, and the changes in the number of mature goblet cells reflected the changes induced by irradiation in the goblet cell population in the crypt. The absolute number and localization of Paneth cells did not change under the experimental conditions.

2314 MORPHOLOGICAL CORRELATES OF FUNCTIONAL ENHANCEMENT OF LIVER MITOCHONDRIA NOURISHED WITH EXCESS PORTAL BLOOD. (Eng.) Takasan, H.; Mizukami, T.; Yamada, T.; Ozawa, K.; Honjo, I. (Kyoto Univ. Sch. Medicine, Shogoin, Kawaramachi, Sakyo-ku, Kyoto, Japan). *Nihon Rynsho Denshi Kenbikyo Gakkai-Shi* 24(4):235-245; 1975.

The changes of hepatic ultrastructure and mitochondrial metabolism induced by excess portal blood supply were studied in rabbits that were subjected to the ligation of a branch of portal vein. In parallel with an enhancement of phosphorylative capacity, mitochondria increased in size and number in the liver lobes nourished with excess portal blood as compared with sham-operated controls. Swollen, rounded, and electron-lucent mitochondria and mitochondrial partitions, clearly associated with inner membrane, were most numerous at 24 hr after portal ligation, and mitochondrial respiratory and phosphorylative capacities were also maximally enhanced at this time. At about 48 hr, when an increase of nuclear DNA synthesis occurred, the number and size of mitochondria returned to the control levels in parallel with decreasing phosphorylative capacity. It is suggested that there is a relation between the degree of enhanced phosphorylative capacity and the increased mitochondrial number and size. It is likely that increases in mitochondrial number and their sizes represent a response to increased energy demands and are caused by the division of mitochondria.

2315 ANALYTICAL SUBCELLULAR FRACTIONATION STUDIES ON RAT LIVER AND ON ISOLATED JEJUNAL ENTEROCYTES WITH SPECIAL REFERENCE TO THE SEPARATION OF LYSOSOMES, PEROXISOMES, AND MITOCHONDRIA. (Eng.) Peters, T. J.; Shio, H. (Royal Postgraduate Medical Sch., Du Cane Road, London W12 OHS, England). *Clin. Sci. Mol. Med.* 50(5): 355-366; 1976.

A method for isolating rat jejunal enterocytes that are relatively uncontaminated by other components is described in Sprague-Dawley rats. In addition, the properties of the subcellular organelles from these enterocytes are compared with those of rat liver. The Reiser-Christiansen technique was modified in that cell dissociation occurred at 25 C, rather than 33 C, and the cells were washed and centrifuged in 0.3 M sucrose containing 1 mM EDTA and 22 mM ethanol. Electron microscopy indicated the preservation of lysosomal integrity. α-Glucosidase, alkaline phosphatase, and leucyl-β-naphthylamidase were considerably more active in the enterocyte than in the liver. Catalase and D-amino acid oxidase activities were considerably higher in liver than in the enterocyte (catalase was 100 times more active in liver than in enterocyte). Cytochrome c oxidase had a higher specific activity in the enterocyte, but malate and lactate dehydrogenases and monamine oxidase were 2 to 3 times more active in the liver. Nine acid hydrolases had different relative activities in the two tissues. Substrate specificities of D-amino acid oxidase from the two tissues were similar, as was the activity of latent N-acetyl-β-glucosaminidase. Attempts to separate the enterocyte subcellular organelles, characterized by their marker enzymes, with isopycnic centrifugation were unsuccessful, but good separation was achieved by sedimentation through a shallow sucrose density gradient with a superimposed inverse gradient of low-molecular-weight dextran. The properties and enzyme activities of the principal subcellular organelles in rat liver cells and enterocytes are compared.

2316 CELL PROLIFERATION KINETICS IN NORMAL HUMAN GASTRIC MUCOSA: STUDIES ON DIURNAL FLUCTUATIONS AND EFFECT OF FOOD INGESTION. (Eng.) Hansen, O. H.; Pedersen, T.; Larsen, J. K. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Gastroenterology* 70(6):1051-1054; 1976.

Ninety-six biopsy specimens of gastric mucosa from three healthy subjects were studied to: (a) estimate the fasting labeling index in the fundic and antral mucosa after *in vitro* incorporation of ^{3}H-thymidine; (b) investigate whether the mucosal cell proliferation kinetics are subject to diurnal variations; and (c) determine the effect of food ingestion on the rate of mucosal cell proliferation. After incubation with ^{3}H-thymidine (20 μCi/ml), autoradiographs were prepared by the dipping technique, and the labeling and mitotic indices in the fundic and antral mucosa were estimated. The number of DNA-synthesizing cells and the mitotic frequencies were higher in antral mucosa compared to mucosa in the fundic stomach ($p<0.01$). Biopsies were taken after 12 hr of fasting and at various intervals during the following day. No diurnal variations in the labeling and mitotic indices were observed. Biopsies were taken at various intervals after ingestion of a protein-rich meal, preceded by 12 hr of fasting. Significant changes in cell proliferation were not found either in antral or in fundic mucosa, indicating that a meal does not affect the rate of cell renewal in human gastric mucosa.

2317 THE DEVELOPMENT OF MICROPEROXISOMES IN THE CELLS OF THE PROXIMAL TUBULES OF THE KIDNEY AND EPITHELIUM OF THE SMALL INTESTINE DURING THE EMBRYONIC DEVELOPMENT AND POSTNATAL PERIOD. (Eng.) Pipan, N.; Psenicnik, M. (Inst. Human Biology, Ljubljana, Yugoslavia, Lipiceva 2). *Histochemistry* 44(1):13-21; 1975.

2318 DEVELOPMENT OF THE SMALL INTESTINE IN THE HYPOPHYSECTOMIZED RAT. I. GROWTH, HISTOLOGY, AND ACTIVITY OF ALKALINE PHOSPHATASE, MALTASE, AND SUCRASE. (Eng.) Yek, K.-Y.; Moog, F. (Dept. Biology, Washington Univ., St. Louis, MO 63130). *Dev. Biol.* 47(1):156-172; 1975.

2319 EFFECT OF DENERVATION ON THE MITOTIC INDEX OF THE INTESTINAL EPITHELIUM OF THE RAT. (Eng.) Musso, F.; Lachat, J.-J.; Cruz, A. R.; Goncalves, R. P. (Universidade Federal do Espirito Santo, Brazil). *Cell Tissue Res.* 163(3):395-402; 1975.

2320 MORPHOLOGICAL STUDIES ON THE SYNTHESIS OF SECRETORY GRANULES IN CONVOLUTED TUBULES OF MOUSE SUBMANDIBULAR GLAND. (Eng.) Kaiho, M.; Nakamura, T.; Kumegawa, M. (Sch. Medicine, Yokohama City Univ., Urafunecko, Yokohama, Japan). *Anat. Rec.* 183(3):405-420; 1975.

2321 CHANGES IN NUMBERS OF ACIDOPHILIC AND BASOPHILIC CONNECTIVE TISSUE GRANULATED CELLS IN THE INTESTINE OF THE RAT DURING THE ESTROUS CYCLE. (Eng.) Johnson, S. M.; Nellor, J. E. (Coll. Osteopathic Medicine, Michigan State Univ., East Lansing, MI 48824). *Anat. Rec.* 183(3):449-458; 1975.

2322 HISTOPATHOLOGICAL EFFECT OF Clostridium perfringens ENTEROTOXIN IN THE RABBIT ILEUM. (Eng.) McDonel, J. L.; Duncan, C. L. (Food Res. Inst. and Dept. Bacteriology, Univ. Wisconsin, Madison, WI 53706). *Infect. Immun.* 12(5):1214-1218; 1975.

ABSORPTION - EXCRETION - TRANSPORT

2323 THE INFLUENCE OF VILLOUS COUNTER CURRENT EXCHANGE ON INTESTINAL ABSORPTION. (Eng.) Winne, D. (Pharmakologisches Institut der Universitat, Wilhelmstrasse 56, D-7400 Tubingen, Federal Republic of Germany). *J. Theor. Biol.* 53(1):145-176; 1975.

Equations are derived that describe the influence of a counter current exchange (CCE) in the intestinal villi on intestinal absorption and elimination. CCE retards absorption or elimination, diminishes the rate of absorption or elimination, and builds up a gradient from tip to base during absorption or base to tip during elimination. A decreased villous blood flow, particularly with decreasing linear flow rate, increases the efficiency of CCE, as does increased permeability of the substances. Experimental data in the literature, from studies of the cat, conform to the theoretical predictions, while those from studies of the rabbit and rat small intestine do not demonstrate evidence for CCE. These differences may be due to differing vascular anatomy of the villi of the three species. The vasculature in the cat consists of one arterial limb and several venous limbs connected in a hairpin-like manner. The distance between the arterial and venous limbs (length approximately 1 mm) is 10-20 μm, thus fulfilling the requirements for an extravascular shunt and CCE. The rat villus is leaf-like and the vasculature is frequently trapezoidal. The rabbit villus has a leaf- or tongue-like shape, and the vasculature has a triangular contour.

2324 INTERACTION BETWEEN SUGARS AND AMINO ACIDS IN INTESTINAL ABSORPTION BY RAT, IN VIVO. (Eng.) Bolufer, J.; Larralde, J.; Ponz, F. (Dept. Animal Physiology, Univ. Navarra, Pamplona, Spain). *Experientia* 31(10):1171-1173; 1975.

Mutual interactions among glucose, galactose, and

eucine absorption by the rat small intestine were
tudied *in vivo*. Sugar and amino acid solutions
ere circulated through segments of intestine of
istar rats, and D-[1-^{14}C]galactose, D-[1-^{14}C]glu-
ose, and L-[1-^{14}C]leucine readings were taken in
liquid scintillation counter. When 20 mM leucine
as present, an inhibition of 33% for glucose and
f 28% for galactose absorption were observed. On
losed circuit perfusion with a peristaltic pump,
) mM galactose inhibited the absorption of leucine
t initial concentrations of 20, 4, and 1 mM by 17%,
3%, and 25%, resp. These experiments confirm the
utual interaction between galactose and leucine
n vivo.

325 SOME ASPECTS OF THE INTESTINAL ABSORPTION OF ZINC IN MAN.

(Eng.) Andersson, K. E.;
ratt, L.; Dencker, H.; Lanner, E. (University
osp., S-221 85 Lund, Sweden). *Eur. J. Clin.
harmacol.* 9(5/6):423-428; 1976.

he intestinal absorption of zinc was investigated
y determining the serum zinc concentrations in
eripheral venous blood in eight healthy volunteers
t various times after p.o. administration of 50 mg
n^{++}. The same dose was given to six patients who
ere treated for obesity by jejuno-ileostomy. In
he healthy volunteers, the mean serum zinc concen-
ration was 0.98 μg/ml pre-administration, and a mean
eak concentration of 2.39 μg/ml was found after 3
r. In the patients, the mean serum zinc concentra-
ion was 0.67 μg/ml pre-administration, and a mean
eak concentration of 1.31 μg/ml was found after 90
in. Zinc^{++} (50 mg) was also given to three patients
ho underwent transumbilical catheterization of the
ortal vein for diagnostic purposes; serum zinc con-
concentrations were measured in portal and peripheral
enous blood that were sampled simultaneously. No
ignificant differences were found between the
concentration of zinc in portal and peripheral venous
lood during absorption, suggesting slow passage of
zinc across the intestinal wall. The mechanisms in-
volved in the gastrointestinal absorption of zinc
are still unknown, and active transport has not been
determined.

2326 INTESTINAL CALCIUM ABSORPTION: DIFFERENCES IN TRANSPORT BETWEEN DUODENUM AND ILEUM.

(Eng.) Behar, J.; Kerstein, M. D. (Veterans Admin. Hosp., West Haven, CT 06516). *Am. J. Physiol.* 230(5):1255-1260; 1976.

The *in vivo* interaction of calcium transport with sugar, sodium, and water absorption was studied in intestinal loops of Charles River strain rats fed laboratory chow and in those of vitamin D-deficient and -repleted rats. The vitamin D-deficient animals were fed a vitamin D-free rachitogenic diet for at least 12 weeks before the experiments were performed; then half of these animals were then repleted with 50,000 U of vitamin D$_2$ by i.m. injection 48 and 24 hr before the experiments. Calcium absorption in the duodenum was enhanced by 25 mM D-glucose only in the vitamin D-deficient rats. In both vitamin D-deficient and -repleted ileum, calcium absorption decreased when NaCl was replaced by mannitol; however, it remained unchanged when NaCl was replaced by choline chloride or urea. Calcium absorption was enhanced by actively transported sugars and by increasing net water flow generated by differences in osmotic pressure and urea. Under all experimental conditions there was a strong association between net water and calcium absorption in the ileum. These findings suggest that calcium absorption is enhanced by solvent drag, although the role of sodium cannot be excluded completely.

2327 INTESTINAL CaBP: A NEW QUANTITATIVE INDEX OF VITAMIN D DEFICIENCY IN THE RAT.

(Eng.) Bronner, F.; Freund, T. (Univ. Connecticut Health Center, Farmington, CT 06032). *Am. J. Physiol.* 229(3):689-694; 1975.

The effects of 25-hydroxycalciferol (25-OH-D$_3$) on the plasma calcium level and intestinal calcium-binding protein (CaBP) concentration levels were studied in vitamin D-deficient male Sprague-Dawley rats. The time course of the calcemic response to a single i.p. injection of 25-OH-D$_3$ (15 U) indicated a peak at 24-25 hr. The extent of the calcemic response was dose-related and was a linear function of the dose raised to the power of 2 over the range of 1.5-150 U. The dose response curve for intestinal CaBP was also linearly related to dose over the same range and was a function of dose raised to the power of 2. Dihydrotachysterol was as effective as 25-OH-D$_3$. When vitamin D-deficient rats were fed a high calcium, high phosphorous diet, hypocalcemia was not present, but the intestinal level of CaBP was nil, suggesting that CaBP can be a more reliable index of the vitamin D status of the animal than its plasma calcium level, provided that calcium intake is controlled.

2328 IN VITRO UPTAKE AND METABOLISM OF PTEROYLPOLYGLUTAMATE BY RAT SMALL INTESTINE.

(Eng.) Halsted, C. H.; Reisenauer, A.; Back, C.; Gotterer, G. S. (Dept. Internal Medicine, Univ. California, Davis, CA 95616). *J. Nutr.* 106(4): 485-492; 1976.

The digestion and cellular uptake of ^{14}C-pteroylheptaglutamate (^{14}C-PG-7) was studied using an isolated cell preparation from small intestine Wistar rat and by assay of folate conjugase in whole homogenates and brush border fractions of rat small intestinal mucosa. In the cell preparation, ^{14}C-pteroylmonoglutamate (^{14}C-PG-1), the principal degradation product of ^{14}C-PG-7, was concentrated earlier in the cell fraction than in the extracellular fraction, while the concentrations equalized after 15 min. Incubation of cells with equimolar ^{14}C-PG-7 and ^{3}H-PG-1 was followed by a threefold greater cellular concentration of ^{14}C-PG-1 than ^{3}H-PG-1. In subcellular fractionation studies, folate conjugase was minimally present in the brush border relative to the supernatant fraction. These data suggest that ^{14}C-PG-7 is transported into the epithelial cell of the intestinal mucosa prior to its hydrolysis by intracellular folate conjugase.

2329 THE EFFECT OF ALDOSTERONE AND THE RENIN-ANGIOTENSIN SYSTEM OF SODIUM, POTASSIUM AND CHLORIDE TRANSPORT BY PROXIMAL AND DISTAL RAT COLON IN VIVO. (Eng.) Dolman, D.; Edmonds, C. J. (Clinical Research Centre, Watford Road, Harrow, Middlesex, HA1 3UJ, England). *J. Physiol.* 250(3): 597-611; 1975.

The roles of aldosterone and angiotensin in the direct control of epithelial sodium transport *in vivo* were investigated by measuring electrical potential differences (p.d.) and the fluxes of sodium, potassium, and chloride in Wistar rat colon. Exogenous angiotensin (0.5, 50, or 500 ng/min/kg) and aldosterone (500 ng/min/kg) were administered by both short- and long-term infusions, and endogenous secretion of the hormones was varied by dietary sodium and by nephrectomy and/or adrenalectomy. Angiotensin had no significant action on p.d. or on the ionic fluxes of the proximal or distal colon. The increase in p.d. produced by infusing aldosterone was unaffected by giving angiotensin concurrently. The effect of sodium depletion in stimulating sodium absorption and potassium secretion was completely abolished by adrenalectomy but it was unaffected by nephrectomy. During prolonged infusion of angiotensin into adrenalectomized rats, a small fall in fecal fluid and sodium content was observed, but this change had little significance in sodium homeostasis. Aldosterone and sodium depletion stimulated sodium absorption in both proximal and distal colon, but significant increase in potassium secretion was demonstrable only in the distal colon. Bicarbonate secretion (by calculation) was unaffected. In the proximal colon, the increased sodium absorption was accompanied by increased chloride absorption, while in the distal colon, the sodium-potassium exchange was increased. Adrenalectomy reduced potassium secretion in both proximal and distal colon, but sodium absorption was only significantly reduced in the proximal colon. It is concluded that angiotensin in the living animal does not play a role as an important salt retaining hormone by direct epithelial action. Aldosterone has a considerable effect, which is independent of the presence of angiotensin, and which differs in proximal and distal colon in relation to the relative effects on chloride absorption and potassium secretion.

2330 EFFECT OF ASPIRIN ON NORMAL AND CHOLERA TOXIN-STIMULATED INTESTINAL ELECTROLYTE TRANSPORT. (Eng.) Farris, R. K.; Tapper, E. J.; Powell, D. W.; Morris, S. M. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514). *J. Clin. Invest.* 57(4):916-924; 1976.

The effect of aspirin on normal and cholera toxin-stimulated electrolyte transport was investigated *in vitro*. In the Ussing chamber, 10 mM aspirin decreased control rabbit ileal potential difference and short-circuit current by 50% and increased conductance by 28%. Bidirectional electrolyte flux determinations indicated that aspirin significantly increased both Na and Cl absorption and reduced the residual flux (which probably represents HCO_3 secretion) to zero. α-Adrenergic blockers did not prevent the electrical effects of aspirin, suggesting that aspirin does not exert its effect through releas of tissue stores of catecholamines. In the presence of aspirin, cholera toxin increased the potential difference and short-circuit current, and decreased the conductance of rabbit ileum (qualitatively similar to control tissues). However, aspirin reversed cholera toxin-stimulated Na transport from secretion to absorption, inhibited cholera toxin, induced Cl secretion by 58%, and partially, but not significantly, inhibited HCO_3 secretion. Thus, the inhibitory effect of aspirin on cholera toxin-induced electrolyte secretion appears to be due to aspirin-stimulated Na and Cl absorption. Although aspirin reduced tissue cyclic AMP concentrations in normal and cholera toxin-stimulated ileum, it also inhibited the electrolyte secretion induced by exogenous cyclic AMP. Thus, if aspirin's stimulatory effect on sodium and anion absorption in normal tissue and its inhibitory effect on cholera toxin-stimulated sodium and anion secretion involves a cyclic AMP-mediated system the effect must be at a step distal to cyclic AMP production or degradation.

2331 THE EFFECT OF SECRETIN ON HYDROGEN ION TRANSPORT IN THE DUODENUM AND JEJUNUM. (Eng.) Chung, R. S.; Johnson, G. M.; Denbesten, L. (Veterans Admin. Hosp., Iowa City, IA 52242). *J. Surg. Res.* 20(5):467-471; 1976.

The capacity of the upper small intestine to dispose of acid in the absence of bile and pancreatic juice was measured in a group of five cats. *In vivo* titrations were performed in cat upper duodenum, lower duodenum, and jejunum to various pH levels in a reci culating perfusion circuit. The effect of secretin in this capacity to dispose of acid was investigated by repeating the experiment with i.v. infusion of GI secretin at 3 Clinical U/kg/hr. Identical results were obtained in the lower duodenum and jejunum, but a significant increase in rate of H^+ removal occurred in the upper duodenum at all pH levels (2.0-6.0). Histological examination showed that the Brunner's glands did not extend for more than half the length of upper duodenum, and were not found in either the lower duodenum or jejunum. No morphological changes, other than depletion of mucin in Brunner's glands, were detected in animals that were stimulated with secretin. It is concluded that secretin's only effect on H^+ transport in the upper small intestine is to increase alkaline secretion from Brunner's glands, for example, resulting in a larger amount of neutralization.

2332 NUTRITIONAL CONSEQUENCES OF THE MAILLARD REACTION. THE ABSORPTION OF FRUCTOSE-L-TRYPTOPHAN IN THE LARGE INTESTINE OF THE RAT. (Eng. Tanaka, M.; Lee, T.-C.; Chichester, C. O. (Dept. Food and Resource Chemistry, Univ. Rhode Island, Kingston, RI 02881). *J. Nutr.* 105(8):989-994; 1975.

2348 THE VAGAL CONTROL OF THE ILEO-CECAL SPHINCTER IN THE CAT. (Eng.) Pahlin, P. E.; Kewenter, J. (Sahlgrenska Sjukhuset, Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 96(4): 433-442; 1976.

The effect of efferent cervical vagal stimulation on a flow through the ileo-cecal sphincter (ICS) was studied in 53 cats which were anesthetized with chloralose. The motor activity of the jejunum, ileum, and large intestine adjacent to the sphincter were recorded simultaneously. Vagal stimulation caused a decrease in the transsphincteric flow and increased motor activity in the ileum. Increased motor activity in the proximal colon was recorded only occasionally. When the vagal nerves were stimulated during continuous splanchnic stimulation, the transsphincteric flow was decreased although the tone and motility of the ileum were suppressed. Guanethidine (1-3 mg/kg) blocked or suppressed the effect of vagal stimulation on the transsphincteric flow, while the excitatory response of the proximal colon was greatly enhanced. This indicates that the reduction of the transsphincteric flow following vagal stimulation was at least partly due to a direct effect of the vagal nerves on the sphincteric muscle and not to a squeezing effect of that part of the colonic wall that surrounds the sphincter. Atropine (0.1 and 1 mg/kg) blocked all responses to vagal stimulation. Thus, both guanethidine and atropine blocked the vagally induced contraction of the ICS. Relaxation of the ICS was never obtained by vagal stimulation, even when the tone of the sphincter was increased by infusion of noradrenaline.

2349 HISTAMINE RECEPTORS IN ESOPHAGEAL SMOOTH MUSCLE OF THE OPOSSUM. (Eng.) DeCarle, D. J.; Brody, M. J.; Christensen, J. (Univ. Hosps. Iowa City, IA 52242). *Gastroenterology* 70(6):1071-1075; 1976.

Esophageal smooth muscle of the opossum was examined for histamine H_1 and H_2 receptors. The effects of histamine, 4-methylhistamine (4-MH), and 2-(2-pyridyl) ethylamine (PEA), mepyramine and metiamide, and the histamine-releasing substance compound 48/80 on lower esophageal sphincter (LES) and esophageal body (EB) smooth muscle were studied in a superfused tissue bath. Histamine, PEA (an H_1 receptor agonist), and compound 48/80 caused a dose-related increase in LES basal tension and in EB off response amplitude, the threshold for histamine being 6.7×10^{-8} M and for PEA being 6.7×10^{-7} M. In the presence of mepyramine (an H_1 receptor antagonist), the effects of histamine and compound 48/80 were reversed to inhibition of both LES basal tension and EB off response amplitude, while the effect of PEA was abolished. Metiamide (an H_2 receptor antagonist) did not alter responses to histamine, PEA, or compound 48/80. 4-Methylhistamine (an H_2 receptor agonist) caused a reduction in LES tension and EB off response amplitude, but it caused an increase in those parameters in the presence of metiamide. A combination of mepyramine and metiamide abolished responses to all agonist drugs. The results indicate that LES and EB smooth muscle contain both excitatory H_1 and inhibitory H_2 receptors for histamine. Endogenous histamine released from storage sites in LES and EB and exogenous histamine both preferentially activate H_1 receptors.

2350 GALLBLADDER PRESSURE-VOLUME RESPONSE TO GASTROINTESTINAL HORMONES. (Eng.) Ryan, J.; Cohen, S. (Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Am. J. Physiol.* 230(6):1461-1465; 1976.

The pressure-volume (PV) response of the opossum gallbladder was studied under basal conditions and after the continuous i.v. infusion of gastrin I, secretin, and cholecystokinin (CCK). The hormone effects were examined individually and in combination. The unstimulated gallbladder was capable of accommodating increases in intraluminal volume with only slight changes in intraluminal pressure. CCK (0.025, 0.25, and 2.5 μg/kg/hr) significantly increased the pressure recorded from the gallbladder ($p<0.01$). The pressure depended upon the concentration of CCK and the intraluminal volume. Gastrin I (0.25 and 0.50 μg/kg/hr) had no independent effect on the PV response of the gallbladder but it reduced the stimulatory effect of CCK. Secretin (0.25 U/kg/hr) alone decreased the PV response of the gallbladder. Secretin also antagonized the stimulatory response to CCK. These findings suggest that the regulation of gallbladder motor function and pressure generation, exclusive of neural input, may depend upon the interaction of CCK with gastrin and secretin and the intraluminal volume of the organ at the time of stimulation.

2351 INTESTINAL MYOELECTRIC ACTIVITY IN RESPONSE TO LIVE *Vibrio cholerae* AND CHOLERA ENTEROTOXIN. (Eng.) Mathias, J. R.; Carlson, G. M.; DiMarino, A. J.; Bertiger, G.; Morton, H. E.; Cohen, S. (Veterans Admin. Hosp., Gainesville, FL). *J. Clin. Invest.* 58(1):91-96; 1976.

The myoelectric response in the ileum of New Zealand white rabbits was studied in response to live *Vibrio cholerae* culture, a whole cell lysate of cholera, and to the purified enterotoxin. Each cholera preparation produced a series of highly organized migrating action potential complexes (MAPC). An MAPC was defined as action potential discharge with a duration of 2.5 sec or longer, followed by similar activity on at least one other consecutive electrode site. The mean and modal onset time of MAPC activity occurred 4 hr after the infection with live *Vibrio cholerae* culture, the freeze-dried whole cell lysate preparation, or the purified enterotoxin. After the onset of activity this pattern persisted for the duration of the recording period (up to 12 hr). The MAPC had a mean propagation velocity of 0.85 cm/sec, which remained constant with time. Direct visual observation of the loop revealed that the MAPC's resulted in contractions that propelled intraluminal contents in an aborad direction. The mean fluid output from the 12-cm ileal loops was 6.4 ml/hr. Control experiments consisted of recordings from: a ligated ileal loop into which nothing was placed; a ligated ileal loop into which either uninfected culture broth or 0.9% NaCl solution was injected; a ligated ileal loop infused with 0.9% NaCl solution at a rate of 11.2 ml/hr; and rapid injection of 1.0, 2.5, 5.0, or 10.0-ml boluses of 0.9% NaCl into the proximal catheter. MAPC activity was not observed in any of the control experiments. These studies indicate that in addition to a secretory component to cholera, there exists a highly organized MAPC that results in contractions that propel intraluminal contents in an aborad direction.

2352 EFFECTS OF 5-HYDROXYTRYPTAMINE AND MORPHINE ON THE STOMACH MOTILITY IN SITU. (Eng.) Terawaki, Y.; Takayanagi, I.; Takagi, K. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan). *Jpn. J. Pharmacol.* 26(1):7-12; 1976.

The effect of 5-hydroxytryptamine and morphine on the stomach movement of both unanesthetized and anesthetized animals (female cats, male rabbits, and male guinea pigs) was investigated *in situ*. In unanesthetized rabbits, 5-hydroxytryptamine (200 µg/kg) caused an initial rapid contraction, while morphine (200 µg/kg) caused depression of spontaneous movement, which was not modified by phentolamine (5 mg/kg) and propranolol (2 mg/kg). Pretreatment with phentolamine (5 mg/kg) and propranolol (2 mg/kg) completely reversed the inhibition of movement produced by adrenalin (10 µg/kg) but only partially reversed the inhibition by 5-hydroxytryptamine (200 µg/kg). In anesthetized rabbits, after the abolition of movement due to pentobarbital (30 mg/kg), 5-hydroxytryptamine (200 mg/kg) induced contraction, followed by inhibition of movement. Morphine (200 µg/kg) had no effect. In unanesthetized guinea pigs, 5-hydroxytryptamine (100 µg/kg) produced a large contraction in amplitude. Pretreatment with atropine (1 mg/kg) depressed contractions produced by both 5-hydroxytryptamine (100 µg/kg) and by acetylcholine (200 µg/kg). In anesthetized guinea pigs, pentobarbital (20 mg/kg) enhanced stomach motility, followed by a gradual inhibition. 5-Hydroxytryptamine (100 µg/kg) produced contraction, while no effect was seen with morphine (100 µg/kg). Atropine (1 mg/kg) inhibited both responses to acetylcholine (200 µg/kg) and to 5-hydroxytryptamine (100 µg/kg). In unanesthetized cats, 5-hyroxytryptamine (200 µg/kg) and morphine (200 µg/kg) inhibited stomach motility. In anesthetized cats, pentobarbital (30 mg/kg) depressed spontaneous motility, while 5-hydroxytryptamine and morphine (200 µg/kg) produced slight contractions. It is concluded that the differences in the modes of action of 5-hydroxytryptamine and morphine on gastric motility are related to differences in both species and experimental conditions, i.e. anesthesia.

SECRETION AND METABOLISM

2363 CHARACTERISTICS OF INTESTINAL PHASE OF GASTRIC SECRETION. (Eng.) Konturek, S. J.; Kaess, H.; Kwiecien, N.; Radecki, T.; Dorner, M.; Teckentrupp, U. (Inst. Physiology, Medical Academy, Krakow, Poland). *Am. J. Physiol.* 230(2):335-340; 1976.

The magnitude of gastric secretion and gastrin release in the intestinal phase, and the effect of the changes of pH of meal on this phase were examined in four dogs, which were provided with special gastroduodenal fistulas, allowing for the complete separation of stomach and duodenum without interrupting the vagal connections between them. In addition, the interaction of pentagastrin with the intestinal phase was studied. A liver extract (LE) meal, confined to the stomach and maintained at pH 5.0 by an intragastric titration technique, produced acid output reaching 66% of the maximal response to histamine (MRH). Perfusion of the LE meal into the duodenum resulted in acid secretion amounting to 57% of MRH. The combination of the gastric and intestinal phases caused the highest acid output, which was about 90% of MRH. Gastric and intestinal phases induced separately were accompanied by a significant elevation in serum gastrin concentrations, which reached the highest values when both phases were evoked simultaneously. Acidification of the intestinal meal resulted in pH-dependent inhibition of gastric secretion falling to the basal values at pH 1.0. These secretory changes were mimicked by exogenous secretin (graded doses doubling every 45 min from 0.5-8.0 U/hg/hr, i.v.). Serum gastrin levels remained essentially unaffected by the acidification of the intestinal meal, while exogenous secretin significantly lowered them. It is concluded that a peptone meal in the intestine is capable of evoking a potent gastric acid and pepsin stimulation by a mechanism involving the release of antral hormone in the intact stomach with undisturbed nervous connections between the stomach and duodenum.

2364 AFTER VAGOTOMY ATROPINE SUPPRESSES GASTRIN RELEASE BY FOOD. (Eng.) Debas, H. T.; Walsh, J. H.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 70(6):1082-1084; 1976.

Changes in serum gastrin in response to feeding a meal of beef liver (15 g/kg) were measured by radioimmunoassay in five gastric fistula dogs with and without administration of atropine sulfate (0.2 mg/kg, i.v.). The studies were repeated after a truncal vagotomy that abolished acid secretion in response to 2-deoxyglucose (2-DG, 100 mg/kg/hr). Before vagotomy, atropine had little effect on the gastrin response to a meal ($p<0.05$). Vagotomy caused an increase in fasting mean serum gastrin (45 ± 5 pg/ml prevagotomy and 74 ± 5 pg/ml postvagotomy). Vagotom significantly increased ($p<0.01$) the serum gastrin response to a meal. The mean rise during the first 2.5 hr after eating was 17 ± 2 pg/ml prevagotomy and 67 ± 6 pg/ml postvagotomy. After vagotomy, atropine significantly suppressed ($p<0.01$) but did not abolish the serum gastrin response to a meal. It is concluded that vagotomy enhances the serum gastrin response to feeding and that atropine counteracts this response.

SECRETION AND METABOLISM

Stomach

2374 EFFECTS OF ASPIRIN ON GASTRIC PROSTAGLANDIN E (PGE) AND ACID OUTPUT IN NORMAL SUBJECTS. (Eng.) Child, C.; Jubiz, W.; Moore, J. G. (Veterans Admin. Hosp., Salt Lake City, UT). *Gut* 17(1):54-57; 1976.

The effects of aspirin on gastric prostaglandin E (PGE) and acid secretion were studied in eight normal men after a 12- or 16-hr fast. Subjects received 3.3 g of aspirin (1.1 g/8 hr) on 5 consecutive days; the last p.o. aspirin dose was given 8 hr before the collection of gastric juice, and rectal suppositories containing 1.3 g aspirin were given every 4 hr during the 24 consecutive hr in which gastric juice was collected. After aspirin administration, a statistically significant reduction in PGE output (concentration and volume) was observed in comparison with controls. At serum salicylate concentrations of 20-30 mg/dl, which were maintained throughout the study, the circadian rhythm in PGE output was abolished; a significantly increased sensitivity ($p<0.05$) of the PGE system to inhibition by aspirin was observed at 11 PM, 12 PM, and 1 AM. The reduction in prostaglandin output suggests that aspirin inhibits prostaglandin sysnthesis, presumably by inhibiting the enzyme prostaglandin synthetase that is believed to be present in the stomach fundus.

2375 IMMEDIATE SHORT-TIME EFFECTS OF ETHACRYNIC ACID ON FROG GASTRIC MUCOSA IN CHLORIDE-FREE SOLUTIONS. (Eng.) Schwartz, M.; Holloman, T. L.; Dinno, M. A.; Carrasquer, G. (Dept. Physics, Univ. Louisville, Louisville, KY 40208). *Proc. Soc. Exp. Biol. Med.* 151(3):523-525; 1976.

The *in vitro* effect of ethacrynic acid on the K^+ pathway of the gastric mucosa in the absence of Cl^- was studied in *Rana pipiens*. Two pairs of electrodes were used, one for sending current across the mucosa and the other for measuring the transmucosal potential difference (PD). In Cl^--free preparations, the nutrient bathing solution contained, in mM,: Na^+, 101; K^+, 4; Ca^{2+}, 1; Mg^{2+}, 0.8; SO_4^{2-}, 41.3; HCO_3^-, 25; phosphate, 1; glucose, 10; and sucrose, 40. The secretory solution contained: Na^+, 100; SO_4^{2-}, 50; and sucrose, 100; the pH of this solution was maintained at 4.90. The addition of 1 mM ethacrynic acid to the nutrient solution led to a decrease in resistance, which was accompanied by a small increase in PD. Soon after, the resistance started to increase again and the PD decreased. Washing both sides of the mucosa with sulfate solutions without ethacrynic acid restored the parameters to near control values. These results strongly suggest that the dominant effect of ethacrynic acid is not on the Na^+ pathway of the nutrient membrane; however, without knowledge of the relative resistances of the frog gastric mucosa in SO_4^{2-} media, it cannot be inferred whether ethacrynic acid affects predominantly the SO_4^{2-} or the K^+ pathway.

2376 HISTAMINE METABOLISM OF THE GUINEA-PIG GASTRIC MUCOSA. (Eng.) Bergmark, J.; Granerus, G.; Henningsson, S.; Lundell, L.; Rosengren, E. (Inst. Physiology, Univ. Lund, Sweden). *J. Physiol. (London)* 257(2):419-431; 1976.

The mobilization of gastric mucosal histamine as reflected by changes in formation and content was studied in guinea pigs while fasting, and in response to food, pentagastrin, or 2-deoxy-D-glucose. Refeeding fasting guinea pigs as well as s.c. injections of pentagastrin or 2-deoxy-D-glucose (both 200 μg/kg) raised the rate of mucosal histamine formation; pentagastrin induced a fourfold rise. Some properties of the enzyme catalyzing the formation of histamine were examined. The results indicate that this enzyme is histidine decarboxylase, L-histidine carboxylyase. Imidazole-*N*-methyl transferase, which carries out methylation of the imidazole ring to yield 1-methyl-4-(β-aminoethyl)imidazole (methylhistamine), was found in high amounts in the mucosa. The enzyme did not change upon stimulation of the mucosa. In addition, the catabolism of histamine during diamine oxidase blockade was studied concomitantly by two different procedures to investigate the formation of the side-chain methylated compounds. The amount of $[^{14}C]$methylhistamine formed from added $[^{14}C]$histamine was approximately the same as that detemined by estimating the loss of $[^{14}C]$-histamine in aliquot samples of the guinea pig gastric mucosa. These results indicate that there is no *in vitro* formation of ^{14}C-*N*-methyl and *N*-dimethylhistamine. The authors conclude that histamine is formed in the guinea pig gastric mucosa through decarboxylation of histidine by the action of a specific histidine decarboxylase and that histamine mobilization is accomplished primarily by an accelerated synthesis of the amine and not, in addition, by an increased release of preformed histamine.

2377 HISTAMINE EFFECTS ON H^+ PERMEABILITY BY ISOLATED GASTRIC MUCOSA. (Eng.) Fromm, D.; Silen, M.; Robertson, R. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Gastroenterology* 70(6):1076-1081; 1976.

Steady state rates of acid secretion, measured at pH 7, and luminal acid loss, measured at pH 4, were determined by a pH stat technique. The electrical resistance of the tissues was determined by measuring the transmural electrical potential difference response to a pulse of current. The effects of histamine on mucosal permeability to acid were studied in isolated rabbit stomach. Histamine (9×10^{-5} M) decreased antral luminal acid loss, which could not be accounted for by active H^+ secretion or appearance of organic acid. Histamine also increased antral electrical resistance and decreased the unidirectional luminal to serosal flux (J^{ls}) of ^{14}C-erythritol. Histamine, theophylline (1.3×10^{-3} M), and N^6, O^2-dibutyryl adenosine 3',5'-monophosphate (1×10^{-2} M) did not significantly alter secretion by fundus in the presence of salicylate (5×10^{-3} M). However, after removal of salicylate, these agents stimulated acid secretion. Histamine decreased luminal acid loss by both antrum and fundus treated with salicylate, increased the electrical resistance of these tissues, and decreased J^{ls} erythritol of fundic mucosa. Burimamide (1×10^{-3} M) inhibited the permeability effects of histamine on antrum and fundus. The data indicate that histamine decreases spontaneous antral mucosal permeability as well as salicylate-induced increase in mucosal permeability of both antrum and fundus. The effects of burimamide suggest that the antrum contains H_2 receptor sites, which are unrelated to acid secretion and that the fundus contains H_2 receptor sites, which also govern permeability but are independent of those related to acid secretion.

2378 A STUDY OF THE VASCULAR AND ACID SECRETORY RESPONSES OF THE RAT GASTRIC MUCOSA TO HISTAMINE. (Eng.) Main, I. H. M.; Whittle, B. J. R. (Sch. Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, England). *J. Physiol.* 257(2):407-418; 1976.

The effects of histamine on gastric mucosal blood flow, in the presence and absence of gastric acid secretion, were studied in the rat. The i.v. infusion of histamine (50 μ/kg/min) increased gastric acid secretion and mucosal blood flow until steady plateau levels were reached. Increasing histamine infusion threefold caused no further rise in acid output, but it caused an additional small increase in mucosal blood flow. The i.v. infusion of (15S)-15-methyl prostaglandin E_2 methyl ester in doses of 0.2 μg/kg/min slightly increased resting mucosal blood flow. Histamine was infused i.v. (16.5-50 μg/kg/min) 1 hr later and gave a dose dependent fall in blood pressure and an increase in mucosal blood flow, but had no effect on acid output. When acid secretion was inhibited by the histamine H2-receptor antagonists burimamide (200 μg/kg/min i.v.) and metiamide (50 μg/kg/min i.v.), histamine still increased mucosal blood flow. The use of H1-receptor antagonists to inhibit the histamine induced hyperemia was made difficult by their vasodilator actions. The selective histamine H2-receptor agonist, 4-methyl histamine, had no effect on arterial blood pressure in doses (100-150 μg/kg/min i.v.), which stimulated acid secretion. The increase in mucosal blood flow, which accompanied the stimulation of acid secretion, was inhibited by metiamide (50 μg/kg/min i.v.), 4-methyl-histamine (50-100 μg/kg/min i.v.), and (15S)-15-methyl prostaglandin E2 (0.2 μg/kg/min) infusion. These results suggest that histamine H2-receptors, primarily concerned with acid secretion, and H1-receptors, concerned with vasodilation, are both present in the rat gastric mucosa.

2379 THE EFFECT OF CAERULEIN ON GASTRIC MUCOSAL BLOOD-FLOW AND GASTRIC SECRETION. (Ger.) Koch, H.; Belohlavek, D.; Demling, L. (Medizinische Universitatsklinik, 8520 Erlangen, Krankenhausstrasse 12, West Germany). *Klin. Wochenschr.* 53(9):447-448; 1975.

The effect of cerulein on the mucosal blood flow, gastric acid secretion, and pepsin secretion was investigated in 15 patients. Cerulein (0.1 μg/kg/hr) significantly inhibited the gastric mucosal blood flow ($p<0.005$) and the acid secretion ($0.05>p>0.01$), which had been stimulated by pentagastrin (1.5 μg/kg/hr). Pepsin secretion stimulated with pentagastrin also decreased, but not significantly. However, cerulein caused a slight but statistically insignificant increase in acid secretion stimulated by histamine (40 μg/kg/hr). At the same time, gastric mucosal blood flow and pepsin output decreased slightly but not significantly. The reduction of acid output when cerulein was administered together with pentagastrin is thought to be due to competitive inhibition, since the two substances have a similar chemical structure. The mucosal blood flow of the stomach, measured with the heat-clearance technique, also decreased when cerulein was administered after pentagastrin stimulation. The fact that the mucosal blood flow remains unchanged after the administration of histamine suggests that the reduction in mucosal blood flow observed with pentagastrin is a consequence, and not the cause, of the acid inhibition occurring at the same stage.

2391 MICROCANNULATION--A NEW MICROPUNCTURE TECHNIQUE APPLICATION IN CAT PANCREAS SECRETION. (Eng.) Reber, H. A.; Lightwood, R. (Univ. California Sch. Medicine, San Francisco, CA 94121). *J. Appl. Physiol.* 40(6):984-986; 1976.

A new micropuncture technique of microcannulation was developed and applied in cats to study exocrine secretion in the pancreatic ducts. Two micropipets of different diameters were assembled with the smaller pipet (10-20 μm) mounted inside the larger (25-50 μm). Using this combination, a larger pancreatic duct (<300 μm) was punctured, and the inner pipet was advanced into the lumen of a small (20-50 μm) duct, which was otherwise inaccessible. In anesthetized cats during maximal stimulation with secretin (GIH, 4-6 U/kg/hr, i.v.), the average chloride concentration of juice obtained from small ducts (25-50 μm) was 106 ± 3 mEq/l and from large ducts (50-150 μm) was 75 ± 5 mEq/l. The results were confirmed by conventional micropuncture techniques, which were technically more difficult. This new method for collecting fluid from small ducts is more physiological than direct micropuncture, and is, therefore, a useful addition to micropuncture methodology.

2397 INTRAVENOUS CHOLANGIOGRAPHY IN THE RHESUS MONKEY. PART I: DETERMINATION OF OPTIMAL IODIPAMIDE DOSE DURING A ONE HOUR INFUSION. (Eng.) Wittenberg, J.; Maturi, R. A.; Williams, L. F., Jr.; Teplick, S. K.; Preblud, S. R.; O'Brien, J. J.; Small, D. M. (Massachusetts General Hosp., Boston, MA 02114). *Invest. Radiol.* 11(1):45-53; 1976.

A 1-hr i.v. infusion cholangiography was performed in three rhesus monkeys with intact enterohepatic circulation to determine optimal iodipamide dose. Four different doses, including the standard (0.3-ml/kg) and double dose (0.6-ml/kg), as well as 0.1 ml/kg and 1.2 ml/kg levels were compared. The 0.6-ml/kg dose resulted in significantly higher biliary iodine excretion ($p<0.05$) and concentration ($p<0.05$) than the lower two doses. A 1.2-ml/kg dose caused an increase in biliary iodine concentration when compared to the 0.6-ml/kg dose, but it did not increase iodine excretion. Peak iodine excretion and concentration occurred, on the average, at 1 hr. Total bile flow was linearly related to total iodine excretion. For each 10-mg increase in excreted iodine, there was an average increase of 0.64 ml of excreted bile. The results indicate that an infusion of iodipamide is accompanied by a considerable choleretic effect, which is positively related to the dose.

2398 ANIMAL EXPERIMENTS ON THE DISTRIBUTION AND EXCRETION OF AN INTRAVENOUSLY INJECTED BILIARY CONTRAST MEDIUM (IOGLYCOMATE). (Ger.) Hilweg, V. (Evangelischen Bethesda-Krankenhauses, Heerstrasse 219, 4100 Duisberg, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 124(4):320-327; 1976.

The distribution and excretion of an i.v. injected, radioactive biliary contrast medium (Ioglycomate) were studied in dwarf pigs after the induction of choledochal, thoracic duct, and gallbladder fistulae. The investigations were carried out with free lymph and bile flow during artificial cholestasis and after occluding both ureters. Following the i.v. injection of 0.24-1.0 ml Bilivistan, there was a choleresis of up to six times the original value. The thoracic duct lymph showed only a small volume rise. The lymphatic circulation played no significant quantitative role in contrast distribution of Ioglycomate in the animal, nor did it influence the blood clearance curves. During normal bile flow, only 1.3% of the injected dose appeared in the thoracic duct within 3 hr, and during acute biliary obstru tion, only 2.6% appeared. The investigations indicat a transport maximum of 2.9 mg/min/kg for Ioglycomate, in the dwarf pig.

2399 SATURATION KINETICS OF IOPANOATE IN DOGS WITH AN INTACT ENTEROHEPATIC CIRCULATION BEFORE AND AFTER PHENOBARBITAL INDUCTION. (Eng.)

Herzog, R. J.; Nelson, J. A.; Staubus, A. E. (Univ. California Sch. Medicine, M-380, San Francisco, CA 94143). *Invest. Radiol.* 11(1):32-38; 1976.

Capacity-limited elimination of sodium iopanoate and a reproducible apparent transport maximum (Tm) were demonstrated in four nonoperated mongrel dogs. A constant infusion of iopanoate was administered i.v. at 3 different infusion rates (7.66 mg/min, 6.06 mg/min, and 5.12 mg/min) over a 3-hr period. Blood and urine samples were taken by catheterization. In all cases, the plot of blood iodine concentration against time became linear above the level of 30-40 mg of iodine/l of whole blood. The average apparent Tm/kg of iopanoate in the four dogs was 0.25 mg/min/kg. One to two months later, each dog was given 5 mg/kg/day sodium phenobarbital for 10 days, and the experiment was repeated. Phenobarbital levels in the blood of the four dogs ranged from 1.0 to 2.2 mg%. There was a linear relation between blood iodine concentration and time and blood concentration as related to the infusion rates. The apparent Tm of iopanoate after phenobarbital induction was greater than the control value of apparent Tm ($p<0.05$). It is concluded that the multiple infusion technique, developed using dogs with chronic bile fistulas is an accurate method for determining the apparent Tm of iopanoate in healthy, nonoperated dogs with normal bile salt pool.

2400 MEASUREMENT AND ALTERATION OF THE CAPACITY OF THE DISTENDED BILIARY TREE IN THE RAT. (Eng.)

Peterson, R. E.; Olson, J. R.; Fujimoto, J. M. (Univ. Wisconsin, Center for Health Sciences, Madison, WI 53706). *Toxicol. Appl. Pharmacol.* 36(2): 353-368; 1976.

A retrograde-push-back (RPB) technique was developed to estimate capacity of the biliary tree in the distended state, and this technique was applied to the rat, hamster, rabbit, and guinea pig. The technique involved establishing a relatively constant rate of [^{3}H]mannitol excretion in bile, retrogradely infusing saline into the biliary tree to clear the biliary system of mannitol, and estimating capacity as the volume of biliary fluid recollected to the point where excretion of mannitol was reestablished to half of the original rate. In male Sprague-Dawley rats, distended capacity was 37.3 ± 4.4 μl for animals with a mean liver weight of 10 g. Significant re-entry of [^{3}H]mannitol into the biliary tree occurred if the occlusion was maintained for longer periods. These facets of the method were investigated by measuring intrabiliary pressures in relation to distended capacities. Even though a linear relation existed between the liver and rat body weights, a linear relation could not be established between liver weights and distended capacities. Thus, it seems inappropriate to express distended capacities on a microliters per gram of liver basis. In another group of rats, i.v. treatment with sodium taurolithocholate (12.5 μmol/kg, i.v.) reduced the distended capacity to 25.2 ± 2.8 μl from a control value of 32.9 ± 1.0 μl. In rats treated with phenobarbital sodium (75 mg/kg, i.p., once daily) for 4 days, the increase in liver wet weight was not accompanied by an increase in distended biliary tree capacity. In the hamster (liver weight, 4.4 g) and rabbit (liver weight, 82.6 g), the distended capacities were 18.9 ± 1.8 and 849 ± 86 μl, resp. In the guinea pig, RPB with [^{3}H]mannitol produced an overshooting effect above the steady state excretion values. With [^{14}C]erythritol, this overshooting effect was not obtained, and a distended capacity estimate of 111 ± 8 μl was obtained for livers that weighed 22 g. Thus, the authors conclude that this RPB technique is useful for estimating the distended capacity of the biliary tree in the rat, hamster, and rabbit. Erythritol provides a better estimation than mannitol in the guinea pig as the bile to plasma ratio approaches 1.

2401 SIMULTANEOUS MEASUREMENT OF THE PANCREATIC AND BILIARY RESPONSE TO CCK AND SECRETIN. PRIMATE BILIARY PHYSIOLOGY XIII. (Eng.)

Gardiner, B. N.; Small, D. M. (Letterman Army Inst. Res., Presidio San Francisco, CA 94129). *Gastroenterology* 70(3):403-407; 1976.

A new model, designed to allow the simultaneous sampling of bile, pancreatic, and stomach fluid without significantly altering the normal enterohepatic circulation, is described. This system was used to monitor bile and pancreatic responses to exogenous cholecystokinin (CCK) and secretin. Tubes were surgically placed in the common bile duct and pancreatic ampulla of Rhesus monkeys to enable the separate collection of 5% of the output of each organ with the return of 95% of each fluid to the duodenum. A catheter was introduced into the stomach to prevent gastric acid from entering the duodenum. Secretin was found to increase the secretion of bile fluid (185% above control), pancreatic fluid, and HCO_3^- but to have no significant effect on pancreatic protein secretion. CCK was found to increase bile flow (70% above control), and pancreatic protein secretion (90% of control), and to mildly stimulate pancreatic and HCO_3^- secretions. High doses of CCK inhibited the activities, whereas no maximum response was found with secretin doses up to 5 U/kg. It is concluded that exogenous CCK and secretin influence bile flow at doses that produce submaximal responses from the pancreas.

2402 CIRCADIAN DISTRIBUTION OF BILE ACIDS IN THE ENTEROHEPATIC CIRCULATORY SYSTEM IN RATS. (Eng.)

Ho, K. J. (Dept. Pathology, Univ. Alabama, Birmingham, AL 35294). *Am. J. Physiol.* 230(5):1331-1335; 1976.

The possible existence of a circadian variation of bile acid distribution was studied in Sprague-Dawley rats to account for the persistent daily fluctuation of hepatic cholesterol and bile acid synthetic activity. The bile acid pool was first determined in six adult, male rats to be 12.8 mg/100 g by comparing the total radioactivity of tritiated bile acid drained through the bile fistula and the initial bile acid specific activity. The distribution of bile acids in the enterohepatic circulatory system at various times of the day was then studied in 24 additional rats; each received a single dose of tritiated taurocholate i.p. and was sacrificed 24 hr later. The nearly complete recovery of the administered radioactivity from the serum, liver, intestinal wall and content, and 24-hr feces indicated the confinement of bile acids to the enterohepatic circulation. A circadian fluctuation of the bile acid content was observed in serum, liver, and intestinal contents. The patterns of such rhythmic change varied in different segments of the intestinal tract but seemed to correlate with the time sequence of movement of bowel content and absorption of bile acids. The circadian rhythm of hepatic synthesis of bile acids, but not of cholesterol, observed by others may be, in part, directly related to the circadian fluctuation of the amount of bile acids in the liver.

2403 EFFECT OF CHOLESTEROL FEEDING ON CIRCADIAN RHYTHM OF HEPATIC AND INTESTINAL CHOLESTEROL BIOSYNTHESIS IN HAMSTERS.

(Eng.) Ho, H.-J. (Univ. Alabama in Birmingham, Medical Center, Birmingham, AL 35294). *Proc. Soc. Exp. Biol. Med.* 150(2):271-277; 1975.

Experiments were conducted to determine whether a circadian rhythm of hepatic and intestinal activity, similar to that found in rats, exists in hamsters and to evaluate the effect of cholesterol feeding on such rhythmic changes. Forty-eight adult hamsters were divided equally into two groups, which were fed a control diet and a 2% cholesterol diet, resp., under a rigid lighting (6 PM-6 AM) and feeding (6 PM-8 AM) schedule for 3 weeks. The cholesterol synthetic activity of the liver, stomach, small intestine, cecum, colon, and kidney was measured by *in vivo* conversion of acetate-1-^{14}C to cholesterol in four animals at 4-hr intervals. A remarkable circadian rhythm, with the peak at midnight and the nadir at noon, was found in the liver of the control hamsters, but it was absent in the cholesterol-fed animals, since the activity was nearly totally suppressed at all times. The small intestine exhibited a similar rhythm, with the peak at midnight, but maintained a high baseline activity from 8 AM to 6 PM. Cholesterol feeding did not alter the baseline activity but it reduced 17% of the peak activity. The other organs failed to show such a circadian rhythm. It is postulated that food, which is low in cholesterol, stimulates cholesterol synthesis in the intestinal mucosa during the process of absorption; when the absorbed food subsequently reaches the liver, it stimulates the hepatic cholesterol synthesis. The circadian rhythm observed in hepatic and intestinal cholesterol synthetic activity in hamsters is quite similar to that observed in rats.

2404 STUDIES OF HUMAN BILE: VI. INFLUENCE OF DIETS LOW IN FAT ON THE COMPOSITION OF BILE IN HEALTHY SUBJECTS.

(Eng.) Dam, H.; Prange, I.; Jensen, M. K.; Stilling, B.; Bremmelgaard, A. (Polytechnic Inst., Copenhagen, Denmark). *Z. Ernaehrungswiss.* 14(1):1-17; 1975.

The influence of dietary fat restriction for a 4- to 6-week period on the composition of duodenal bile was investigated in ten healthy women. Duodenal bile was collected furing fasting, and after injecti of cholecystokinin twice before and once at the conclusion of the diet. Total dietary fat was 11.7-19.8 g/2,000 kcal. Corresponding intakes of cholesterol and linoleic acid were 114-302 mg and 3.0-9.7 g/2,000 kcal. In 11 subjects, mean serum cholesterol declined from 5.7 to 4.76 mM after 6 weeks, and in 4 subjects, the 10-week mean cholesterol value was 4.83 mM. Mean molar ratios of total bile acid to cholesterol were 9.47 before fat restriction and 12.52 at 6 weeks, in 11 cases. In 3 subjects who underwent 10-week diets, the initial ratio was 7.15 with 6- and 10-week values of 8.69 and 9.53, resp. The mean molar ratio of phospholipid to cholesterol in 11 subjects on a 6-week diet was 2.78 before and 2.98 after the diet. In 3 subjects on a 10 week diet, the zero time, 6-week, and 10-week values were 3.16, 3.05, and 2.44, resp. All mean ratios corresponded to moderate supersaturation with cholesterol as compared with established limits for the solubility of cholesterol in aqueous solution. It is suggested that in a population that is accustomed to a high fat intake, subsistence on a low fat diet, over a prolonged period, will reduce the phospholipid to cholesterol ratio.

2405 METABOLISM OF DEOXYCHOLIC ACID IN MAN.

(Eng.) Matern, S.; Sjovall, J.; Pomare, E. W.; Heaton, K. W.; Low-Beer, T. S. (Karolinska Institutet, S-104 01 Stockholm 60, Sweden). *Med. Biol.* 53(2):107-113; 1975.

The metabolism of [24-^{14}C]deoxycholic acid was studied in six patients with cholecystectomy and in two patients with intact gallbladder, all with an intact enterohepatic circulation. Three microcuries of filtered labeled deoxycholic acid in saline were injected i.v. in each patient, and duodenal bile samples were aspirated 24 and 96 hr later; the bile samples were analyzed for metabolites of deoxycholic acid in nonsulfated and sulfated fractions. Two metabolites were identified in hydrolyzed duodenal bile: 3α-hydroxy-12-oxo-5β-cholanoic and 3β,12-α-dihydroxy-5β-cholanoic acids. Quantitative analysis of one sample showed the amounts of these compounds to be only about 2 and 0.5%, resp., of the amount of deoxycholic acid. A small percentage of deoxycholic acid (less than 3%) was found in a fraction having the chromatographic property of conjugated bile acid sulfates. About 15% of the identified metabolites were found in this fraction, which also contained more than 50% of the biliary lithocholate and 90% of the biliary 3β-hydroxy-5-cholenoate. The results support the view that deoxycholic acid undergoes little metabolism during enterohepatic circulation in man.

2406 DIFFERENT SELECTIVITIES IN ACYLATION AND METHYLATION PATHWAYS OF PHOSPHATIDYLCHOLINE FORMATION IN GUINEA PIG AND RAT LIVERS.

(Eng.) MacDonald, G.; Thompson, W. (Dept. Biochemistry, Univ. Toronto, Toronto M5S 1A8, Canada). *Biochem. Biophys. Acta* 398(3):424-432; 1975.

"Indirect pathways" of phosphatidylcholine synthesis were studied *in vivo* in guinea pig and rat livers. Radioactivity from i.p. or intraportally injected 1-acyl-*sn*-glycero-3-phosphorylcholine, doubly labeled in either palmitoyl, glycerol, or phosphoryl moieties, was incorporated largely into disaturated or mixed disaturated-oligoenoic fractions of phosphatidylcholine in guinea pig liver. In rat liver, the tetraenoic class was the most highly labeled, and only very low radioactivity was recovered from disaturated or monoenoic species. The methylation of phosphatidylethanolamine to phosphatidylcholine, as judged by the incorporation of i.p. injected L-[*Me*-^{14}C]methionine, involved selectively tetraenoic and polyenoic (>4 double bonds) classes in rat liver. In guinea pig liver, methylation activity was much lower and it led to the formation principally of dienoic classes of phosphatidylcholine. These experiments confirm that in rat liver, which has a high level of polyunsaturated classes of phosphatidylcholine, the indirect pathways of synthesis give rise chiefly to these classes. However, the priorities in guinea pig liver are different, since the levels of polyunsaturated classes are much lower, and although the indirect pathways of synthesis are operative, they are directed mainly toward the formation of more saturated classes.

2407 TRANSFER OF ESTERIFIED CHOLESTEROL FROM SERUM LIPOPROTEINS TO THE LIVER.

(Eng.) Goodman, Z. D.; Lequire, V. S. (Vanderbilt Univ. Sch. Med., Nashville, TN). *Biochim. Biophys. Acta* 398(2):325-336; 1975.

The fate of cholesteryl esters of the serum lipoproteins was studied in fasted intact Holtzman rats and in isolated perfused rat livers. The lipoproteins of fasting rat serum were labeled *in vitro* with [^{3}H]cholesteryl oleate. Following i.v. injection, the majority of the radioactive ester was rapidly taken up by the liver where hydrolysis of the ester bond occurred. At 5 min, 58% of the injected material was recovered in the liver, 85% of which was still in the ester form, while at 30 min, only 22% of the liver radioactivity was in cholesteryl esters. There was little difference in the rate at which radioactivity was taken up from the different lipoprotein classes. Similar findings were observed in the perfused liver, but there was no change in the concentrations of free or esterified cholesterol in the perfusing medium, indicating that the lipoprotein cholesteryl ester was gaining access to the liver through an exchange of molecules. After uptake, cell fractionation experiments showed that the plasma membranes had the greatest relative amounts of radioactivity, suggesting that this was the site of exchange. Small amounts of radioactivity were recovered in the bile, demonstrating that serum lipoproteins can serve as precursors of at least some of the bile steroids.

2408 ROLE OF MEMBRANES IN BILE FORMATION: COMPARISON OF THE COMPOSITION OF BILE AND A LIVER BILE-CANALICULAR PLASMA-MEMBRANE SUBFRACTION.

(Eng.) Evans, W. H.; Kremmer, T.; Culvenor, J. G. (Natl. Inst. Medical Res., Mill Hill, London NW7 1AA, U.K.). *Biochem. J.* 154(3):589-595; 1976.

Enzymes, proteins, glycoproteins, and lipids of rodent bile (Sprague-Dawley rats or Parke's white mice) were compared with those of a plasma-membrane subfraction originating from the hepatocyte bile-canalicular membrane. Three bile-canalicular glycoprotein enzyme activities were detected in bile. Comparison of the pH optimum and immunoinhibition properties of membrane and bile 5'-nucleotidase activity indicated that they were the same enzyme. Correspondence between membrane and bile alkaline phosphodiesterases also suggested that they were the same enzymes. Activities of Mg^{2+}-stimulated adenosine triphosphatase (a lipid-dependent intrinsic membrane protein) and galactosyltransferase (a Golgi membrane marker) were not detected in bile. Rodent bile contained 15 polypeptide bands that differed radically from those of bile-canalicular membranes. Bands that may correspond in molecular weight to liver plasma-membrane glycoproteins were present at low staining intensities in bile. A major protein of apparent molecular weight 49,500 was present, and albumin was detected by immunodiffusion. The lipid composition of bile and bile-canalicular membrane also differed. Phosphatidylcholine accounted for 82% of rat bile phospholipids, and only trace amounts of phosphatidylinositol, phosphatidylserine, and sphingomyelin were present. The results indicate that in healthy animals, the bile-canalicular membrane is refractory to the action of bile acids during the secretory process. The presence of only small amounts of bile-canalicular membrane components, especially glycoprotein enzymes located at the outer face of the membrane, suggests that these are released from the membrane by bile acids after secretion of bile into the canalicular spaces.

2409 ULTRASTRUCTURAL AND STEREOLOGICAL STUDY ON THE EFFECT OF VITAMIN E ON LIVER MITOCHONDRIAL MEMBRANES.

(Eng.) Frigg, M.; Rohr, H. P. (F. Hoffmann-La Roche & Co., 4002 Basle, Switzerland). *Exp. Mol. Pathol.* 24(2):236-243; 1976.

The effect of vitamin E on liver mitochondrial membranes was studied ultrastructurally and stereologically. Fifteen male hybrid mice (initial weight 20-24 gm) were divided equally into a vitamin E-deficient group, a vitamin E-supplement group, and a standard diet control group. After 17 weeks, left liver lobule tissue samples were obtained. Vitamin E deficiency was determined by a modified hemolysis test using two dialuric acid concentrations (4 mg/l and 16 mg/l). Ultrastructurally, no descriptive differences were observed in the three trial groups. Stereologically, the volume density and mean single volume of the mitochondria were unchanged in all three groups. However, mitochondrial inner membrane surface density was increased significantly and surface-to-volume density ratio was higher in the vitamin E-deficient group than in the other two groups. Mitochondrial inner membrane near enzyme distance (center-to-center distance) was calculated to confirm this evidence of membrane proliferation. The mean distance of the four cytochrome molecules was in the 180-230 A range in the control group. Enzyme distances increased 30-40% in the vitamin E-supplement group, and these dimensions were nearly doubled in the vitamin E-deficient group. The findings indicate that formation of liver mitochondrial inner membrane is enhanced and cytochrome density is reduced in vitamin E deficiency.

2410 EFFECT OF CHRONIC ETHANOL TREATMENT ON METABOLISM OF DRUGS IN VITRO AND IN VIVO.

(Eng.) Khanna, J. M.; Kalant, H.; Yee, Y.; Chung, S.; Siemens, A. J. (Univ. Toronto, Dept. Pharmacology, Ontario, Toronto, Canada). *Biochem. Pharmacol.* 25(3):329-335; 1976.

The effect of chronic ethanol treatment on the metabolism of drugs *in vitro* and *in vivo* was investigated in male Wistar rats. Rats were administered a daily intake of ethanol (10-12 g/kg, 1 month) in either high-fat, adequate-protein (HFAP) or low-fat, high-protein (LFHP) liquid diets. For both HFAP and LFHP diets, there were significant increases in liver weights ($p<0.001$ and $p<0.01$, resp.), microsomal protein ($p<0.05$ and $p<0.02$, resp.), and microsomal metabolism of 10 μmol aminopyrine ($p<0.001$ and $p<0.02$, resp.), 0.59 μmol zoxazolamine ($p<0.01$ and $p<0.005$, resp.), 25 μmol aniline ($p<0.005$ and $p<0.001$, resp.), and 0.3 mmol meprobamate ($p<0.005$ and $p<0.001$, resp.). Morphine (25 μmol) metabolism was increased only after the HFAP diet ($p<0.01$); pentobarbital metabolism was studied only after HFAP diet, and it was increased ($p<0.005$). The increase *in vitro* was highest with aminopyrine (81% with HFAP and 59% with LFHP) and lowest with pentobarbital (25%). The analysis of variance showed highly significant differences among the various drugs. There were significant interaction effects of drugs and ethanol ($p<0.001$) and drugs and fat content ($p<0.05$), but no significant interaction occurred between ethanol and fat or between drugs and ethanol and fat, except in the case of morphine. The increase *in vivo* was greatest with 30 mg/kg meprobamate ($p<0.01$), it was intermediate with 30 mg/kg aniline and 60 mg/kg zoxazolamine, and it was low with 60 mg/kg aminopyrine; it was absent with pentobarbital. It is concluded that chronic ethanol administration does increase the metabolism of drugs *in vitro* and *in vivo*, but the diversity of effects on different drugs cannot be explained by a single mechanism.

2411 CHANGES IN THE HEPATIC MICROSOMAL ENZYME ACTIVITY DURING LONG-TERM ETHANOL FEEDING IN RAT.

(Eng.) Luoma, P.; Vorne, M. (Dept. Pharmacology, Univ. Oulu, SF-90220 Oulu 22, Finland). *Acta Pharmacol. Toxicol.* 38(3):260-266; 1976.

The effect of long-term ethanol administration on the hepatic microsomal enzymes was investigated in male Sprague-Dawley rats. The animals were given 15% (volume/volume) ethanol *ad libitum* in the drinking water for 4, 6, and 10 weeks. Ethanol caused significant changes in the hepatic microsomal metabolism of methylaniline and *p*-nitrobenzoic acid, and in the microsomal protein and cytochrome P-450 contents, as compared with controls. The effect of ethanol on these parameters was time-related, and maximal changes were measured after 2 weeks of drinking ethanol, after which the effect of ethanol diminished. Within this period, the *N*-demethylation of methylaniline was increased by 63%, and nitroreduction of *p*-nitrobenzoic acid was inhibited by 50%. The microsomal protein content was increased after 2 weeks of drinking ethanol by 30%, and the cytochrome P-450 content by 96%. Glucose-6-phosphate dehydrogenase activity in the 105,000 x *g* supernatant fraction was increased during the whole experiment, and after drinking ethanol for 10 weeks, it was stimulated by 116%. It is suggested that the decreases in the effects caused by ethanol may be related to the development of liver damage during long-term ethanol usage, or they may be caused by some kind of adaption to ethanol.

2412 THE ACTIONS OF AVENACIOLIDE AND ETHANOL ON GLUCOSE METABOLISM AND ON RELATED ENZYME ACTIVITIES IN THE ISOLATED PERFUSED RAT LIVER.

(Eng.) Wimhurst, J. M.; Harris, E. J. (University Coll. London, Dept. Biophysics, Gower St., London WC1E 6BT, England). *Biochim. Biophys. Acta* 437(1): 51-61; 1976.

The metabolic response of male Wistar rat livers to perfusion with 165 mg/100 ml ethanol, with and without 47 mM avenaciolide, was determined by measuring the perfusate levels of glucose, lactate, pyruvate, β-hydroxybutyrate, ethanol, amino acids, urea, and lipid. Analysis of the perfused livers showed changes in the activities of some of the key enzymes of glycolysis, gluconeogeneis, and lipogenesis. Ethanol perfusion decreased the levels of phosphofructokinase ($p<0.02$), glucokinase ($p<0.01$), and cytosolic isocitrate dehydrogenase ($p<0.05$), while avenaciolide lowered pyruvate carboxylase ($p<0.05$), phosphoenolpyruvate carboxykinase ($p<0.01$), and glucokinase ($p<0.02$). Isocitrate dehydrogenase and phosphofructokinase were unchanged, but the ionophore increased the level of fructose-1,6-diphosphatase ($p<0.05$). Ethanol plus avenaciolide showed the same pattern as ethanol alone, together with the decrease in phosphoenolpyruvate carboxykinase ($p<0.001$) found with avenaciolide. Neither ethanol nor avenaciolide had any effect on hexokinase, pyruvate kinase, or acetyl-CoA carboxylase. There were small changes in glucose-6-phosphatase and malic enzyme, and a tendency for citrate lyase levels to decline in avenaciolide perfusions. It is concluded that enzyme levels in perfused liver concentrations can be altered by ethanol administration.

2413 PROTECTIVE EFFECT OF CYSTEINE ON THE INHIBITION OF MITOCHONDRIAL FUNCTIONS BY ACETALDEHYDE.

(Eng.) Cederbaum, A. I.; Rubin, E. (Mount Sinai Sch. Medicine, New York, NY 10029). *Biochem. Pharmacol.* 25(8):963-973; 1976.

The ability of cysteine to reverse the acetaldehyde-induced inhibition of several mitochondrial functions was studied in rat liver mitochondria. Cysteine, *in vitro*, afforded protection against the depression of CO_2 production from palmitate, octanoate, and α-ketoglutarate by acetaldehyde. Relief occurred when the concentrations of cysteine and acetaldehyde were equimolar; greater relief was produced in the presence of excess cysteine. Acetaldehyde had no effect on glutamate-linked state 4 oxygen consumption, whereas the state 3 rate was inhibited. Cysteine almost completely relieved the inhibition of state 3 oxygen uptake, while the state 4 rate was slightly increased. Similar results were obtained with several other NAD^+-dependent substrates. The oxidation of succinate was inhibited only by much higher concentrations of acetaldehyde than those that inhibited the oxidation of NAD^+-dependent substrates. This inhibition was not affected by cysteine. Thiols containing free amino and free sulfhydryl groups in close proximity were the most effective in relieving the inhibition by acetaldehyde. Although a small protective effect was observed, cysteine did not significantly prevent the inhibition of oxidative phosphorylation by acetaldehyde. However, the mitochondria remained coupled in the presence of acetaldehyde plus cysteine. The ability of cysteine and acetaldehyde to interact was demonstrated. It is suggested that cysteine exerts its protective effect by forming a complex with acetaldehyde, thereby preventing acetaldehyde from interacting with the mitochondria.

2414 INFLUENCE OF THE DIET ON THE METABOLISM OF ACETALDEHYDE IN RATS.

(Eng.) Marchner, H.; Tottmar, O. (Inst. Zoophysiology, Univ. Uppsala, Box 560, S-751 22 Uppsala, Sweden). *Acta Pharmacol. Toxicol.* 38(1):59-71; 1976.

Liver acetaldehyde dehydrogenases, the hepatic output of acetaldehyde, and the rate of ethanol elimination were studied in two groups of female Sprague-Dawley rats, which were fed two different commercial standard diets (diet 1 and diet 2). Diet 1 contained extra trace elements (Fe, Cu, Co, I_2, Mn, and Zn) and vitamins (B12, K1, niacin, and choline chloride), which were not included in diet 2. Diet 2 contained 0.005% butylhydroxytoluene. The activity of the mitochondrial low-K_m enzyme was 2-3 times lower in rats fed on diet 1 as compared to rats fed on diet 2, whereas only slight differences were found in the activities of the high-K_m enzymes in the mitochondrial, the microsomal, and the cytosol fractions. No differences were observed between the two groups in the activities of alcohol dehydrogenase, glutamate dehydrogenase, glucose-6-phosphatase, or malic enzyme. Ethanol (1.70 g/kg) was administered i.p. in saline as a 10% (weight/volume) solution. The rate of ethanol elimination was 15% lower and the acetaldehyde level in the blood was 2-4 times higher in rats fed diet 1 as compared to rats fed diet 2. When the diets were interchanged between the two groups, the activity of the low-K_m enzyme increased or decreased twofold within 12 hr. Starvation increased the activity of the low-K_m enzyme in rats fed diet 1, but it had no effect on the activity in rats fed diet 2. The results suggest that diet 1 contains an inhibitor of the low-K_m enzyme, and that dietary factors may be of importance in the regulation of the hepatic output of acetaldehyde during ethanol metabolism.

2415 EFFECTS OF CLOFIBRATE ON SOME MICROSOMAL HYDROXYLATIONS INVOLVED IN THE FORMATION AND METABOLISM OF BILE ACIDS IN RAT LIVER.

(Eng.) Angelin, B.; Bjorkhem, I.; Einarsson, K. (Karolinska Institutet, Stockholm, Sweden). *Biochem. J.* 156(2): 445-448; 1976.

The liver microsomal metabolism of [4-^{14}C]cholesterol, endogenous cholesterol, 7α-hydroxy-4-[6β-^{3}H]cholesten-3-one, 5β-[7β-^{3}H]cholestane-3α,7α-diol, and [^{3}H]lithocholic acid was studied in control and 0.3% clofibrate (ethyl *p*-chlorophenoxyisobutyrate)-treated Sprague-Dawley rats. The extent of 7α-hydroxylation of exogenous [4-^{14}C]cholesterol and endogenous cholesterol was the same in the two groups of rats. The extent of 12α-hydroxylation of the two major metabolites, 7α-hydroxy-4-cholesten-3-one and 5β-cholestane-3α,7α-diol was increased by about 60 and 120%, resp., by clofibrate treatment. The 26-hydroxylation of 5β-cholestane-3α,7α-diol was not significantly affected by clofibrate. The 6β-hydroxylation of lithocholic acid was about 80% higher in the clofibrate treated animals than in the controls. The finding that 12α-hydroxylase was stimulated by clofibrate treatment may have some bearing on recent observations in patients with hyperlipoproteinemia type II (hypercholesterolemia) who have a low ratio between cholic acid and chenodeoxycholic acid synthesis. During treatment with clofibrate, the combined synthesis of cholic acid and chenodeoxycholic acid was unchanged, but the ratio between them increased in five out of six patients.

2416 EFFECTS OF ETHINYL ESTRADIOL AND PHENOBARBITAL ON BILE ACID SYNTHESIS AND BILIARY BILE ACID AND CHOLESTEROL EXCRETION.

(Eng.) Davis, R. A.; Kern, F., Jr. (Univ. Colorado Sch. Medicine, Denver, CO). *Gastroenterology* 70(6):1130-1135; 1976.

The effects of ethinyl estradiol on bile acid synthesis were measured in Sprague-Dawley rats. The effect of simultaneous phenobarbital treatment on reversing the ethinyl estradiol-induced changes in bile composition was also studied. Bile acid synthesis, calculated from respiratory $^{14}CO_2$ derived from the catabolism of [26 or 27-^{14}C]cholesterol to bile acids in rats with intact enterohepatic circulations, decreased 50% after 5 days of ethinyl estradiol treatment (5 mg/kg/day). Maximal derepressed bile acid synthesis was also reduced 50% by ethinyl estradiol treatment. Because ethinyl estradiol did not alter biliary cholesterol excretion, bile contained less bile acid relative to cholesterol. Hepatic bile acid concentration was not increased by ethinyl estradiol treatment. Because the inhibitory effect of ethinyl estradiol on bile acid synthesis required 5 days of treatment, it is concluded that bile acid synthesis probably was not reduced by negative feedback repression of 7α-hydroxylase, the rate-limiting enzyme in bile acid synthesis, which has a half-life of 2-3 hr. During the first 14 hr after bile duct cannulation, before acid pool depletion, ethinyl estradiol-treated rats excreted less than half as much bile acid and the same amount of cholesterol as controls. The bile acid to cholesterol ratio was therefore decreased. Rats, which were treated simultaneously with phenobarbital (80 mg/kg/day) and ethinyl estradiol excreted significantly more bile acid than rats, which were treated with ethinyl estradiol alone, but biliary cholesterol excretion was not increased. The proportion of biliary bile acid relative to cholesterol was thereby restored to the control value. After 14 hr of bile drainage and depletion of the bile acid pool, rats treated with ethinyl estradiol and those treated with phenobarbital-ethinyl estradiol excreted the same amount of bile acid. Thus, the administration of phenobarbital plus ethinyl estradiol increases bile acid pool size and biliary acid excretion, but it does not increase bile acid synthesis.

2417 THE EFFECT OF THYROID HORMONE ON BILE SALT-INDEPENDENT BILE FLOW AND NA^+, K^+-ATPase ACTIVITY IN LIVER PLASMA MEMBRANES ENRICHED IN BILE CANALICULI.

(Eng.) Layden, T. J.; Boyer, J. L. (Westside Veterans Admin. Hosp., Univ. Illinois, Chicago, IL 60612). *J. Clin. Invest.* 57(4): 1009-1018; 1976.

The relation between bile salt-independent canalicular flow and ATPase activity in liver plasma membranes (LPM) that are enriched in bile canaliculi was studied in control, hyperthyroid, and hypothyroid rats. Canalicular bile production was significantly increased in hyperthyroid rats (3.19 µl/min/g liver) as compared with controls (2.27 µl/min/g liver), and it diminished in hypothyroid animals (1.58 µl/min/g liver). Although bile salt excretion was also increased in hyperthyroid animals, the stimulation in canalicular secretion was primarily related to enhancement of the bile salt-independent fraction of flow (2.47 µl/min/g liver in hyperthyroid rats versus 1.67 µl/min/g liver in controls). LPM Na^+, K^+-ATPase activity doubled in hyperthyroid animals (21.5 ± 5.8 versus 10.7 ± 3.1 µmol Pi/mg protein/hr), while Mg^{++}-ATPase activity remained unchanged, and 5'-nucleotidase activity increased to a small but significant extent ($p<0.05$). In hypothyroid rats, bile salt excretion remained unchanged from control values so that the reduced secretion was secondary to an inhibition of bile salt independent secretion (1.19 µl/min/g liver). Na^+, K^+-ATPase activity in LPM's from hypothyroid animals decreased by nearly 50% (5.4 µmol Pi/mg protein/hr), although comparable reductions (30-45%) in the specific activity of Mg^{++}-ATPase and 5'-nucleotidase were also observed. Administration of L-thyroxine (20 µg/100 g body weight) to hypothyroid animals restored both bile salt-independent canalicular secretion and membrane enzymes to control values within 2-4 days. Sodium dodecyl sulfate gel electrophoresis demonstrated no significant changes in LPM protein fractions in any of the treatment groups. These studies indicate that thyroid hormone has a parallel effect on bile salt-independent canalicular secretion and LPM Na^+, K^+-ATPase activity.

2418 EFFECT OF BILE SALTS ON THE HEPATIC REGULATION OF SERUM LECITHIN:CHOLESTEROL ACYLTRANSFERASE ACTIVITY.

(Eng.) Ho, K. J.; Cisternas, R.; Boyd, G. S. (Dept. Pathology, Univ. Alabama Birmingham, Birmingham, AL). *Atherosclerosis* 23(2):145-153; 1976.

The effect of bile salts on lecithin:cholesterol acyltransferase (LCAT) activity was studied in three groups of Wistar rats. In rats, which were fed a 4% cholestyramine diet for 15 days, a 30% increase in serum LCAT activity was detected by radioimmunoassay, and this was accompanied by a simultaneous decrease of the serum esterified cholesterol concentration; the serum free cholesterol concentration remained unchanged. After bile duct ligation, the serum free cholesterol concentration increased progressively, whereas the mean serum LCAT activities of three groups of rats killed 2, 6, and 8 hr after ligation were 39, 51, and 140%, resp., of that of the sham-operated control rats. Eighty-two rats were used in 23 isolated liver perfusion studies including 10 "perfusions" performed without the liver circuit. These studies revealed a remarkable degree of nonenzymic degradation of the enzyme during perfusion. Perfusion of livers from rats previously fed a 4% cholestyramine diet resulted in a delay of the initial decline of perfusate LCAT activity associated with the maintenance of a steady state during the third and fourth hours of the perfusion. Such phenomena were abolished by addition of sodium taurocholate to the perfusate (5 mg/dl), suggesting a direct inhibitory effect of bile salts on the hepatic synthesis and release of LCAT.

2419 IS FATTY LIVER INDUCTION A GENERAL FEATURE OF THE ADMINISTRATION OF FOREIGN SULFHYDRYL COMPOUNDS?

(Eng.) Sabourault, D.; Giudicelli, Y.; Nordmann, R.; Nordmann, J. (Hospital de la Salpetriere, 47, Bd. de l'Hopital, 75013, Paris, France). *Biochim. Biophys. Acta* 431(2):241-248; 1976.

The effects of 2-mercaptoethanol on the liver of Wistar rats were compared with those of 2-mercaptoacetate and 2-mercaptopropionate to determine whether fatty liver is a common result of the administration of thiol-bearing compounds. The i.p. administration of 2-mercaptoethanol or 2-mercaptoacetate (40 µM/100 g body weight) induced a fatty liver, a marked and early increase of free fatty acids, and a decrease of triacylglycerol and phospholipids in the blood. These changes were accompanied by a decrease of the ketone body level and the β-hydroxybutyrate/acetoacetate ratio in the liver. Under the same experimental conditions, however, administration of 2-mercaptopropionate failed to induce a fatty liver and did not modify the hepatic ketone body level of the blood triacylglycerol and free fatty acid levels. The results indicate that fatty liver induction is not a general feature of foreign thiols and suggest that increased peripheral fat mobilization, as well as decreased hepatic lipoprotein synthesis and/or release, are responsible for the 2-mercaptoethanol- and 2-mercaptoacetate-induced fatty liver.

2420 ENHANCEMENT OF THE IMMUNE RESPONSE BY A CATABOLIC PRODUCT OF NORMAL RABBIT IgG. EFFECT OF $F(ab')_2$-LIKE FRAGMENT. (Eng.) Kulberg, A. J.; Evnin, D. N.; Tarkhanova, I. A. (N. F. Gamaleya Inst. Epidemiology and Microbiology, Moscow 123098, USSR). *Immunology* 30(5):715-722; 1976.

A factor in the serum of partially hepatectomized rabbit, taken 4 hr after operation, causing the enhancement of the immune response to sheep SRBC in homologous recipients was investigated. The serum of partially hepatectomized rabbits contained a 5.2S IgG fragment antigenically related to peptic $F(ab')_2$ fragment. The i.v. injection of this fragment together with SRBC into rabbits resulted in enhancement of antibody-forming cell (PFC) response and hemagglutinin production. Similar enhancing effect was produced by peptic $F(ab')_2$ fragment obtained from rabbit IgG devoid of anti-SRBC antibodies. Sera of partially hepatectomized rabbits did not contain $F(ab')_2$-like fragments and failed to enhance the immune response if the animals were treated with a proteinase inhibitor ("Trasylol"), indicating that the fragment was a catabolic product of IgG. The results suggest a regulation of immunoglobulin synthesis by a split product of autologous IgG.

2421 HEPATIC BLOOD FLOW AND CARDIAC OUTPUT AFTER PORTA-CAVAL ANASTOMOSIS IN THE RAT. (Eng.) Liehr, H.; Grun, M.; Thiel, H. (Medizinische Universitatsklinik, Josef-Schneider-Strasse 2, 8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(1):31-40; 1976.

Hepatic hemodynamics and cardiac output were measured in FW 49 strain rats 3, 6, 14, and 28 days after portacaval anastomosis (PCA) using the flow fraction distribution method (^{131}I-labeled albumin) of cardiac output. Cardiac output was calculated, using Vierordt's principle, from blood volume and measurement of indocyanine green-appearance time (ICG-AT) by ear densitometry. Three days after PCA, cardiac output was increased to 38.7 ± 5.0 ml/min/100 g body weight (normal 23.8), due to an increase of blood volume from 6.3 to 7.5 ml/100 g and a decrease of ICG-AT from 3.6 to 2.8 sec. Arterial hepatic flow fraction of cardiac output increased to 8.7 ± 2.8% (control, 5.5 ± 2.4%). Changes were observed up to day 28. Hepatic blood flow per gram liver tended to stabilize, but was still decreased at day 28 (1.5 ml/min/g liver, control 2.0). It is concluded that the typical hemodynamic changes in human liver cirrhosis can be reproduced by PCA alone. These changes are considered to be compensatory mechanisms for a reduced portal liver blood flow, but these mechanisms do not compensate completely.

2422 COMPARISON OF SULFOBROMOPHTHALEIN (BSP) AND SULFOBROMOPHTHALEIN GLUTATHIONE (BSP-GSH) DISPOSITION UNDER CONDITIONS OF ALTERED LIVER FUNCTION AND IN THE ISOLATED PERFUSED RAT LIVER. (Eng.) Yam, J.; Reeves, M.; Roberts, R. J. (Univ. Iowa, Toxicology Center, Iowa City, IA 52242). *J. Lab. Clin. Med.* 87(3):373-383; 1976.

A comparative study of the disposition of sulfobromophthalein (BSP) and sulfobromophthalein glutathione (BSP-GSH) was conducted in Sprague-Dawley rats. Investigations were performed in control rats, in rats under conditions of altered liver function induced by either 80 mg/kg phenobarbital or α-naphthylisothiocyanate (ANIT) administered i.p., and in the isolated perfused rat liver. The BSP or BSP-GSH was administered, i.v., either as a single bolus injection at a dose of 120 μM/kg or as a constant infusion at a rate of 3.6 μM/kg/min or via the external jugular cannula at a dose of 50 nM/kg/min. The concentration of dye in samples of plasma or bile was determined colorimetrically. A significantly higher percentage of BSP (61 ± 4% versus 48 ± 1% BSP-GSH) was found in the plasma while a higher percentage of BSP-GSH (20 ± 3% versus 9 ± 1% for BSH) was recovered from the liver 1 min after dye injection. There were no differences in the kidneys. When rat livers were perfused with 200 ml perfusion medium to which 4 μM of BSP or BSP-GSH were added, the main recovery of dye was 98 ± 4 and 99 ± 4% for BSP and BSP-GSH, resp. However, with dye infusion of 3.6 μM/kg/min, phenobarbital significantly enhanced the rate of biliary excretion of BSP, but not of BSP-GSH, and ANIT treatment had a greater inhibitory effect on biliary excretion of BSP-GSH than of BSP. The results indicate that in liver function test studies, the selection of dye, the method of administration, and the time of sampling are critically important and must be taken into consideration.

2423 ORTHOTOPIC LIVER TRANSPLANTATION: AN EXPERIMENTAL STUDY ON MECHANISMS OF HEMORRHAGIC DIATHESIS AND THROMBOSIS. (Eng.) Schalm, S. W.; Terpstra, J. L.; Achterberg, J. R.; Noordheck Hegt, V.; Haverkate, F.; Popescu, D. T.; Krom, R. A. F.; Veltkamp, J. J. (Mayo Clinic, Rochester MN 55901). *Surgery* 78(4):499-507; 1975.

The mechanisms of hemorrhagic diathesis after recirculation of the graft and hepatic artery thrombosis following liver transplantation was investigated. Coagulation, fibrinolysis, and platelet function were prospectively studied before and after 28 orthotopic liver transplantations in dogs and pigs. In addition, the arterial anastomoses were evaluated routinely by angiography and, after removal at reintervention or autopsy, they were inspected for thrombosis and tested for fibrinolytic activity and fibrin deposition. Prolonged bleeding without concomitant thrombocytopenia occurred only in the nine dogs with liver transplants that had been previously preserved for 3 to 6 hr prior to the transplant operation. As only two of the nine dogs had postoperative hemorrhage of clinical significance, surgically imperfect hemostasis, facilitated by an acquired platelet dysfunction, is considered to be the principal cause of hemorrhage. Thrombosis of the arterial anastomosis was found in 38% of animals in which an end-to-end anastomosis was made, but it was not encountered with celiac artery-aorta anastomoses. Local factors due to surgical technique therefore appear most important in the pathogenesis of thrombosis of the hepatic artery anastomosis, although the postoperative hyperfibrinogenemia and diminished local and systemic fibrinolytic activity may also contribute.

2424 EFFECT OF STRESS AND ASPIRIN ON EXTRAHEPATIC PORTAL HYPERTENSION IN RATS. (Eng.) Grosfeld, J. L.; Phelps, T. O.; Jesseph, J. M. (James Whitcomb Riley Hosp. Children, 1100 W. Michigan St., Indianapolis, IN 46202). *J. Pediatr. Surg.* 10(5):609-615; 1975.

The effect of stress and aspirin administration was studied in Wistar rats after the induction of extrahepatic portal hypertension by portal venous constriction (PVC). Portal pressures on the fourth postconstriction day were significantly elevated in these rats (28.9 ± 6.6 cm H_2O) when compared to controls (8.9 ± 2.2 cm H_2O). Splenoportograms showed decreased hepatic flow and venous collaterals. Histologic sections showed gastric mucosal congestion in PVC rats. Gastric acid production and H^+ ion equilibration were similar in PVC and control rats. Rats with portal hypertension had a significant increase ($p<0.001$) in mucosal erosions when subjected to a 7-hr restraint stress on the fourth postoperative day. Erosion formation in other animals, which had also been restrained, was significantly augmented by 3 days of aspirin administration (300 mg/day). These data demonstrate an increased susceptibility of PVC rats to nonhemorrhagic stress. This response is clearly augmented by aspirin treatment. Gastric congestion and the known effect of aspirin on gastric mucosal permeability and the gastric mucosal barrier are implicated in these observations. The findings correlate with clinical observations and strongly suggest that aspirin therapy be avoided in children with extrahepatic portal hypertension.

2425 β-ADRENERGIC RECEPTORS IN RAT LIVER: EFFECTS OF ADRENALECTOMY. (Eng.) Wolfe, B. B.; Harden, T. K.; Molinoff, P. B. (Univ. Colorado Medical Center, 4200 East Ninth Ave., Denver, CO 80220). *Proc. Natl. Acad. Sci. USA* 73(4):1343-1347; 1976.

2467 RIBOSOME STRUCTURE AND CHYLOMICRON FORMATION IN RAT INTESTINAL MUCOSA. (Eng.) Yousef, I. M.; O'Doherty, P. J. A.; Whitter, E. F.; Kuksis, A. (Dept. Pathology, Univ. Toronto, Toronto, Canada, M5G 1L6). *Lab. Invest.* 34(3):256-262; 1976.

Sucrose gradient sedimentation and electron micrograpic studies were made on the ribosomes of intestinal mucosa cells isolated from control, bile fistula, and puromycin-treated Wistar rats. In com parison to controls, there was a 40-60% decrease in polysome content of the cells following i.p. admini tration of 15 mg puromycin or deprivation of lumina choline by creation of a bile fistula. Feeding of

) mg lysolecithin or 5 mg choline to the bile fistu-
a rats, or addition to the isolated cells *in vitro*
).5 mg lysolecithin/tube or 0.1 mg choline chloride/
ıbe), resulted in a complete restoration of the
olysome profile along with lipoprotein synthesis
ıd chylomicron release. Addition of lysolecithin
o isolated cells treated with puromycin *in vitro*
l mg/tube) also brought about a reaggregation of the
ibosomes and a reactivation of phospholipid bio-
ynthesis, without significant effect on the lipo-
rotein synthesis and release of chylomicrons. Choline
ad no detectable effect on phospholipid synthesis
r ribosome aggregation, when fed to puromycin-treated
ats or when added to puromycin-treated cells *in*
tro. The results suggest that chylomicron forma-
ion and the release by the mucosal cells depend
pon intact rough endoplasmic reticulum, an active
rotein, and phospholipid biosynthesis. The role
f lysolecithin in this process is rationalized on
ne basis of its ability to supply a precursor of
ecithin as well as a surfactant, which affects the
ggregation, or membrane rebinding of ribosomes, or
oth.

68 γ-GLUTAMYLTRANSPEPTIDASE IN INTESTINAL BRUSH BORDER MEMBRANES.

(Eng.) Curthoys,
P.; Shapiro, R. (Univ. Pittsburgh, Sch. Medicine,
ttsburgh, PA 15261). *FEBS Lett.* 58(1):230-233;
75.

Glutamyltranspeptidase activity in the rat small
testine was studied. Crude homogenates of rat
dney and of isolated villus cells were homogenized
phosphate-buffered saline. γ-Glutamyltranspepti-
se activity was measured with 3 mM γ-glutamyl-*p*-
troanilide and 50 mM imidazole at pH 7.2. The
ecific activity of γ-glutamyl-transpeptidase in
olated villus cells of the small intestine was
proximately 100-fold less than that observed in
ude homogenates of kidney. However, in the ab-
nce of malate, the addition of various amino
ids caused a similar activation of γ-glutamyl-
anspeptidase in both preparations. In addition,
quential elution of villus to crypt cells and
eparation of intestinal brush border membranes
dicated that the γ-glutamyltranspeptidase is
calized primarily in the brush border membrane
the villus cells of the rat small intestine.

69 RELEASE OF PEPTIDE HYDROLASES DURING INCUBATION OF INTACT INTESTINAL SEGMENTS IN TRO.

(Eng.) Silk, D. B. A.; Kim, Y. S. (Veterans
min. Hosp., San Francisco, CA 94121). *J. Physiol.*
ondon) 258(2):489-497; 1976.

testinal segments from female Wistar rats were
cubated in isotonic saline *in vitro* and release
peptidase hydrolase enzymes into the incubation
dia was examined over a 90-min study period.
says of chemical activities were performed and
analysis was made of electrophoretic mobilities
released enzymes on starch gel. The dipeptides
ycyl-L-phenylalanine (Gly-Phe) and L-phenylalanyl-
ycine (Phe-Gly) were chosen as substrates for
termining peptide hydrolase activity. Release of Gly-Phe and Phe-Gly hydrolase activity into saline media maintained at 0-4 and 37 C was linear with respect to time. The media contained much greater amounts of Gly-Phe hydrolase activity than Phe-Gly hydrolase activity. Similar proportions of intestinal mucosal Gly-Phe (18.3) and Phe-Gly (15.1%) hydrolase activities were released into saline media maintained at 0-4 C. In contrast, a significantly higher proportion of intestinal mucosal Gly-Phe (14.5 ± 4.3%) than Phe-Gly (7.5 ± 1.9%) hydrolase activity was released into saline media maintained at 37 C ($p<0.05$). The bulk of enzyme activity (>83.9%) released into saline maintained at 0-4 and 37 C was sensitive to *p*-hydroxymercuribenzoate (9.5 mM). The results of zymogram studies taken in conjunction with the chemical assay data indicate that peptide hydrolases released from intact intestinal tissue *in vitro* originate from the cytoplasm of mucosal cells rather than from the brush border. It is concluded that compared to the *in vivo* situation, cytoplasmic peptide hydrolases are released from intestinal tissue very rapidly *in vitro*.

2470 PROSTAGLANDIN PRODUCTION BY RABBIT ISOLATED JEJUNUM AND ITS RELATIONSHIP TO THE INHERENT TONE OF THE PREPARATION.

(Eng.) Ferreira, S. H.; Herman, A. G.; Vane, J. R. (Faculdade de Medicina, Ribeirao Preto, S.P., Brazil). *Br. J. Pharmacol.* 56(4):469-477; 1976.

Prostaglandin release was studied in isolated rabbit jejunum in which muscle tone was changed by several procedures. Preparations bathed in Krebs solution at 37 C in an isolated organ bath maintained a continuous submaximal muscle contraction, referred to as inherent "tone." Prostaglandins E_2 and $F_{2\alpha}$ were continuously generated by the intestine and released into the bathing fluid. The amounts released first declined over 2 hr and then steadily increased. The release was also greater after 48 hr storage at 4 C and after mechanical damage. There was no change in prostaglandin release when the jejunum was contracted by acetylcholine or physostigmine or relaxed by adrenalin hyoscine, papaverine, dinitrophenol, or calcium-free Krebs solution. Addition to the bathing fluid of the prostaglandin precursor, arachidonic acid, did not increase the release of prostaglandins although it contracted the tissue. Thus, output of prostaglandins from the tissue was not limited by substrate concentration but more probably by the capacity of the prostaglandin synthetase. Indomethacin treatment or bubbling the bathing fluid with N_2 (instead of O_2) decreased or abolished prostaglandin formation and was accompanied by loss of tone of the isolated preparation. Rabbit jejunum stored in Krebs solution containing indomethacin initially released little or no prostaglandin into the bathing fluid. However, prostaglandin release increased with repeated washing of the preparation. The results suggest that intramural prostaglandin production contributes to the inherent tone of the rabbit jejunum, that trauma increases prostaglandin production, and that the inhibitory effects of anoxia are linked with the lack of prostaglandin production and activity.

2471 PROSTAGLANDIN E IN CHOLERA TOXIN-INDUCED INTESTINAL SECRETION: LACK OF AN INTERMEDIARY ROLE. (Eng.) Hudson, N.; El Hindi, S.; Wilson, D. E.; Poppe, L. (Duke Univ., Medical Center, Durham, NC). *Am. J. Dig. Dis.* 20(11):1035-1039; 1975.

The suggestion that prostaglandin E (PGE) may mediate cholera-toxin effects was investigated. Closed jejunal loops in New Zealand rabbits were injected *in vivo* with 2 cm^3 of isotonic phosphate buffer containing 10 $\mu g/cm^3$ of purified cholera toxin and were compared to similar loops in the same animal injected with buffer. Preliminary studies indicated that 20 μg of cholera toxin produced the greatest volume of fluid secretion at 4 hr; this dosage was used throughout the study. Loop mucosal homogenates and intestinal secretions were analyzed by radioimmunoassay for cyclic AMP (cAMP) and PGE concentrations. Cholera toxin produced significant increases in mucosal and intestinal fluid cAMP at 2 and 4 hr; however, there were no significant increases in PGE in the toxin-treated loops when compared to the control loops. In addition, there was no correlation between cAMP and PGE in the same samples. These studies indicate that cholera toxin stimulates intestinal cAMP and secretion independent of PGE synthesis, and provide evidence against a specific role for PGE in mediating cholera-toxin effects.

2472 EFFECTS OF PREDNISOLONE ON THE SMALL INTESTINAL MUCOSA OF THE RAT. (Eng.) Batt, R. M.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Road, London W12 OHS, England). *Clin. Sci. Mol. Med.* 50(6):511-523; 1976.

The effects of prednisolone [1.55 μmol (0.75 mg)/kg body weight, 7 days] on mucosal function, enzymology, lysosomal membrane fragility, morphology, and cell kinetics were examined in proximal jejunum and distal ileum of male Wistar rats. Intestinal function was assessed by examining the kinetics of D-galactose absorption *in vivo* in 30-cm segments of proximal jejunum and distal ileum with a recirculation perfusion apparatus. The maximal absorptive capacity for galactose was significantly greater in both the jejunum and the ileum of the steroid treated animals. This was due to an increase in carrier-mediated transport in the individual enterocytes and not to a change in the cell population. The Michaelis constant for galactose was not significantly altered by prednisolone. The activities of three brush border enzymes (leucyl-beta-naphthylamidase, neutral α-glucosidase, and β-glucosidase) and one basal lateral membrane enzyme (5'-nucleotidase) in isolated enterocyte preparations were increased in isolated enterocyte preparations from the jejunum and ileum of the steroid group. Lysosomal membrane fragility was unaltered in the prednisolone-treated group. Morphometrical observations confirmed that the size of the enterocyte population was unaltered by prednisolone. Studies on cell kinetics indicate that the effects of prednisolone are due to a direct action on the enterocyte and not to secondary changes in migration rate. It is concluded that the main site of prednisolone action appears to be the brush border, where there are increases in absorptive function and in enzyme activities, although there are changes in other organelles such as the mitochondria.

2473 THE EFFECT OF INTESTINAL DISTENSION AND OF SECTION THICKNESS ON COUNTS OF EPITHELIAL NUCLEI IN THE RAT SMALL INTESTINE. (Eng.) Clarke, R. M. (Dept Human Morphology, University Park, Nottingham NG7 2RD, England). *J. Microsc. (Oxf.)* 103(3):333-341; 1975.

A no-overlap method for counting the number of epithelial nuclei in a section of male Wistar rat intestinal villus is described. The number of counts was independent of section thickness over the range of 4-10 μm. Nuclei counts were determined in villi and crypts of rat small intestine, which were fixed either in the collapsed state or were distended by a hydrostatic pressure of 350 mm of water. There was no significant difference between the number of nuclei in these two conditions. Distension reduced the absolute height of the villi ($p<0.025$) and increased their absolute width at the base ($p<0.01$). Absolute crypt depth was unaffected. This technique may be used to discover the relation between nuclear counts of villus height and base width and the total epithelial cell population of a villus. It may also be useful for determining the relation between absolute measurements of villus height and base width and total surface area.

2474 OXIDATIVE METABOLISM OF FOREIGN COMPOUNDS IN RAT SMALL INTESTINE: CELLULAR LOCALIZATION AND DEPENDENCE ON DIETARY IRON. (Eng.) Hoensch, H.; Woo, C. H.; Raffin, S. B.; Schmid, R. (Gastroenterology Unit, Univ. Tubingen, Tubingen, W. Germany). *Gastroenterology* 70(6):1063-1070; 1976.

The effects of dietary iron on intestinal cytochrome P-450 content and oxidative metabolism of foreign compounds was measured in the intestinal mucosa of male rats. Activities of benzpyrene hydroxylase, *p*-nitroanisole *O*-demethylase, and NADPH-cytochrome P-450 reductase and cytochrome P-450 content were 3 to 10 times higher in epithelial cells of the upper villus than in mucosal crypt cells. Villous tip cells of the upper small intestine exhibited much higher cytochrome P-450 content and drug-metabolizing enzyme activity than did tip cells of lower intestinal segments. In rats fed commercial chow diet, cytochrome P-450 content and drug-metabolizing enzyme activity in villous tip cells of duodenal mucosa were higher than in animals fed a semisynthetic diet, but cytochrome b_5 and NADPH-cytochrome P-450 reductase were unaffected. On restriction of dietary iron intake, cytochrome P-450 and oxidative enzyme activity fell sharply, but were completely restored in 24 hr by p.o. iron supplementation, whereas parenteral iron administration was ineffective. These findings suggest that intestinal drug metabolism is localized primarily in the upper villous cells of the proximal intestinal mucosa, that cytochrome P-450 is synthesized in maturing epithelial cells as they migrate from the crypts to the tip of the mucosal villi, and that this process is dependent upon absorption of iron from the intestinal lumen.

GENERAL

2483 PROLIFERATIVE KINETICS OF LARGE AND SMALL INTRAEPITHELIAL LYMPHOCYTES IN THE SMALL INTESTINE OF THE MOUSE. (Eng.) Ropke, C.; Everett, N. B. (Dept. Biological Structure, Univ. Washington, Seattle, WA). *Am. J. Anat.* 145(3):395-408; 1976.

The proliferative kinetics of intestinal intraepithelial lymphocytes (IL) were evaluated in BALB/C mice. By inducing mitotic arrest, large IL, constituting about 50% of the IL, showed a mitotic rate of 2.3. Autoradiographic results obtained after two different schedules of ^{3}H-thymidine injections showed that 30% of the large IL were in DNA synthesis, and that the large IL were renewed at a rate comparable to that of blast cells from Peyer's patches, mesenteric lymph nodes, and thoracic duct lymph. The small IL were renewed very rapidly compared to small lymphocytes of peripheral lymphoid tissues, although small lymphocytes with life spans of several weeks were also present in the epithelial sheet. By the use of intestinal perfusion, *in vivo*, it was estimated that the loss of lymphocytes from intestinal villi into the lumen of the gut was negligible. It is concluded that the most probable kinetic model for the majority of IL is: B and T lymphoblasts invade the epithelium and undergo mitosis. B lymphoblasts give rise predominantly to plasma cells, and T lymphoblasts give rise to small lymphocytes, probably long-lived, that re-enter the circulation.

2484 KINETICS OF INTRAEPITHELIAL LYMPHOCYTES IN THE SMALL INTESTINE OF THYMUS-DEPRIVED MICE AND ANTIGEN-DEPRIVED MICE. (Eng.) Ropke, C.; Everett, N. B. (Anatomy Dept. A, Univ. Copenhagen, Copenhagen, Denmark). *Anat. Rec.* 185(1):101-108; 1976.

The kinetics of intra-epithelial lymphocytes (IL) of the small intestine was studied in various thymus-deprived mice and in antigen-deprived mice by the use of ^{3}H-thymidine injections and radioautography. In thymus-deprived mice--including adult thymectomized, thymectomized and irradiated, neonatally thymectomized, and nude mice--and in germfree mice, decreased numbers of IL were found. The radioautographic results indicated that the remaining IL populations included both newly formed and long-lived lymphoid cells in the same percentages as found in sham-operated controls and normal mice. It is concluded that although the presence of the thymus and the antigen content of the intestine is of importance to the maintenance of the numbers of cells in the lymphoid populations of the intestinal wall, the basic kinetics of these cell populations are preserved in deprived mice.

2485 INHIBITION OF MACROPHAGE MIGRATION BY NORMAL GUINEA PIG INTESTINAL SECRETIONS.

(Eng.) Gadol, N.; Waldman, R. H.; Clem, L. W. (Dept. Immunology, University of Florida, Gainesville, FL 32610). *Proc. Soc. Exp. Biol. Med.* 151(4):654-658; 1976.

Intestinal cultures from Hartley guinea pigs orally immunized with live and heat-killed *Vibrio cholera* organisms were tested to determine whether they could produce macrophage migration inhibiting factor (MIF) in response to *in vitro* stimulation with *Vibrio* antigens. Sections of the small intestine were cultured for 24 hr and the proteins from the culture fluid were concentrated and then fractionated by Sephadex G-100 column chromatography. Two peaks of MIF activity were found; one contained a protein with a molecular weight of 25,000-50,000, which was heat stable at 56 C (30 min), destroyed by boiling for 1 hr, and completely inhibited by epinephrine. The other peak contained proteins with molecular weights above 100,000, which were only 50% inactivated by boiling for 1 hr and were not significantly affected by epinephrine. The characteristics of the low molecular weight protein are similar to those of authentic MIF. The characteristics of the high molecular weight protein resemble those of endotoxin, which could be derived from the bacteria present in the gut. It is suggested that the MIF present in normal intestine secretions may be derived from: T-cells stimulated by bacterial antigens present in the gut, B-cells present in the gut, or rapidly dividing mucosal cells. All of these cells may contribute to the MIF present in the gut.

2486 THE EFFECT OF CHOLECYSTOKININ-PANCREOZYMIN ON CIRCULATING GASTRIN LEVELS IN MAN AND DOG.

(Eng.) Lanciault, G.; Ertan, A.; Adair, L. S.; Brooks, F. P. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *Am. J. Dig. Dis.* 21(1): 39-43; 1976.

The effect of endogenous and exogenous cholecystokinin-pancreozymin (CCK) on circulating gastrin levels was studied in 11 human subjects and in 3 mongrel dogs to explain the reason for the observed gastrin stimulation after exogenous CCK administration. In seven human subjects, endogenous CCK release was produced by perfusing the jejunum with a mixture of amino acids (MAA: isoleucine, 11.3 mM; leucine, 17.0 mM; lysine, 13.5 mM; methionine, 5.2 mM; phenylalanine, 6.7 mM; threonine, 10.7 mM; tryptophan, 1.4 mM; and valine, 13.0 mM) at a rate of 11.4 ml/min. The other four subjects received an i.v. infusion of 10% pure GIH-CCK at 0.125 Crick, Harper, and Raper (CHR) U/kg/min. Serum gastrin levels were determined by a double antibody radioimmunoassay (RIA) technique. When the circulating levels of serum gastrin were determined during MAA perfusion, the concentrations were not significantly different from basal levels. However, exogenous CCK produced a fourfold increase in the circulating levels of serum gastrin ($p<0.05$). In one patient who had received exogenous CCK, blood samples were taken for 330 min after the infusion of CCK was stopped; serum gastrin levels returned to basal values 270 min after the infusion was terminated. When GIH-CCK was given by i.v. infusion at 0.125 CHR U/kg/min to dogs for 120 min, serum gastrin levels increased significantly within 30 min. These levels returned to control levels within 15 min after the infusion was terminated. In contrast, the same rate of infusion with cholecystokinin octapeptide (CCK-OP) produced no significant alterations in circulating gastrin levels. Standard RIA dilution curves for GIH-CCK and CCK-OP were compared with human synthetic gastrin I. Although the slope for GIH-CCK was the same as for gastrin I, it required eight times more CCK. The CCK-OP slope was not parallel with the gastrin I; concentrations of 100 pg/ml could not be measured, indicating a lack of sensitivity of the RIA to CCK and demonstrating that the gastrinemic effect is not a cross-reaction between the CCK and the gastrin antibody used in the RIA. It is concluded that, because GIH-CCK is only 10% pure, and because it is known to contain other polypeptides (i.e., gastrin, gastrin inhibitory polypeptide, and possibly vasoactive polypeptide), the gastrinemic response of exogenous CCK is probably due to an impurity in the CCK preparation. Therefore, when studying the effects of CCK on the gastrointestinal tract only the pure CCK or the octapeptide should be used.

2487 EFFECT OF BILATERAL NEPHRECTOMY ON SERUM GASTRIN CONCENTRATION, GASTRIC HISTAMINE CONTENT, HISTIDINE DECARBOXYLASE ACTIVITY, AND ACID SECRETION IN THE RAT.

(Eng.) El Munshid, H. A.; Liedberg, G.; Rehfeld, J. F.; Sundler, F.; Larsson, L. I.; Hakanson, R. (Dept. Pharmacology, Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 11(1):87-91; 1976.

The effect of nephrectomy on gastric histamine content, histidine decarboxylase activity, acid secretion, and serum gastrin concentration was studied in 72 male Wistar rats. Nephrectomy caused increased basal acid output in only two of seven rats. In two rats, the acid output was greatly reduced. Nephrectomy abolished the stimulation of acid secretion produced in six rats by pentagastrin (1 mg/kg, s.c.) but it did not abolish that produced by histamine dihydrochloride (25 mg/kg, s.c.) in five rats. Following nephrectomy, the concentration of serum gastrin increased over 10-fold; in eight rats antrectomized 2 weeks before nephrectomy, the gastrin level was raised about 3-fold. There was an almost 20-fol increase in histidine decarboxylase activity following nephrectomy, in the rats with an intact stomach and a 5-fold increase in the antrectomized animals. Treatment with pentagastrin did not raise the enzyme activity (250 pmol CO_2/mg/hr ± 35, compared to 214 ± 10 in nephrectomized controls). In non-nephrectomized, sham-operated animals, pentagastrin raised the enzyme activity (21 ± 2.2, compared with 6.0 in controls). The gastric histamine concentration was reduced 25% by nephrectomy. Pentagastrin reduced the histamine content in sham-operated rats (from 60.4 μg ± 2.4 to 45.2 ± 3.0, 1 hr after operation), but it failed to do so after nephrectomy. In antrectomized rats, the concentration of histamine was much lower than in sham-operated animals. Nephrectomy did not reduce the gastric histamine content further. The results suggest that the kidney is important for metabolism and excretion, not only of gastrin, but of humoral antagonists of gastrin-induced acid secretion as well.

2488 EFFECTS OF PORTACAVAL ANASTOMOSIS ON GLUCOSE TOLERANCE IN THE DOG: EVIDENCE OF AN INTERACTION BETWEEN THE GUT AND THE LIVER IN ORAL GLUCOSE DISPOSAL. (Eng.) Lickley, H. L. A.; Chisholm, D. J.; Rabinovitch, A.; Wexler, M.; Dupre, J. (#937, Women's Coll. Hosp., 76 Grenville St., Toronto, Canada M5S 1B2). *Metabolism* 24(10):1157-1168; 1975.

The importance of the portal route of entry in the determination of glucose tolerance was assessed in healthy dogs. Continuous infusions of glucose (27 or 13.5 g/90 min) were administered in the duodenum (i.d.), or the portal vein (i.p.), or a peripheral vein (i.v.) in conscious dogs, intact dogs, or dogs with portacaval anastomoses. In intact animals, i.d. glucose tolerance was better than i.v. glucose tolerance, but i.p. glucose tolerance was not significantly different from i.v. glucose tolerance. Thus, the superiority of tolerance to i.d. glucose was not accounted for by relatively high levels of glucose in portal blood. Glucose tolerance (i.v.) was not significantly affected by portacaval anastomosis with ligation of the portal vein, but i.d. glucose tolerance was markedly impaired. Disproportionate impairment in tolerance to enterically administered glucose in dogs with portacaval shunts, and the similarity of i.p. and i.v. glucose tolerance in intact dogs, suggest that both the liver and the gut are important in determining oral glucose tolerance through mechanisms that have little or no effect on responses to parenterally administered glucose. The results also suggest that the hepatic contribution is not dependent upon portal venous perfusion of the liver, and that a humoral interaction between the gut and the liver is involved, which is not simply dependent upon endocrine responses of the pancreas.

DIAGNOSTIC PROCEDURES

2499 CYTOPATHOLOGY OF INTRA-HEPATIC BILE AS COMPONENT OF INTEGRATED PROCEDURE ("MINI-LAP") FOR HEPATOBILIARY DISORDERS. (Eng.) Wertlake, P. T.; Del Guercio, L. R. M. (Veterans Admin. Hosp., Sepulveda, CA 91343). *Acta Cytol.* 20(1):42-45; 1976.

The diagnostic effectiveness of cytologic study of bile as a convenient and inexpensive adjunct to an integrated procedure ("minilap") for hepatobiliary disorders was evaluated in 20 patients. Bile samples were obtained from intrahepatic bile ducts as a simple additional step in the performance of open transhepatic cholangiography. Six patients were determined to have adenocarcinoma; the tumors occurred in the head of the pancreas in four, in the ampulla of Vater in one, and in the biliary ducts in one. The presence of metastatic adenocarcinoma was demonstrated by bile cytology and liver biopsy in three of these patients. Metastatic adenocarcinoma was demonstrated in two patients by bile cytology, whereas the liver biopsies were negative. Primary adenocarcinoma of the head of the pancreas was demonstrated by pancreatic biopsy of one patient. Bile cytology was negative in this patient. The remaining 14 patients were free of cancer. This study indicates that cytologic evaluation of intrahepatic bile is a valuable adjunct to the minilap procedure for the resolution of puzzling cases of hepatobiliary disease.

2500 QUANTITATIVE MEASUREMENT OF LACTOSE ABSORPTION. (Eng.) Bond, J. H.; Levitt, M. D. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Gastroenterology* 70(6):1058-1062; 1976.

Lactose absorption was determined in four normal and in six lactase-deficient subjects by three indirect methods. These involved: (1) measurement of pulmonary hydrogen excretion, (2) pulmonary $^{14}CO_2$ excretion, and (3) stool ^{14}C excretion after ingestion of 12.5 g of 1-^{14}C-lactose and 4 g of polyethylene glycol (PEG). The results were compared with absorption determined directly from the ^{14}C:PEG ratio of multiple terminal ileal aspirates. The fraction of lactose not absorbed, as determined by ileal aspiration, was 0-8% in normals and 42-75% in milk-intolerant subjects. Whereas all three indirect methods were useful in qualitatively separating normal from deficient subjects, the quantity of lactose absorbed, as determined by H_2 excretion, correlated most closely with ileal measurements (r=0.94). Pulmonary $^{14}CO_2$ excretion for 24 hr after ^{14}C-lactose ingestion did not distinguish normal (17 ± 4% of ingested ^{14}C/24 hr) from lactase-deficient subjects (21.1 ± 3%). Likewise, stool ^{14}C:PEG ratios grossly underestimated malabsorption with less than one-fourth of the nonabsorbed ^{14}C appearing in the stool. This suggests that individual differences in susceptibility to diarrhea after milk ingestion by lactase-deficient subjects may be due to differences in the quantity of lactose not absorbed and/or differences in the rate of bacterial metabolism of lactose in the colon. Analysis of ileal fluid collected during passage of the lactose meal indicated that about two-thirds of the osmotic load entering the colon consists of endogenous electrolytes. Thus, the water load delivered to the colon is about three times the amount calculated to be osmotically held by the nonabsorbed sugar.

2501 RADIOIMMUNOASSAY OF BILE ACIDS IN SERUM. (Eng.) Demers, L. M.; Hepner, G. (M. S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Clin. Chem.* 22(5):602-606; 1976.

Highly specific radioimmunoassay procedures were developed for the determination of glycine conjugated bile acids in the serum of patients with liver disease. Antibodies to two primary bile acids, cholylglycine and chenodeoxycholylglycine, and to two secondary bile acids, sulfolithocholylglycine and deoxycholylglycine, were raised in New Zealand rabbits after the acids were covalently linked to albumin by use of the carbodiimide reaction. Tubes were prepared consisting of acid standards, radiolabeled bile acids, antisera, and patients' sera. The tubes were allowed to equilibrate and diluted normal rabbit serum, free of bile acids, was added to each tube. Antibody-bound and free bile acids were separated by ammonium sulfate; they were then centrifuged, decanted, and the radioactivity was determined. As little as 10 pmol of standard bile acid displaced significant amounts of tracer at an antibody titer binding 50% of labeled hormone. The standard curve range was set at 10-80 pmol. Recovery and parallelism studies were performed with each assay to validate the individual bile acid radioimmunassay. The clinical revelance of individual bile acids was estimated by determining the individual bile acids in the serum of patients with various states of hepatobiliary disease. It is concluded that the concentration of bile acids in serum is increased in various states of liver disease and its measurement appears to be an extremely sensitive indicator of liver function.

2502 THE VALUE OF THE FATTY ACID MEAL IN ORAL CHOLECYSTOGRAPHY. (Eng.) Laufer, I.; Gle hill, L. (McMaster Univ. Medical Center, Hamilton, Ontario, Canada L8S 4J9). *Radiology* 114(3):525-527; 1975.

The value of the fatty acid meal in oral cholecystography was estimated in 231 patients by comparing th radiological diagnoses on fluoroscopic spot films before and after fatty meals. Findings were abnormal in 84 patients. Only one case was diagnosed differently after the meal; a small solitary gallstone was not appreciated before the meal, although it was seen clearly on the post-fat film when the gallbladder was contracted and free of overlying colonic gas. In four other patients, the meal was useful in confirming a probable diagnosis. Three had adenomyomatosis, and in the fourth patien a solitary filling defect in the gallbladder did no move with changes in the patient's position. Howev the post-fat film showed the defect in a different position, indicating that it was a stone rather tha a polyp. It is suggested that fluoroscopic compression spot films be obtained first and that fatty meal be administered if indications still exist. Indications for using a fatty meal include overlying gas shadows, differentiation of a stone from a polyp, adenomyomatosis, distended gallbladder, and suspected common bile duct obstruction. It is estimated that less than 10% of patients should require a fatty meal.

2503 CORRELATION OF ENDOSCOPY AND DOUBLE-CONTRAST RADIOGRAPHY IN THE EARLY STAGES OF ULCERATIVE AND GRANULOMATOUS COLITIS. (Eng.) Laufer, I.; Mullens, J. E.; Hamilton, J. (McMaster Univ. Medical Center, Hamilton, Ontario, Canada L8S 4J9). *Radiology* 118(1):1-5; 1976.

The results of double-contrast radiographic examinations in 90 patients with inflammatory bowel disease were analyzed and compared with those of endoscopic studies during the early stages of disease. The importance of certain technical aspects of the double-contrast study is stressed: bowel cleansing, choice of barium preparation, and patient rotation. The earliest detectable abnormality on the double-contrast study for ulcerative colitis was a fine granular appearance of the mucosa. Superficial ulcers or erosions appeared as the disease progressed; endoscopically, these were seen as tiny bleeding points, and on double-contrast study, barium adhered to these ulcers, resulting in a stippled mucosal pattern. The early lesions of granulomatous colitis, which were seen endoscopically as multiple small, superficial ulcers with intervening normal mucosa, were readily detected by double-contrast study as tiny collections of barium, and in some cases they were surrounded by a radiolucent halo (due to edema). The radiological and endoscopic findings were in agreement in 95% of the cases. Because of the double-contrast study's value in detecting early disease and in clarifying the differential diagnosis in granulomatous colitis, it is suggested that colonoscopy not be performed in patients with inflammatory bowel disease.

2504 USE OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE DIAGNOSIS OF PANCREATIC FISTULA: A CASE REPORT AND REVIEW OF THE LITERATURE. (Eng.) Bohlman, T. W.; Katon, R. M.; Lee, T. G.; Eidemiller, L. R. (Univ. Oregon Health Sciences Center, 3181 S.W. Sam Jackson Park Rd., Portland, OR 97201). *Gastroenterology* 70(4):582-584; 1976.

The case report of a 43-yr-old man with pancreaticocolonic fistula is presented. The man presented with melena, hematochezia, and dizziness. Endoscopic retrograde cholangiopancreatography (ERCP) revealed the cause of the gastrointestinal bleeding; a fistulous tract was seen to pass inferiorly from the tail of the pancreatic duct to the region of the left colon. There was opacification of a cystic cavity and opacification of the colon in the splenic flexure region, establishing the diagnosis of a fistula. Abdominal exploration further revealed the presence of a cystic inflammatory mass applied to the posterior/inferior surface of the pancreas, the medial surfaces of the spleen, and the left side of the transverse colon. The colon was repaired, and caudal drainage of the fistulous tract and pancreatic duct, splenectomy, cholecystectomy, and removal of the tail of the pancreas were undertaken, with successful results. It is concluded that ERCP is a valuable tool for the pre-operative evaluation of patients who are suspected of having communication with the gastrointestinal tract.

2505 CHOLEDOCHAL CYST DEMONSTRATED BY DRIP INFUSION CHOLANGIOGRAPHY, REPORT OF SIX CASES IN ADULTS. (Eng.) Yamasaki, M. (Niigata Univ., Sch. Medicine, Niigata, Japan). *Acta Med. Biol.* 23(1):23-33; 1975.

The use of drip infusion cholecystocholangiography and tomography in the positive diagnosis of a choledochal cyst is discussed and illustrated in case studies of six adults. Oral cholecystographic study usually failed to demonstrate a gallbladder shadow when the cyst was large; intravenous or infusion cholangiography was necessary to demonstrate the condition. In the absence of jaundice, i.v. cholangiography was necessary to demonstrate the condition, and i.v. cholecystocholangiography usually provided adequate visualization of the biliary tree for diagnosis. The rate of positive diagnosis was increased by demonstrating the dilated common duct pre-operatively, following administration by the drip infusion method. In drip infusion cholecystocholangiography, the gallbladder and bile ducts were demonstrated simultaneously usually 90-120 min following the injection. The reliability of biliary tract opacification is more constant than with the usual injection technique, and there is a higher success rate of bile duct opacification in the presence of jaundice. The density of biliary tract opacification is greater than with the conventional technique, and there is the improved ability to visualize directly the dilated bile duct. There is a possibility of performing tomographic studies because of the simultaneous, long opacification of the components of the extrabiliary system. The superiority of this method using tomography or planigraphy is stressed.

2506 ENDOSCOPY-RELATED BACTEREMIA. INCIDENCE OF POSITIVE BLOOD CULTURES AFTER ENDOSCOPY OF UPPER GASTROINTESTINAL TRACT. (Eng.) Mellow, M. H.; Lewis, R. J. (Harlem Hosp. Center, 136th St. and Lenox Ave, New York, NY 10037). *Arch. Intern. Med.* 136(6):667-669; 1976.

The incidence of endoscopy-related bacteremia of the upper gastrointestinal tract was investigated in 100 patients, in a prospective study. Three patients showed positive blood cultures, after the endoscopy procedure. Cultures were made of samples from equipment and environment in the operating room. Bacillus species, *Micrococcus*, *Staphylococcus epidermidis*, and diphtheroids were most frequently cultured from the environment. There was also one case of *Enterobacter liquefaciens* and *Candida albicans* growth from the endoscope tip. It is concluded that although the incidence of postendoscopy positive blood cultures was low, a more vigorous approach to using clean equipment in clean surroundings is needed when dealing with a potentially susceptible host. It is suggested that "sterile" be substituted for "clean air" in these procedures.

2507 INTRAMURAL BARIUM IN ISCHEMIC COLITIS: A NEW RADIOGRAPHIC FINDING. (Eng.) Greves, J. H., III; Bohlman, T. W.; Frische, L. H.; Katon, R. M. (Univ. Oregon Medical Sch., 3181 Southwest Sam Jackson Park Road, Portland, OR 97201). *Am. J. Dig. Dis.* 21(3):257-262; 1976.

Two cases of ischemic colitis are presented, demonstrating a new radiographic finding of intramural dissection of barium. The differential diagnosis in these patients included idiopathic ulcerative colitis, granulomatous colitis, infectious colitis, diverticulitis, and ischemic colitis. Stool cultures from both patients were negative for enteric pathogens, and no amebae were seen in stool specimens or in mucosal biopsies. No diverticula were observed on barium enema or colonoscopy in either patient. The rectum and lower sigmoid were free of disease in both patients. Contrast studies of the colon revealed no abscesses, strictures, skip areas, fistulas, cobblestoning, or terminal ileal involvement. The involved segment in both cases was short and limited to the left colon, typical of ischemic colitis. The barium enema examinations, although not characteristic of ischemic colitis, did reveal dissection of barium into the wall of the colon. The presence of barium persisted 3 days following enema administration in one patient, and for 1 week, in the other patient. It is concluded that the persistence of intramural colonic barium in a patient presenting with rectal bleeding of unclear etiology or a nonspecific colitis should suggest the diagnosis of ischemic colitis, even if the more typical roentgenographic changes are lacking.

2508 THE EFFECT OF GLUCAGON ON BARIUM-ENEMA EXAMINATION. (Eng.) Meeroff, J. C.; Jorgens, J.; Isenberg, J. I. (Wadsworth Veterans Admin. Hosp., Los Angeles, CA). *Radiology* 115(1): 5-7; 1975.

Fifty barium enema studies with glucagon and 50 with a placebo were performed in 84 men to determine the effect of glucagon on colonic spasm, patient discomfort, and diagnostic quality. All patients received a low-residue diet for 2 days, followed by 59 ml of castor oil before the examination, and all were fasted overnight. Either glucagon (2 mg/2 ml) or placebo (2 ml) was injected i.m. in a randomized double-blind fashion, 10 min before beginning the enema. The patients who received glucagon showed a highly significant improvement ($p<0.001$); they had increased bowel relaxation, less discomfort, less spasm, and improved radiographic quality, as compared with the placebo group. The placebo group demonstrated a significant increase in mean pulse and mean diastolic blood pressure following the enema ($p<0.05$) but not in mean systolic blood pressure. The authors conclude that glucagon is effective in diminishing the prevalence of colonic spasm, improving radiographic quality, and decreasing patient discomfort during the barium enema examination.

2509 ULTRASONIC SCANNING OF PANCREATIC LESIONS: EFFICACY OF ULTRASONOGRAPHY IN PANCREATIC DISORDERS COMPARED TO ENDOSCOPIC RETROGRADE PANCREATOGRAPHY. (Ger.) Lutz, H.; Petzoldt, R.; Hofmann, K. P.; Rosch, W. (Medizinische Universitats-Klinik, Ultraschallabor, D-8520 Erlangen, West Germany). *Klin. Wochenschr.* 53(9):419-424; 1975.

The diagnostic efficacy of ultrasonography in pancreatic disorders was evaluated by comparing the results of this procedure with the results of endoscopic retrograde pancreatography in 140 patients. In 23 patients, retrograde cannulation of Vaters' papilla was unsuccessful due to a previous Billroth II resection. Examination of the pancreas with ultrasonography was not possible in 20 patients because of meteorism or severe adipositas. In 15 subjects, the sonographic findings were equivocal. Out of 105 ultrasonic findings, 3 were false-negative, and 5 were false-positive, whereas retrograde pancreatography resulted in 9 false-negative and 2 false-positive interpretations. In 50 out of 67 cases of pancreatic disorders diagnosed by ultrasonography, a further differentiation between malignant tumors and benign pseudotumors (pancreatitis or cyst) was possible. Ultrasonography was superior in the diagnosis of pancreatic cysts (23 of 27) as compared with retrograde pancreatography (12 of 27) since many cysts do not communicate with the ductal system. In comparison to the endoscopic method, ultrasonography is safer and less expensive. It is concluded that the two methods supplement each other so that a high diagnostic accuracy can be achieved (over 95%).

2510 MULTIPLE "BULL'S-EYE" LESIONS IN GASTRIC LYMPHOMA. (Eng.) Dunnick, N. R.; Harell, G. S.; Parker, B. R. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *Am. J. Roentgenol.* 126(5): 965-969; 1976.

Three cases of adolescent patients with multiple gastric target lesions and gastric lymphoma are reported. In addition, 119 cases were reviewed to determine whether multiple gastric target lesions are confined to adolescent patients or to patients with a particular subtype. All patients presented with abdominal pain, nausea, and vomiting. Each had a poorly differentiated or histiocytic lymphoma with disease at other sites. Two patients had lymphoma involving the small bowel as well as the stomach. One patient had multiple small bowel endoexcentric and polypoid intraluminal masses, and in another patient, multiple target lesions were present in the duodenum. The literature review revealed that multiple gastric lymphomatous target lesions are not confined to adolescent patients or to patients with a particular histologic subtype.

2511 EOSINOPHILIC GRANULOCYTES ON THE GASTROCYTOGRAM. (Eng.) Miczban, I. (Municipal Janos Hosp., Polyclinic Budapest, Hungary). *Acta Cytol.* 20(1):32-34; 1976.

The causes and significance of the eosinophilia observed in lavage gastrocytograms of 23 patients with various gastric diseases were examined. Eosinophilia was transitory in nine patients, and it was not found 2 weeks after the initial examination. In these patients the cells of the gastric mucosa were normal, but there was an increase in WBC, interstitial cells, plasmacytes, histiocytes, and macrophages. No eosinophilic granulocytes were observed in blood or sputum. In three patients, a significant and high grade allergic condition was present. Eosinophilic granulocytes were found in gastric juice aspirated from the empty stomach and in the lavage of one of these patients. The second allergic patient had a 10% concentration of eosinophilic granulocytes, while the third patient had 8-15% in the blood and 30% in the gastric smear. In two patients, the accumulation of eosinophilic granulocytes was accompanied by a polyp. The presence of eosinophilic granulocytes was associated with four cases of cancer; of the two in whom operation was possible, one showed scirrhus and the other showed polypoid carcinoma. Eosinophilia was associated with giardia lamblia, gastric ulcer, or gastric ulcer with eosinophilic gastritis in three other cases. The remaining patient was under prolonged gastrocytologic control and had atypical gastric epithelium (large clusters of surface mucosal cells and cytoplasmic vacuolization with goblet cell metaplasia). However, there were no neoplastic changes in the gastric epithelium of this patient. It is suggested that the presence of eosinophils in the gastrocytogram may accompany malignant changes.

2512 VASCULAR IMPRESSIONS OF THE GUT SECONDARY TO CHRONIC VASCULAR OCCLUSIVE DISEASE. (Eng.) Menuck, L.; Coel, M. (Dept. Radiology, Univ. California San Diego, San Diego, CA 92161). *Am. J. Roentgenol.* 126(5):970-973; 1976.

The cases of 12 patients with chronic vascular occlusion involving the gut are discussed. Arteriography revealed that of the eight patients who underwent upper gastrointestinal barium studies, five demonstrated definite contoural defects related to large collaterals. Three of these cases are presented. These patients had discrete extrinsic contoural defects along the medial aspect of the descending duodenum. The presence of contoural defects are useful in the differential diagnosis of vascular occlusion, particularly because of the often vague and nonspecific symptoms. It is concluded that visceral arteriography should be considered in patients whose radiographic examinations reveal these irregularities.

2513 GASTRIC ACID AND SERUM GASTRIN SECRETION BEFORE AND AFTER BYPASS OF THE SMALL INTESTINE FOR MORBID OBESITY. (Eng.) Coutsoftides, T.; Baranowski, J.; Himal, H. S. (Dept. Experimental Surgery, McGill Univ., Montreal, Canada). *Surg. Gynecol. Obstet.* 142(4):521-523; 1976.

Gastric acid output and serum gastrin were measured preoperatively and within 3 months postoperatively in six patients undergoing end-to-side jejuno-ileal bypass for morbid obesity. Meat extract stimulated acid output was higher in obese than in nine normal subjects. Following the bypass procedure, basal and meat extract stimulated acid output significantly decreased. Basal and meat extract stimulated serum gastrin levels did not change following bypass. These studies demonstrate that after a small intestinal bypass, acid output decreases. Gastrin plays no role in this change.

2514 DEMONSTRATION OF BLEEDING FROM MECKEL'S DIVERTICULUM BY MEANS OF SELECTIVE ARTERIOGRAPHY OF THE SUPERIOR MESENTERIC ARTERY. (Eng.) Perlberger, R. R. (Dept. Diagnostic Radiology, Academisch Ziekenhuis, Rotterdam, Netherlands). *Radiol. Clin.* 44(5):397-401; 1975.

The case of a 21-yr-old man with a bleeding Meckel's diverticulum is presented. The patient presented several episodes of rectal bleeding over a 3-yr period, but x-ray examinations of the stomach, duodenum, small intestine, and colon were normal. Angiography of the superior mesenteric artery revealed a wide and tortuous ileal branch, and there was a contrast leak in a major branch of one of the ileal distal arteries. It is suggested that arteriography be performed before other contrast medium studies in cases of lower gastrointestinal bleeding.

2515 ACTIVITIES OF ASPARTATE AND ALANINE AMINOTRANSFERASES AND ALKALINE PHOSPHATASE IN SERA OF HEALTHY SUBJECTS. (Eng.) Penttila, I. M.; Jokela, H. A.; Vitala, A. J.; Heikkinen, E.; Nummi, S.; Pystynen, P.; Saastamoinen, J. (Univ. Central Hosp., Kuopio, Finland). *Scand. J. Clin. Lab. Invest.* 35(3):275-284; 1975.

2516 QUANTITATION OF TUMOR VOLUMES AND RESPONSE TO THERAPY WITH ULTRASOUND B-SCANS. (Eng.) Tolbert, D. D.; Zagzebski, J. A.; Banjavic, R. A.; Wiley, A. L., Jr. (Univ. Wisconsin Hosp., Madison, WI 53706). *Radiology* 113(3):705-708; 1975.

2517 WHAT IS THE PLACE OF UPPER GASTROINTESTINAL FIBERENDOSCOPY IN GASTROENTEROLOGICAL DIAGNOSIS IN 1974? (Fre.) Guerre, J.; Christoforov, B.; Duflo, B.; Chopita, N.; Pequignot, H. (Hopital Cochin, 27, rue Fg Saint-Jacques, 75674 Paris Cedex 14, France). *Entretiens Bichat Med.* 1974: 81-84.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2554 EFFECT OF PERFUSION OF BILE SALTS SOLUTIONS INTO THE OESOPHAGUS OF HIATAL HERNIA PATIENTS AND CONTROLS. (Eng.) Bachir, G. S.; Collis, J. L. (Birmingham Medical Sch., Birmingham, England). *Thorax* 31(3):271-277; 1976.

The esophageal mucosa of 54 hiatal hernia patients was tested to determine sensitivity to acid and solutions of the bile salt conjugates separately, and in mixtures, in normal saline and acid. Patients were divided into three groups (18 in each group): group I, symptomatic hiatal hernia patients; group II, hiatal hernia patients with peptic stricture; and group III, normal controls. Each esophagus was perfused at a rate of 45-65 drops/min over 25 min with six solutions: normal saline, N/10 HCl, taurine conjugates of bile salts in N/10 HCl, glycine conjugates of bile salts in normal saline, and taurine and glycine conjugates in a ratio of 1:2 in normal saline. Acidified solutions of taurine conjugates were more irritating than acid alone. With a 2 mM/l solution of taurine conjugates in acid, symptoms were produced even in controls. With a 1 mM/l solution of the same conjugates, the majority of controls felt slight heartburn or nothing. The results indicate that perfusion of acidified solutions into the esophagus can be used as a test solution for esophagitis.

2555 THE ASSOCIATION AND EMBRYOGENESIS OF TRACHEO-OESOPHAGEAL AND ANORECTAL ANOMALIES. (Eng.) Piekarski, D. H.; Stephens, F. D. (Royal Children's Hosp., Melbourne 3052, Australia). *Prog. Pediatr. Surg.* 9:63-76; 1976.

Thirty-one patients with combined esophageal and anorectal anomalies comprising 10% of 328 consecutive foregut malformations and 246 anorectal deformities were studied. Twenty-three of the combined group had at least one other associated anomaly. Twenty-three of this series also exhibited at least three of the VATER defects. There was a very high incidence of associated vertebral, urological, and musculoskeletal anomalies. This high incidence of additional lesions is presumably a reflection of generalized early damage to the mesenchymal tissues at the fourth week of gestation. Similar embryological mechanisms may take place and be affected similarly in both foregut and hindgut systems; the concept of a two-component septum dividing the foregut and hindgut is proposed to explain the formation and malformations in these regions. Disturbances of alignment, direction, and extent of these component septa induced by hyperflexion of the foregut and hindgut, and intrinsic septal defects presumably account for most of the malformations. Hyperflexion may also account for malformations of other systems and for the high incidence of associated anomalies in the 31 patients with esophagorectal deformities.

2556 ESOPHAGEAL MONILIASIS: A REVIEW OF COMMON AND LESS FREQUENT CHARACTERISTICS. (Eng.) Lewicki, A. M.; Moore, J. P. (George Washington Univ. Medical Center, Washington, DC 20037). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):218-225; 1975.

The clinical and roentgenographic characteristics of esophageal moniliasis are reviewed. Invasion of the esophagus by *Candida albicans* probably occurs more frequently than the reported cases suggest. The disease usually occurs following immunosuppression, but it may occur after antibiotic therapy. In the latter case, it is postulated that the fungi overgrow because they do not have to compete for nutritive substances with the normal bacterial flora that are removed by the antibiotics. Clinical symptoms include sudden onset of severe pain and dysphagia; recovery may occur after 2 days of treatment, or death due to dissemination may result. When the fungi are found in the mycelial form rather than exclusively as yeasts (the latter are found in the mouth and feces of healthy individuals), invasion can be assumed. Roentgenographically, impaired motility is much more prominent than is disordered motility or spasm. The degree of impaired motility directly reflects the severity of esophageal involvement and is usually worse in the distal portion of the esophagus. Esophageal moniliasis probably results from the spread of *Candida albicans* from the oral cavity to the esophagus. Esophagoscopy reveals that the cervical esophagus is involved from the level of the cricopharyngeus, but involvement at the cervical level or in the hypopharynx has not been described roentgenographically. As the disease progresses, compromise of the diameter of the esophageal lumen may occur from both edema of the mucosa and the presence of an overlying pseudomembrane. Morphological characteristics of the disease include a cobblestone epithelium, and later, erosions and ulcerations. Occasionally an asymmetrical, abrupt stenosis due to monilial disease may simulate an infiltrating neoplasm. The most important differential point for distinguishing varices and carcinoma from moniliasis is the striking variability of roentgen findings over a short time period. Antifungal agents are effective in treating moniliasis.

STOMACH

2585 MAST CELLS OF THE HUMAN STOMACH. (Eng.) Steer, H. W. (Radcliffe Infirmary, Oxford, England). *J. Anat.* 121(2):385-397; 1976.

Morphological aspects of mast cell function were studied using biopsy material obtained from four different sites (prepyloric, incisura angularis, high on the lesser curve, and high on the greater curve) of the stomach of 5 normal subjects and 30 patients with gastric ulceration. Light microscopy revealed mast cells in all regions. The cells, stained metachromatically, showed granules with characteristic ultrastructural features, did not possess a basement lamina, and were normally found in connective tissue. Differences were noted between the subepithelial mast cells and the intraepithelial mast cells and a gradation was noted between them. Evidence of degranulation was found in the subepithelial mast cells, but not in the epithelial mast cells. Vacuolation occurred mainly in the epithelial mast cells, but it was present to a limited extent in the subepithelial cells. Subepithelial mast cells contained both orthochromatically and metachromatically stained granules. No granules consisting entirely of a lamellar substructure were noted in epithelial mast cells. Findings indicate that only the lamellar type of granule undergoes degranulation. Metachromatic granules were seen mainly in the subepithelial mast cells using methylene blue-Azur II staining, whereas the metachromasia of the epithelial mast cells was demonstrated principally in the vacuoles. The disappearance of metachromatic granules from the mast cells, which migrated into the gastric epithelium coincided with the disappearance of those granules, which were entirely lamellar in structure. It is considered that the lamellar granules represent the metachromatic granules seen with the light microscope. When granule disintegration with vacuolation becomes complete, the nucleus becomes uniformly electron-dense and the mast cell is shed into the gastric lumen.

2586 LDH ISOENZYME PATTERN OF UNINVOLVED GASTRIC MUCOSA OF PATIENTS WITH GASTRIC CARCINOMA AND BENIGN GASTRIC DISEASE. (Eng.) Woollams, R.; Barratt, P. J.; Orwell, R. L.; Piper, D. W. (Dept. Medicine, Univ. Sydney, Australia). *Digestion* 14(1):20-28; 1976.

The lactate dehydrogenase (LDH) isoenzyme pattern of uninvolved gastric mucosa of patients with gastric cancer, gastric ulcer, and duodenal ulcer was studied and compared. Effects of gastritis and intestinal metaplasia on the LDH isoenzyme pattern re also assessed. The study showed that the M/H tio (M and H subunits) and the (IV + V)/(I + II) d V/I isoenzyme ratios were higher in antral mucosa an in body mucosa in gastric and duodenal ulcer tients as well as in gastric carcinoma patients. e gastric carcinoma group differed significantly om both the gastric and duodenal ulcer groups in e M/H ratio, isoenzyme (IV + V)/(I + II) ratio, and oenzyme V/I ratio of uninvolved body mucosa. Values r the two peptic ulcer groups were similar. Rearding antral mucosa, the gastric cancer group difered from both ulcer group patients with respect to he M/H ratio. The gastric ulcer and gastric cancer roups differed in their (IV + V)/(I + II) and V/I soenzyme ratios, while the duodenal ulcer and gastric ancer groups were similar with regard to these atios. Thus, the rise in M/H ratio associated with astritis was confirmed, but intestinal metaplasia lone did not significantly alter this ratio. Uninolved antral and body mucosa of gastric cancer paients differed from similar mucosa of ulcer patients, he mucosa of cancer patients resembling that usually ound in cancer tissue. These observations are conistent with the concept that the tissue from which he cancer arose may possess a premalignant biochemical lesion.

2587 SUTURE GRANULOMAS SIMULATING TUMORS: A PREVENTABLE POSTGASTRECTOMY COMPLICATION. (Eng.) Gueller, R.; Shapiro, H. A.; Nelson, J. A.; Bush, R. (Veterans Admin. Hosp., San Francisco, CA). *Am. J. Dig. Dis.* 21(3):223-228; 1976.

Four cases of patients with suture granulomas are presented. The patients underwent some form of gastric surgery (gastrojejunostomy, oversewing of perforated pyloroduodenal ulcer, 50% Hoffmeister gastric resection, or antrectomy with Billroth I anastomosis and truncal vagotomy), which involved the use of silk sutures. The patients' symptoms were explained by associated lesions, such as adhesions, suture-line ulcers, erosions, or abscesses--conditions that appeared to be related to nonabsorbable suture material. In all four patients, the differential diagnosis was difficult on the basis of their upper gastrointestinal series, and the granuloma was precisely diagnosed by surgical biopsy. It is suggested that a new absorbable suture material, polyglycolic acid, may eliminate this problem.

2588 INDUCTION OF PYLORIC HYPERTROPHY BY PENTAGASTRIN: AN ANIMAL MODEL FOR INFANTILE HYPERTROPHIC PYLORIC STENOSIS. (Eng.) Dodge, J. A.; Karim, A. A. (Univ. Hosp. Wales, Heath Park, Cardiff, U.K.). *Gut* 17(4):280-284; 1976.

Twenty pregnant bitches and/or their pups were given pentagastrin in depot form to produce an animal model for infantile hypertrophic pyloric stenosis. Two depot forms of pentagastrin were prepared. In one, pentagastrin powder was suspended in an 8% or 10% mixture of beeswax in arachis oil (8 mg pentagastrin/ml). The second preparation used a base of 0.5% phenol and 16% gelatin (8 mg pentagastrin/ml). Fifty-six pups produced by 14 bitches were given 2-4 mg pentagastrin (and in one case 20 mg) twice daily for 1-85 days before term; they were then available for postmortem examination. Sixteen of these pups had pyloric hypertrophy. Nine of the 56 pups had ulcers in the prepyloric region, pyloric canal, or duodenum at necropsy, and perforation occurred in three instances. Within individual litters, some pups had pyloric hypertrophy, while the remainder were normal. Eight additional bitches were similarly treated for 5-49 days, and their 35 pups were given 0.5 to 4 mg of pentagastrin twice daily at birth; the duration of treatment was from 1 to 30 days. Nine pups had pyloric hypertrophy at necropsy, and five had ulcers. In 6 bitches and their 29 offspring, no treatment was given, and none showed any abnormalities on postmortem examination. Similar results were obtained in 4 bitches and their 18 offspring which received injections of beeswax or gelatin without pentagastrin. The histological features of the pylorus in pups showing hypertrophy closely resembled those of the human infant with pyloric stenosis. The circular muscle was hypertrophic. Ganglion cells in the myenteric plexus showed changes in size and configuration compared with controls, and occasional vacuolation was present. Submucosal ganglion cells were absent at the pyloroduodenal junction. The control groups differed significantly ($p<0.01$) from the first two treatment groups with respect to incidence of both pyloric hypertrophy and ulceration. The fact that some pups showed no abnormalities, while others in the same litter showed pyloric hypertrophy suggests that individual inherent susceptibilities are an important determinant of the response; this is similar to the situation in human infantile hypertrophic pyloric stenosis, where genetic and environmental factors apparently interact. In spite of the inconsistency of response, transplacental pentagastrin stimulation of the canine fetus appears to be a valid animal model for infantile pyloric stenosis.

2589 EFFECT OF VAGOTOMY ON THE GASTRIC SECRETORY RESPONSE TO INTRADUODENAL OSMOTIC AGENTS IN MAN. (Eng.) Ward, A. S. (Sheffield Royal Infirmary, Sheffield, England). *Gut* 17(1):48-53; 1976.

The effect of intraduodenal infusion of hypertonic saline and glucose on pentagastrin-stimulated gastric secretion was investigated in 35 normal subjects, 32 duodenal ulcer patients, and 32 patients after truncal vagotomy and pyloroplasty. Gastric secretion was stimulated by a continuous i.v. infusion of pentagastrin (6 μg/kg/hr in normal subjects and pre-operative patients, 9 μg/kg/hr in vagotomized subjects). A significant gastric inhibitory response occurred after 0.51 M saline in 7 of 12 normal subjects tested and in 9 of 12 duodenal ulcer patients ($p<0.01$ and $p<0.001$, resp., resp.). Inhibition of acid output occurred in 11 of 12 normal subjects and in all of 12 tested ulcer patients after 1.03 M glucose infusion ($p<0.001$). Acid output was unchanged in all of 10 vagotomized patients with 1.03 M glucose infusion and in 8 of 10 vagotomized patients with hypertonic saline. Inhibition occurred in all of five normal and in all of four ulcer patients with 2.75 M glucose infusion, and significant inhibition was also seen in four of six vagotomized patients ($p<0.05$). The results suggest that the inhibitory effect of glucose and hypertonic saline depends, at least partially, on a vagal reflex. Since the response to a very high glucose concentration persisted after vagotomy, a humoral mechanism may be involved.

Peptic Ulcers

2619 ELECTROPHORETIC ANALYSIS OF ACID PROTEOLYTIC ZYMOGENS IN MUCOSA SURROUNDING GASTRIC ULCER. (Eng.) Ishimori, A.; Kawamura, T.; Sakurada, H.; Shirane, A.; Yamagata, S.; Miura, Y.; Tsuda, K.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(4):349-354; 1976.

Acid proteolytic zymogens contained in biopsy specimens obtained from the area surrounding peptic ulcer of the stomach of three patients were analyzed by agar gel electrophoresis and were compared with the histopathological findings. The specimens obtained from the base of ulcer contained only slow moving protease (SMP), while mucosa located near the margin of ulcer showed the pyloric mucosal type of electrophoretic pattern. Increase in distance between the margin of ulcer and the site of biopsy changed the electrophoretic pattern of specimens to the fundic mucosal type. The electrophoretic findings of acid proteolytic zymogens were correlated closely to histological findings, and these changes were found to distribute in a patchy form around ulcer. Endoscopically healed scar was covered with regenerated epithelium containing parietal and chief cells; the electrophoretic pattern of acid proteolytic zymogens was of the fundic mucosal type. It is suggested that since atrophic changes of gastric mucosa around ulcer are known to remain relatively unchanged after healing, its clinical significance may be limited.

2620 THE VAGUS AND GASTRIN COMPONENTS IN PERIPHERAL BLOOD. (Eng.) Stadil, F.; Malmstrom, J.; Christensen, K. C. (Rigshospitalet, 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):77-80; 1976.

The role of the vagus in the pattern of peripheral blood gastrins was studied in 16 patients with duodenal ulcer before and 2 weeks after selective gastric vagotomy (8 patients) or truncal vagotomy (8 patients). In two normal subjects, vagal activity was stimulated by an i.v. insulin injection (0.2 IU/kg); one subject was also given an i.m. injection of atropine sulfate (30 μg/kg) 20 min prior to insulin. Blood was drawn from an indwelling cubital cannula at 0, 30, 45, and 60 min in the selective gastric vagotomy group and at 0, 10, 15, and 25 min in the truncal vagotomy group; blood was drawn in the normal subjects throughout a 240-min period. Gastrins were fractionated by gel chromatography. Serum gastrin was almost exclusively made up of gastrin component II (which is gastrin 34-like) and gastrin component III (gastrin 17-like). Both components rose after feeding, but the major increase was in component III. Although fasting levels and total responses of gastrin to food were higher postoperatively, the pattern of the gastrin components after the two operations remained unchanged. Total concentrations of gastrin increased to a peak level 45 min after insulin injection, whether or not the injection was preceded by atropine; this was due to an increase in component III and, to a lesser extent, to component II. These studies indicate that the release of gastrins is not reduced by vagotomy, and that there is no gastrin component that is selectively released into the circulation by vagal activity. Because earlier findings have shown that hypoglycemic gastrin response is of antral origin, the results suggest that the antrum is a source of both gastrin components II and III.

2621 SIMPLE CLINICAL METHOD OF MEASURING GASTRIC EMPTYING OF SOLID MEALS. (Eng.)

Ostick, D. G.; Green, G.; Howe, K.; Dymock, I. W.; Cowley, D. J. (Univ. Hosp. South Manchester, West Didsbury, Manchester M20 8LR, England). *Gut* 17(3): 189-191; 1976.

The use of a single fixed scintillation detector for the measurement of gastric emptying of solid meals was evaluated in 20 healthy subjects and in 10 patients with duodenal ulcer. The results were compared with those obtained simultaneously by a gamma camera. The mean half emptying time of the volunteers was 49.3 min with the gamma camera and 48.2 min with the scintillation detector. The rates and patterns of gastric emptying recorded by the two methods correlated well in both healthy volunteers (mean range=0.95) and in patients with ulcer (mean range= 0.89). It is concluded that scintillation detector provides a reliable and inexpensive method for measurement of gastric emptying of solid meals.

2622 GASTRIC AND DUODENAL ULCERS IN THE SAME PATIENT.

(Eng.) Bonnevie, O. (Gentofte Univ. Hosp., DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 10(6):657-664; 1975.

An epidemiologic investigation of new cases of gastric and/or duodenal ulcer was conducted in 1,905 patients to determine the probability of developing a second ulcer. Gastric and duodenal ulcer were diagnosed on the basis of radiologic examinations. In 1,475 of the patients, a solitary duodenal ulcer occurred; in 350 a solitary gastric ulcer was diagnosed, while 80 patients presented with both forms of ulcer at the first positive radiologic examination. In patients with a gastric ulcer, the cumulated 6-yr probability of developing secondary ulcers was 8.8%, while the corresponding risk of secondary ulcer in patients with duodenal ulcer was 3.7%. The probability of developing secondary ulcers was the same in men and women, and was independent of the site and nature of the morphologic changes in the stomach and duodenum. Among patients with gastric ulcer, younger patients seemed particularly apt to develop secondary ulcers. This was not the case in patients with duodenal ulcer. The total probability of having both types of ulcers was 12%. The data indicate that gastric ulcer precedes duodenal ulcer more frequently than the reverse situation.

2623 MUCOSAL CHANGES IN GASTRIC ULCERATION AND THEIR RESPONSE TO CARBENOXOLONE SODIUM.

(Eng.) Steer, H. W.; Colin-Jones, D. G. (Radcliffe Infirmary, Oxford, England). *Gut* 16(8):590-597; 1975.

The gastric epithelium of 47 patients with benign gastric ulceration and of 6 normal subjects was studied to examine the relation between the activity of gastritis, bacteria, and gastric ulceration, and to evaluate the effect of carbenoxolone sodium treatment on the gastric mucosa in gastric ulceration. The concentrations of intraepithelial lymphocytes and polymorphonuclear leukocytes in lesser curve and prepyloric gastric ulcers were compared. There was a statistically significant reduction in the total number of intra-epithelial polymorphonuclear leukocytes before and after successful treatment with carbenoxolone sodium in 12 patients ($p< 0.05$). There was also a statistically significant decrease in the quantity of intra-epithelial lymphocytes in those patients with lesser curve gastric ulcers who were successfully treated with carbenoxolone sodium ($p<0.05$), whereas there was a significant increase in patients with prepyloric gastric ulcers treated successfully ($p<0.05$) and in patients whose treatment failed. The value of counts of migrating WBC as a method of objectively assessing the effect of healing drugs upon the gastric mucosa is discussed. *Pseudomonas aeruginosa* was found in many specimens from the ulcer patients, and this was not a contaminant. Carbenoxolone appeared to increase the amount of mucous but it had little effect upon the number of bacteria found. The data suggest that *P. aeruginosa* may be an etiologic factor in gastric ulceration.

2624 INHIBITION OF BASAL AND STIMULATED GASTRIC H^+ AND PEPSIN SECRETION IN DUODENAL ULCER PATIENTS BY METIAMIDE, AN H-2 HISTAMINE ANTAGONIST.

(Eng.) Bajaj, S. C.; Hirschowitz, B. I. (Dept. Medicine, Univ. Alabama, Birmingham, AL 35294). *Am. J. Dig. Dis.* 21(7):557-562; 1976.

The effects of metiamide on basal, histamine, and insulin-hypoglycemia-stimulated gastric H^+ and pepsin secretion were investigated in 23 studies of

6 duodenal ulcer patients. Metiamide was given .o. in one dose of 200 mg in the basal state in 4, uring histamine infusion in 11, and before insulin ypoglycemia stimulation in 8. In the latter eight atients, insulin was given at another time without etiamide. In 17 studies, acid secretion was supressed by metiamide--up to 75% in the basal state, 3% after histamine, and 80% after insulin. Pepsin ecretion was reduced to the same extent as H^+ in he histamine studies but not in the basal (57%) or insulin (44%) studies, so that in the latter, epsin/acid ratios were threefold greater than in ontrols. Blood levels of metiamide were measured n 17 studies. In 10 out of 11 who showed inhibiion of 40% or more, peak blood levels of metiamide ere 0.45-1.25 μg/ml. In five of six who did not how inhibition, blood levels were 0.05-0.04 μg/ml; in the sixth it was 0.8 μg/ml. Therefore, a critical blood level for suppression of basal or stimulated secretion appears to be approximately 0.45 μg/ml. The effectiveness of a small single dose of metiamide for inhibiting basal and stimulated secretion in duodenal ulcer patients suggests its use in the treatment of peptic ulcers.

2625 THE EFFECT OF VARIOUS FORMS OF MILK ON GASTRIC ACID SECRETION. STUDIES IN PATIENTS WITH DUODENAL ULCER AND NORMAL SUBJECTS. (Eng.) Ippoliti, A. F.; Maxwell, V.; Isenberg, J. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Ann. Intern. Med.* 84(3):286-289; 1976.

The effect of various forms of milk and 0.15 M NaCl (control) on gastric acid secretion was studied in five patients with duodenal ulcer during a period of remission and in five normal subjects. Whole, low-fat, and nonfat milk (240 ml) each produced a significant ($p<0.05$) increase in mean gastric acid secretion in both groups. The NaCl did not increase gastric acid secretion above the basal level. Low calcium milk (240 ml) produced a significant ($p<0.05$) increase in mean acid secretion in the patients with duodenal ulcer, but not in the normal subjects. The acid secretory responses to milk were equivalent to those produced by a 300 ml 10% peptone meal and were approximately 20-35% of maximal betazole- or pentagastrin-stimulated acid output. There were no significant differences ($p>0.05$) between patients with duodenal ulcer and normal subjects, in response to whole, low fat, and nonfat milk expressed as a percentage of their maximal acid output. Because milk contains both protein and calcium, which are stimulants of gastric acid secretion, there is reason to question its frequent ingestion by patients with peptic ulcer.

2626 PARIETAL CELL VAGOTOMY WITHOUT DRAINAGE FOR TREATMENT OF DUODENAL ULCER: A TWO-TO THREE-YEAR FOLLOW-UP REPORT. (Eng.) Jordan, P. H., Jr. (1200 Moursund Ave., Houston, TX 77025). *Arch. Surg.* 111(4):370-376; 1976.

A 2- to 3-yr followup study was undertaken in 35 patients who underwent parietal cell vagotomy (PCV) without drainage. During the study, three patients died from causes unrelated to duodenal ulcer. Thirty-one of the remaining patients were followed up for 2 yr; 23 were studied after 3 yr. At the end of 2 yr, the mean basal acid output and peak hourly basal secretion rate were 43% and 47% less than the preoperative values, resp. The number of patients with a negative insulin test result postoperatively fell from 64% of patients tested at 2 months to 44% at 2 yr. The number of patients with an early positive insulin test result rose from 13% at 2 months to 28% at 2 yr after operation. There were two recurrent duodenal ulcers; one required reoperation. A gastric ulcer developed in one patient who was taking massive doses of aspirin (15 tablets/day), but the ulcer healed after aspirin withdrawal. One patient required operation for pyloric obstruction. Both dumping and diarrhea were reported by 7% of patients. These results suggest that PCV without drainage is an acceptable procedure for treatment of duodenal ulcer.

SMALL INTESTINE

2660 THE APPEARANCE OF THE SMALL BOWEL MUCOSA IN OLD AGE. (Eng.) Webster, S. G. P.; Leeming, J. T. (Univ. Hosp. South Manchester, Manchester M20 8LR, England). *Age Ageing* 4:168-174; 1975.

Normal necropsy specimens of jejunal mucosa from 32 young subjects (13-59 yr) were compared histologically with specimens from the jejunums of 39 geriatric patients. Nineteen specimens from the young subjects showed predominantly finger-shaped villi (i.e., cylindrical with a round cross-section). Less than 50% of the total villi were "narrow leaves" or 2-5 times as long as wide; these were designated as group 1. Ten specimens showed predominantly narrow leaf-shaped villi; less than 50% were finger-shaped (group 2). The remaining three specimens showed predominantly leaf-shaped villi, but some broad forms or ridges were present (group 3). Among the geriatric patients, 20 had group 1 morphology, 11 had group 2, and 6 had group 3; the remaining two patients had villi possessing at least two angulations of greater than 90 degrees (convoluted villi). In 16 geriatric patients, the mean villous height was 371 μm, villous width was 121 μm; mucosal thickness was 143 μm, and epithelial cell height was 33.6 μm. These studies indicate that there are structural differences between the proximal jejunal mucosa of elderly subjects and younger controls. Previous studies showed that the weighted mean villous height for 160 jejunal biopsies was significantly greater ($p<0.02$) than that for these geriatric patients. There is also evidence from these studies that geriatric patients have broader villi than younger patients. As the absorption of many substances is dependent upon the surface area available, these changes in the elderly may account for small bowel functional impairment.

2661 STUDIES OF ULTRAMICROSTRUCTURE IN RELATION TO DISACCHARIDASE ACTIVITY IN THE JEJUNAL MUCOSA. (Eng.) Yoshida, Y.; Sasaki, G.; Goto, S.; Yanagiya, S.; Nakasato, N.; Takashina, K.; Ito, A.; Matsunaga, F. (Hirosaki Univ. Sch. Medicine, Zaifu-cho 5, Hirosaki, 036 Japan). *Gastroenterol. Jpn.* 10(2):141-145; 1975.

The ultrastructural changes of the jejunal mucosa were compared to changes in disaccharidase activity in the jejunal mucosa of Wistar rats, in 9 normal human subjects, and in 50 patients with gastrointestinal diseases or diabetes. Jejunal biopsies were obtained from a point approximately 20 cm distal to the ligament of Treitz, using either the Tohoku University biopsy capsule or Rubin's multipurpose biopsy tube. Biopsies were obtained from 16 patients following gastric resection, from 14 patients with gastric ulcer, from 5 with ulcerative colitis, from 2 with irritable colon, from 7 with hepatic disease, and from 6 with diabetes mellitus. A comparative light microscopic study showed no difference in the histology of the villi or the lamina propria mucosa of the nine controls and the patients. Electron microscopic studies revealed that patients with higher microvilli had a correspondingly higher lactase activity ($p<0.01$). The height of the microvilli was not correlated with the activities of maltase and sucrase ($p>0.05$). In rats, which were fed a 25% lactose diet (4 g/day/rat) for 6 weeks, a similar relation was found; lactase activity increased from 6.8 U to 12.8 ± 2.4 U, while the height of the microvilli increased from 1.82 U to 1.94 U. No significant increase was seen in maltase and sucrase. In rats which were fed for 4 weeks on a low calorie diet (controls, approximately 70 calories/day/rat), the lactase activity of the jejunal mucosa increased from 6.8 U to 9.3 ± 3.1 U, while the height was raised from 1.82 U to 2.09 U. Controls, which were fed a commercial diet, showed no change in enzyme activity or microvilli height when sacrificed after 6 weeks of feeding. It is concluded that a decrease in the height of the villi is the initial change in diffuse intestinal diseases, and that this causes lactase deficiency in patients with gastrointestinal disease.

2662 ACRODERMATITIS ENTEROPATHICA: RECENT FINDINGS CONCERNING CLINICAL FEATURES, PATHOGENESIS, DIAGNOSIS AND THERAPY.

(Eng.) Braun, O. H.; Heilmann, K.; Pauli, W.; Rossner, J. A.; Bergmann, K. E. (Kinderklinik des Stadtischen Krankenhauses, Postfach 1680, D-7530 Pforzheim, W. Germany). *Eur. J. Pediatr.* 121(4):247-261; 1976.

Serum zinc and fatty acid levels were studied in two siblings (a boy and girl, aged 10 and 6 weeks, resp.) with acrodermatitis enteropathica (AE). Their case reports and histological and ultrastructural findings are presented. The family was unremarkable, except for consanguinity five generations previously. The clinical symptoms of the two patients conformed to the known features of AE, the gastrointestinal involvement losing its significance with increasing age. In a stage of exacerbation in the boy, the serum level of oleic acid (18:1) was lowered and of linoleic (18:2) acid was slightly increased, while that of arachidonic acid was decreased. In both patients, the serum zinc levels were significantly lowered. Under substitution with $ZnSO_4$ (220 or 110 mg/day) the clinical condition improved, and the serum zinc levels returned to normal. Histologically, the small bowel mucosa was practically normal. Ultrastructural examination of jejunal biopsies revealed rather unspecific changes in the enterocytes in the form of numerous multivesicular bodies. The Paneth cells sometimes contained irregularly formed inhomogeneous structures within their cytoplasm, which were assumed to be inclusion bodies. In addition, the secretory granules varied in size and displayed a granular heteromorphic matrix. Frequently, they were confluent and formed giant granules. It is concluded that since AE is probably caused by a lack of zinc, successful treatment with zinc administration is possible, thus avoiding the toxic side effects of oxyquinoline. Further investigations must be made to determine whether the ultrastructural changes in the Paneth cells are specific for AE and are perhaps caused by the defect in the resorption of zinc.

2663 CONTAMINATION OF THE SMALL INTESTINE BY ENTEROTOXIGENIC COLIFORM BACTERIA AMONG THE RURAL POPULATION OF HAITI.

(Eng.) Klipstein, F. A.; Short, H. B.; Engert, R. F.; Jean, L.; Weaver, G. A. (Univ. Rochester Medical Center, 601 Elmwood Ave., Rochester, NY 14642). *Gastroenterology* 70(6): 1035-1041; 1976.

The bacterial population within the proximal small intestine was examined for the presence of coliform bacteria in 15 Haitians with tropical sprue or other milder gastrointestinal abnormalities. Coliform bacteria were isolated by either aerobic or anaerobic culture techniques from aspirates of the proximal small intestine of 4 of 5 Haitians with tropical sprue but not from any of 10 well nourished patients with milder gastrointestinal complaints. *Klebsiella pneumoniae* and *Klebsiella ozaenae* were cultured from the jejunal aspirates of two sprue patients and *Escherichia coli* from the other two. Fifteen colonies of coliform bacteria cultured from each aspirate were specifically identified by their biotype. In three instances, every colony in each aspirate was the same; in the fourth aspirate, two biotypes of *E. coli* were present, one of which grew under both aerobic and anaerobic culture conditions and another of which grew only under anaerobic conditions on initial isolation. A randomly selected strain of each of the five coliform biotypes isolated was examined for enterotoxigenicity by determining the effect of variously prepared cell-free preparations on water transport in the rat jejunum using standard marker perfusion techniques. Every strain tested was toxigenic; one produced only a heat-stable toxin, one produced a heat-labile toxin only, and three elaborated both forms of enterotoxin. These observations indicate that most Haitians with tropical sprue have colonization of the proximal small intestine by a specific strain of enterotoxigenic coliform bacteria, but this is not the case among Haitians who have milder intestinal abnormalities.

2664 IgA DEFICIENCY AND SEVERE POST-VAGOTOMY DIARRHOEA.

(Eng.) McLoughlin, G. A.; Bradley, J.; Chapman, D. M.; Temple, J. G.; Hede, J. E.; McFarland, J. (Royal Southern Hosp., Liverpool, U.K.). *Lancet* 1(7952):168-170; 1976.

The occurrence of severe post-truncal vagotomy

rhea was investigated to determine classifications
atients who will be susceptible to this complica-
. Fourteen out of 2,058 patients developed
re diarrhea within 6 months after operation, and
following parameters were tested in the sera of
: IgA, IgG, IgM, IgE, C3, C4, antinuclear factor,
basement membrane antibodies, rheumatoid-factor
r, isohemagglutinin titer, and the presence of
bodies to egg albumen, yolk, milk proteins, and
en. Six of the 14 patients were asymptomatic
re operation, and were found to have no measurable
m IgA, IgM, or IgE. Jejunal biopsy was normal,
pt that in one patient it revealed partial vil-
atrophy. Each of the six subjects had markedly
ed urinary indican and IgA deficiency. It is
ested that antecedent IgA deficiency may account
the incidence of post-vagotomy diarrhea and that
perative screening can reduce the incidence of
complication.

5 PRIMARY GASTROINTESTINAL LYMPHOMAS:
CLINICAL, RADIOLOGICAL, AND THERAPEUTIC
SIDERATIONS BASED ON 42 CASES. (Fre.) Taleb, N.;
uri, K.; Nassr, W. (No affiliation given). *J.*
Liban. 28(2):233-258; 1975.

ty-two cases of primary gastrointestinal lymphomas
reviewed. Clinical findings indicate that the
ness occurs predominantly in men aged 20-50 yr,
is characterized by abdominal or epigastric
ns (92.5%), altered general health (82.5%), and
ominal mass (55%). Localizations are most fre-
ntly on the small intestine. Histologically,
iculosarcomas are most frequent, followed by
phosarcomas and Hodgkin's disease. Therapeu-
ally, complete resection is chosen when possible,
h chenotherapy as the second choice. Prognosis
gely depends upon the magnitude of the intestinal
sions. The extreme rarity of peripheral nodal in-
sion supports the hypothesis that primary gastro-
testinallymphomas constitute an independent and
tonomous disease from lymphomas of the lymph nodes.
wever, the peripheral invasion was observed as a
condary manifestation in two cases.

56 EFFECT OF STREPTOZOCIN ON GASTRIN RELEASE.
(Eng.) Stadil, F.; Stage, J. G. (Rigshospi-
let, 2100 Copenhagen, Denmark). *Scand. J. Gastro-*
terol. 11(Suppl. 37):67-70; 1976.

e action of streptozocin on normal gastrin release
s evaluated in six patients with carcinoid tumors
d in two patients with malignant insulinomas be-
use of the drug's toxic effect on gastrin producing
lls in some patients with gastrinomas. Streptozocin
s given in a dose of 2 or 4 g during 30-60 min at
tervals of 6-12 weeks; one patient was given the
ug i.v., while the others were given streptozocin
rough the hepatic or superior mesenteric artery.
e total dose ranged from 6 to 18 g, and the ob-
rvation period ranged from 3 to 18 months. Blood
r gastrin determination was drawn from an indwell-
g venous catheter during the first 19 hr after
treptozocin infusion in 22 instances (in 5 patients),
nd gastrin was determined radioimmunochemically.
treptozocin did not depress gastrin levels acutely
any of the patients. In all patients but one,
gastrin levels were doubled after 6 g of streptozocin was given during a 4-month period and they tripled after 10 g were given during a 9-month period. When the gastrin level at the time of the first treatment was compared with the level at the last treatment, the difference was significant ($p<0.01$). One patient with increasing gastrin levels developed a duodenal ulcer with massive bleeding after three infusions of 6 g. It is concluded that streptozocin does not damage normal gastrin-producing cells and that it stimulates gastrin release when given over prolonged periods. Peptic ulceration may be an important side effect during long-term treatment.

2667 MORPHOLOGICAL CHANGES OF THE SMALL INTESTINE FOLLOWING JEJUNO-ILEAL SHUNT IN OBESE SUBJECTS. (Eng.) Fenyo, G.; Backman, L.; Hallberg, D. (Karolinska sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(2):154-159; 1976.

Forty-seven patients underwent jejuno-ileal shunt operations (end-to-side or end-to-end) for massive obesity, and 17 of them had a second laparotomy for various reasons (cholelithiasis, 6; persisting obesity, 5; cicatrical hernia, 4; sterilization, 1; and jaundice, 1). At both operations, the length of the functioning jejunal and ileal segments was determined, and in biopsies, the intestinal villus height was determined. The second laparotomies were not performed until at least 6 months after establishment of jejuno-ileal bypass. The mean length of functioning jejenum was increased by 33% ($p<0.05$)and the mean elongation of functioning ileum by 73% ($p<0.001$). The mean villus height in functioning jejunum increased by 33% ($p<0.001$) and in functioning ileum by 70% ($p<0.001$). The mean villus height in the jejunal blind loop decreased by 30% ($p<0.001$). The demonstrated hypertrophic changes in the functioning part of the small intestine following jejuno-ileal bypass represent the morphological basis of functional intestinal adaptation. The effect of this adaptation is illustrated in the characteristic weight diagram of an obese patient after bypass operation: the loss of weight ceases, a period of stability ensues, and then the patient begins to regain weight to some extent. Thus, a balance seems to exist between the functional capacity of the intestinal mucosa and the body weight.

SMALL INTESTINE

Malabsorption

2693 MALIGNANCY IN RELATIVES OF PATIENTS WITH COELIAC DISEASE. (Eng.) Stokes, P. L.; Prior, P.; Sorahan, T. M.; McWalter, R. J.; Waterhouse, J. A. H.; Cooke, W. T. (General Hosp., Birmingham B15 2TJ, England). *Br. J. Prev. Soc. Med.* 30(1):17-21; 1976.

The incidence of malignancy in relatives of patients with celiac disease was compared with that of the general population to determine whether they also have an increased incidence of histocompatibility (HL-A) HL-A8 antigen. The study group consisted of 139 patients, and 1329 relatives including grandparents, parents, siblings of parents, and siblings of the patients. There was a significantly increased number of cancer deaths in the relatives ($p<0.001$), using the method of years at risk to calculate expected numbers of cancer deaths in the general population. In female relatives, the difference between observed and expected cancer deaths was highly significant ($p<0.01$). There was also an increase in cancer deaths among male relatives, but this was statistically insignificant. In the female relatives, the only site that showed a significant cancer excess was the breast. This analysis has not shown any general increase in deaths from cancer at all sites in relatives of patients with celiac disease. It has not been determined whether the excess of cancer at specific sites is due to a familial effect, independent of celiac disease, or whether it is the result of a small proportion of relatives with undiagnosed disease displaying an enhanced risk of certain cancers in a pattern similar to that in patients with established celiac disease.

2694 T CELL DEPLETION IN UNTREATED ADULT COELIAC DISEASE. (Eng.) O'Donoghue, D. P.; Lancaster-Smith, M.; Laviniere, P.; Kumar, P. J. (St. Bartholomew's Hosp., London EC1A 7BE, England). *Gut* 17(5):328-331; 1976.

Thymus dependent lymphocytes (T cells) were quantitated in 24 patients with treated adult celiac disease (ACD), 29 untreated patients, 39 healthy subjects (of comparable age, sex distribution, and nutritional status), and in 10 patients with malabsorption due to conditions other than celiac disease. The T cells were quantitated as peripheral blood cells that spontaneously formed rosettes with sheep RBC. For intra-epithelial lymphocyte counts, biopsies were obtained from the duodenojejunal flexure in 19 patients. The proportional and absolute numbers of T lymphocytes in the peripheral blood of patients with untreated ACD (42.4% T cells or 577 ± 51 T cells/ml) were decreased when compared with treated patients (62% or 1050 ± 95.5, $p<0.002$, $p<0.002$), controls (59% or 942 ± 58, $p<0.002$, $p<0.002$), and patients with malabsorption not due to celiac disease ($p<0.002$, $p<0.05$). Treated patients had the same proportional and absolute numbers of T cells as controls. Total peripheral blood lymphocytes did not differ significantly in the four groups. Nine patients who were studied both before and after treatment with a gluten-free diet showed a proportional rise in T cells ($p<0.001$). Jejunal intra-epithelial lymphocyte counts showed an inverse correlation with the proportional ($p<0.001$) and absolute ($p<0.01$) peripheral blood T cell counts. These results suggest that T cells may be involved in the pathogenesis of celiac disease and that their depletion in untreated patients may explain partially the associated cell-mediated immunodysfunction. Because normal numbers of circulating T cells were found in patients with malabsorption from conditions other than celiac disease, it is unlikely that the T cell depletion in untreated celiac disease is a manifestation of malabsorption per se.

2695 FOOD ANTIBODIES IN PATIENTS WITH DERMATITIS HERPETIFORMIS AND ADULT COELIAC DISEASE--RELATIONSHIP TO JEJUNAL MORPHOLOGY. (Eng.) Kumar, P. J.; Ferguson, A.; Lancaster-Smith, M.; Clark, M. L. (St. Bartholomew's Hosp., London, England). *Scand. J. Gastroenterol.* 11(1):5-9; 1976.

Serum antibodies to a variety of dietary proteins were investigated in 26 patients with adult celiac disease (ACD), in 38 patients with dermatitis herpetiformis (DH) and various small bowel abnormalities, and in 50 normal blood donors. Precipitating antibodies were detected using a micro-gel diffusion technique; crude antigens were prepared from gluten, wheat flour, oatmeal, rice flour, cow's milk, bovine calf serum, pig and horse serum, hen's egg white and yolk, and chicken serum. Passive hemagglutination was used to detect antibodies to five protein constituents of cow's milk. Antibodies to all food antigens were detected for all antigens except rice, egg white, and horse serum. The incidence of one or more positive tests was highest in 14 untreated ACD patients (73.4%) and in 13 patients with DH with subtotal villous atrophy (SVA, 57.4%). These values decreased with morphological improvement, being 56.4% in the 17 ACD patients with partial villous atrophy (PVA) who were treated with gluten-free diet, 33.4% in 16 patients with DH and PVA, and 0% in 9 patients with normal biopsies. The height of the serum antibody titer also fell with morphological improvement. There was no correlation between serum immunoglobulin (Ig) A, IgG, or IgM and the presence or absence of food antibodies; however, patients with the presence of both food and anti-reticulin antibodies had significantly higher mean IgG (1200 mg%) when compared to patients with neither of these antibodies (mean 860 mg%, $p<0.05$). Twenty-two of 71 patients had a positive anti-reticulin antibody: 7 of 14 with untreated ACD, 4 of 18 with treated ACD, 7 of 15 with DH and SVA, 3 of 17 with DH and PVA, and 1 of 7 with DH and a normal biopsy. Eleven patients were studied before and after 3 months on a gluten-free diet. Two patients had no antibodies before or after treatment. Of the remaining patients, all but one showed a decrease in antibody score; this patient showed deterioration in clinical symptoms and jejunal biopsy despite a gluten-free diet. The results indicate that there is an abnormally high incidence of dietary antibodies in patients with DH; this correlates with the degree of severity of small bowel damage.

2696 PROTEIN PATTERNS OF BRUSH-BORDER FRAGMENTS IN CONGENITAL LACTOSE MALABSORPTION AND IN SPECIFIC HYPOLACTASIA OF THE ADULT. (Eng.) Freiburghaus, A. U.; Schmitz, J.; Schindler, M.; Rotthauwe, H. W.; Kuitunen, P.; Launiala, K.; Hadorn, B. (Dept. Pediatrics, Univ. Berne, Berne, Switzerland). *N. Engl. J. Med.* 294(19):1030-1032; 1976.

Brush border membrane proteins of the small bowel mucosa were separated on polyacrylamide gels from intestinal biopsy specimens obtained from four children with congenital lactose malabsorption, from two adults with specific hypolactasia, and from one adult control. The protein pattern and the residual activity of lactase were compared. The protein band corresponding to brush border lactase was reduced in intensity, but was never completely absent in three patients with congenital malabsorption. No difference in gel patterns was detected when this pattern in congenital deficiency was compared to that obtained from the two patients with adult-type selective hypolactasia. In one patient with congenital lactose malabsorption, the protein band corresponding to lactase activity was not detectable. The results suggest that the mechanisms leading to low lactase activity in congenital and adult forms of lactose intolerance are similar. The hypothesis of a very early "switch off" of lactase biosynthesis seems to be confirmed.

2697 ENTEROTOXIGENIC INTESTINAL BACTERIA IN TROPICAL SPRUE: IV. EFFECT OF LINOLEIC ACID ON GROWTH INTERRELATIONSHIPS OF Lactobacillus acidophilus AND Klebsiella pneumoniae. (Eng.) Mickelson, M. J.; Klipstein, F. A. (Bigelow Lab. Ocean Science, West Boothbay Harbor, ME 04575). *Infect. Immunol.* 12(5):1121-1126; 1975

The effect of linoleic acid on the growth interrelationships of *Lactobacillus acidophilus* and *Klebsiella pneumoniae* was investigated in patients with tropical sprue, using a glucose limited continuous culture system. The culture system consisted of bacteria from a normal fasted subject, and from a patient with overt, untreated tropical sprue. *K. pneumonia* did not grow, even after a period of 96 hr, when the pH of the medium was acidified to 5.6 prior to inoculation by the addition of 100 μmol of either hydrochloric or lactic acid. Maximum growth occurred within 20 hr when the initial pH was 6.8. One gram per liter of glucose in the medium was required for *L. acidophilus* to produce enough lactic acid to reduce the pH. When the population density of *L. acidophilus* was reduced by the presence of a sufficient concentration of linoleic acid (1 mg/ml), the invading *K. pneumonia* successfully colonized the system and, once established, suppressed the growth of *L. acidophilus* The results indicate that gram positive enteric bacteria suppress coliform growth and that this effect is reversible by the addition of linoleic acid.

2698 UNUSUAL ANOMALY OF THE SMALL INTESTINE WITH MALABSORPTION. (Eng.) Palmer, P. E.; Ruiz, U.; Stadecker, M. J. (New England Medical Center Hosp., 171 Harrison Ave., Boston, MA 02111). *Am. J. Dis. Child.* 130(3):330-332; 1976.

LARGE INTESTINE

2703 THE PRECURSOR TISSUE OF ORDINARY LARGE BOWEL CANCER. (Eng.) Lane, N. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *Cancer Res.* 36(7):2669-2672; 1976.

Information regarding the morphological origin of large bowel neoplasia is reviewed. Hyperplastic polyps are 10 times as common as adenomas and must be distinguished from them since they are unrelated as a precursor tissue to either adenomas of carcinomas. Only adenomas are relevant to the development of the common moderately and well-differentiated large bowel cancer. Depending upon three related factors (increasing size, a sessile rather than pedunculated mode of growth, and a villous rather than tubular microscopic architecture), minute (1- to 2-mm) carcinomas or microcancer may be found with increasing frequency in adenomas. Minute or microcancer has not been observed in normal mucosa, i.e., unassociated with adenomatous tissue. In familial polyposis, adenomas (but not carcinomas) as small as one or two crypts have been found in grossly normal areas of mucosa. Direct one-step transformation from normal crypt cells to cancer, without formation of adenomatous epithelium, does not seem to be the usual pathway. It is suggested that human polyposis is the best model for the study of large bowel neoplasia.

2704 LYMPHOID HYPERPLASIA OF THE COLON: (2 CASE PRESENTATIONS). (Eng.) Ferran, J. L.; Betoulieres, P.; Bonnet, H.; Pous, G.; Jean, R. (Hopital Saint-Charles, F 34000 Montpellier, France). *Ann. Radiol.* 18(4):489-498; 1975.

Two cases of lymphoid hyperplasia of the colon (LHC) in young male infants are presented. A premature infant of 35 weeks gestation presented at 35 days of life with a febrile intestinal obstruction and minimal enterocolitis for which an emergency ileostomy was performed. At 10 months of age, a barium enema revealed the characteristic appearance of lymphoid hyperplasia, which was no longer found 7 months later. In the second case, intestinal obstruction related to Hirschsprung's disease was noted on the second day of life. Following 2 months of medical management, a clinical diagnosis of secondary enterocolitis was confirmed by laparotomy. A right-sided biopsy of the colon demonstrated multiple normal ganglion cells. The typical aspect of lymphoid hyperplasia with epithelial destruction and mucosal glands adjacent to these foci was noted and a right ileostomy was performed. At 17 months of age, the ileostomy was closed and was replaced by a left colostomy, awaiting definitive surgery. Colon biopsy confirmed the presence of chronic inflammatory infiltrations. It is suggested that the moderate initial lesions of enterocolitis and the lymphoid hyperplasia are related. In neither case did symptoms indicate intestinal tract involvement. LHC was probably benign. The diagnosis was made by double contrast barium enema that demonstrated disseminated, often umbilicated nodules of uniform size. It is suggested that LHC is not a disease, in itself, but is a simple exaggeration of a physiologic defense mechanism.

2705 LYMPHOID TISSUE AND LYMPHOID-GLANDULAR COMPLEXES OF THE COLON: RELATION TO DIVERTICULOSIS. (Eng.) Kealy, W. F. (King's Coll. Hosp., London, England). *J. Clin. Pathol.* 29(3): 245-249; 1976.

The relation of lymphoid-glandular complexes and the lymphoid tissue of the colon to the development of diverticulosis was studied. In 50 colons with diverticula, the number of lymphoid nodules per square centimeter, expressed as an average for the colon as a whole (excluding the cecum and the areas containing diverticulae), ranged from 2.4 to 9.5; in 50 colons without disease, it ranged from 1.5 to 7.3; and in 3 specimens from Nigerian patients, it ranged from 3.1 to 3.9. In 351 partial and total colectomy specimens examined microscopically, lymphoid-glandular complexes were observed in 51 cases. These complexes were always associated with a lymphoid nodule and protruded through a gap in the muscularis mucosa. It is concluded that the lymphoid nodules in apposition to the muscularis mucosae may constitute weak points in the bowel wall, that the increase in their number in diverticular disease may represent a prediverticular state, and that these and the lymphoid-glandular complexes may play a part in the pathogenesis of diverticula.

2706 COLONIC PSEUDO-OBSTRUCTION: A NEW COMPLICATION OF JEJUNOILEAL BYPASS. (Eng.) Barry, R. E.; Benfield, J. R.; Nicell, P.; Bray, G. A. (Bristol Royal Infirmary, Bristol, England). *Gut* 16(11):903-908; 1975.

The cases of five patients in whom jejunoileal bypass (3 end-to-side and 2 end-to-end) was complicated 1.5-3 yr later by symptoms of colonic pseudo-obstruction are reported. The patients were all women, aged 25-44 yr, and the operation was performed for morbid obesity in all cases. In each case, the colon was markedly elongated, dilated, and atonic, but there was no demonstrable organic obstruction. Full thickness rectal biopsy in one case showed normal intrinsic nervous plexuses and ganglia.

Serum electrolytes were normal. Functional and defunctionalized small bowel were not involved. Symptoms varied from complete colonic paralysis to incapacitating crampy abdominal pain and distention. In the three patients with end-to-side bypass, dilatation affected the entire colon; in the two patients with end-to-end bypass, the dilatation was localized to colon distal to the anastomosis with the defunctionalized small bowel. In one case, resection of the affected portion of the colon resulted in recurrence distal to the new site of drainage of defunctioned bowel. In two cases, treatment with anti-anaerobe antibiotics (metronidazole in both cases, kanamycin in one case, and clindamycin in the other) produced dramatic but temporary relief of symptoms. These preliminary observations suggest that bacterial overgrowth in the defunctionalized loops of small bowel may play an important role in the development of colonic pseudo-obstruction.

2707 PHYSIOPATHOLOGY OF MEGARECTUM: THE ASSOCIATION OF MEGARECTUM WITH ENCOPRESIS. (Eng.) Meunier, P.; Mollard, P.; Marechal, J.-M. (Hopital Debrousse, 69322 Lyon Cedex 1, France). *Gut* 17(3): 224-227; 1976.

Studies were performed on 15 control subjects and on 61 children with a radiological megarectum (70% were encopretics) to determine a correlation between the frequency of encopresis and a decrease in conscious rectal sensitivity. Pressure measurements were performed using a tandem system of three side-opening PVC catheters connected to an electromanometer and thermal-tip recorder. In control subjects, the reflex threshold of internal sphincter relaxation (mean distension 15.33 ml) and the rectal sensitivity threshold (mean 14.66 ml) were obtained with a comparable volume of rectal distension. In children with megarectum, the reflex threshold (mean 15.33 ml) was not modified, but sensitivity was often considerably reduced, and the incidence of encopresis increased proportionally with the decrease in sensitivity. On the basis of sensitivity measurements, the megarectum patients were segregated into three groups: 32% of those with a mean sensitivity threshold of 29.0 were ençopretics, probably due to psychogenic factors; 82% of children with a mean threshold of 83.85 were encopretics; and those with a mean of 209.33 were all encopretics.

LARGE INTESTINE
Ulcerative Colitis

2758 INFLAMMATORY BOWEL DISEASE IN ALL THREE MEMBERS OF ONE FAMILY. (Eng.) Rosenberg, J. L.; Kraft, S. C.; Kirsner, J. B. (Dept. Medicine, Univ. Chicago, 950 East 59th St., Chicago, IL 60637). *Gastroenterology* 70(5):759-760; 1976.

The occurrence of inflammatory bowel disease in all three members of one family are described. Inflammatory bowel disease occurred in a mother, followed 7 and 9 yr later by the disease in her 7-yr-old son and her husband, resp. A diagnosis of ulcerative colitis, ulcerative proctitis, and Crohn's disease was made in the mother, son, and husband, resp. Blood counts, serum protein electrophoresis, febrile agglutinins, and leukocyte karotypes were normal in all three family members. Cellular and humoral immunity also failed to explain this phenomenon, and histocompatibility antigen W27 was not detected. The appearance of inflammatory bowel disease in an entire family emphasizes the potential role of genetic and environmental influences in the pathogenesis of some cases of ulcerative colitis and Crohn's disease.

2759 UNEXPLAINED BRONCHOPULMONARY DISEASE WITH INFLAMMATORY BOWEL DISEASE. (Eng.) Kraft, S. C.; Earle, R. H.; Roesler, M.; Esterly, J. R. (Univ. Chicago, Hosp. Box 400, 950 E. 59th St., Chicago, IL 60637). *Arch. Intern. Med.* 136(4):454-459; 1976.

The case reports and the clinical and laboratory data of six patients who developed severe, unexplained, chronic bronchopulmonary disease 3-13 yr after the onset of nonspecific inflammatory disease of the colon are presented. All had chronic bronchitis; bronchiectasis was diagnosed in four, and an obstructive type of pulmonary dysfunction was noted in five. Four of the six, including the two with only chronic bronchitis, had no history of smoking. There was an initial correlation between the pulmonary symptoms and the intestinal disease, except in two patients who developed overt pulmonary disease following total proctocolectomy. The frequent occurrence of extra-intestinal lesions suggests that ulcerative colitis and regional enteritis are systemic disorders; chronic unexplained bronchopulmonary disease may be another infrequent complication in such patients.

2760 SERUM LYSOZYME IN INFLAMMATORY BOWEL DISEASE. (Eng.) Nugent, F. W.; Mallari, R.; George, H.; Ridley, N. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Gastroenterology* 70(6):1014-1016; 1976.

Serum lysozyme (muramidase) concentrations were measured in 3 groups of patients--49 controls, 21 patients with ulcerative colitis and proctitis, and 63 patients with Crohn's disease--to determine its effectiveness in the differential diagnosis of Crohn's disease. The mean concentration for each group was 7 ± 2 for controls, 7 ± 2 for patients with ulcerative colitis and proctitis, and 10 ± 4 for patients with Crohn's disease ($p<0.0005$). All patients with ulcerative colitis and proctitis and only 1 patient in the control group had a serum lysozyme level greater than normal (12 μg/ml). Of the Crohn's group, 43 patients (68%) had serum lysozyme levels of 11 μg/ml or less, and 20 patients (32%) had serum lysozyme levels greater than 11 μg/ml. The relation of the serum lysozyme level to total WBC count, polymorphonuclear leukocyte count, and monocyte count was studied; the only significant relation was with total WBC count ($n=60$, $r=0.243$, and $-0.05<p<0.10$). There was no relation between the level of serum lysozyme and the activity of the Crohn's disease, severe, moderate, mild, or remission ($0.25<p<0.50$). There was an inverse relation between the serum lysozyme level and the presence of extracolonic manifestations ($0.02<p<0.05$, $t=2.048$). Although a significant difference was observed between values in patients with Crohn's disease and values observed in those with ulcerative colitis or control patients, an important overlap was found between these groups. Further studies are necessary to explain the disparate results between this study and previous reports.

2761 CLINICAL AND IMMUNOLOGICAL ASPECTS OF PATHOGENESIS AND TREATMENT OF ULCERATIVE COLITIS IN CHILDREN. (Eng.) Schafer, K. H.; Blaker, F. (Universitats-Kinderklinik Hamburg, Hamburg, W. Germany). *Paediatrician* 5(1/2):57-66; 1976.

The definition, the clinical and immunological aspects of pathogenesis, and the clinical and immunological aspects of therapy in childhood ulcerative colitis are reviewed. Ulcerative colitis is a rare nonspecific inflammatory bowel disease with increasing frequency in children. It differs from the closely related granulomatous colitis (Morbus Crohn) by some clinical, histological, immunological, and especially biochemical findings. The etiology and pathogenesis of the disease are unknown. Some observations indicate that the disposition to unspecific inflammatory bowel disease is based upon genetic factors. The concept of an immunopathogenesis of ulcerative colitis is based upon the frequency of this disease with autoimmune diseases and autoallergic reactions, on immunologic findings of activated immune reactions against colonic protein and other autoantigens, on circulating immune complexes, and on an alteration of the complement system. Whenever steroids and azulfidine do not help in patients with frequent relapses, it is possible to induce remissions with azathioprine. Relapses are less frequent during therapy with azathioprine as compared to therapy with only steroids and azulfidine. The long-term effects of immunosuppressive therapy on this disease and on immunologic function in children with ulcerative colitis are unknown.

2762 SERUM OROSOMUCOID IN ULCERATIVE COLITIS: ITS RELATION TO CLINICAL ACTIVITY, PROTEIN LOSS, AND TURNOVER OF ALBUMIN AND IgG. (Eng.) Jensen, K. B.; Jarnum, S.; Koudahl, G.; Kristensen, M. (Rigshospitalet, DK-2100, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(2):177-183; 1976.

Serum orosomucoid, hemoglobin, and erythrocyte sedimentation rate (ESR) values were compared with clinical disease activity, intestinal protein loss, and albumin and IgG turnover in 22 patients with ulcerative colitis. The disease activity was graded into three categories (inactive, mild, or severe) according to the number of bowel movements per day, and the degree of fever and tachycardia. Disease activity showed no correlation with the hemoglobin measurements ($p>0.10$) or ESR ($p>0.10$) but more severe disease was associated with higher serum orosomucoid concentration ($p<0.01$). More severe colitis was associated with increased gastrointestinal protein loss, decreased serum albumin, increased fractional catabolic rate of albumin and IgG, and increased IgG synthesis rate. Serum orosomucoid was negatively correlated to serum albumin and positively correlated to fractional catabolic albumin and IgG rates, gastrointestinal protein loss, and ESR. It is concluded that serum orosomucoid is a reliable indicator of clinical activity in ulcerative colitis and is superior to hemoglobin and ESR determinations.

2763 POLYPOSIS IN ULCERATIVE COLITIS. (Eng.) Teague, R. H.; Read, A. E. (Bristol Royal Infirmary, Bristol, England). *Gut* 16(10):792-795; 1975.

The occurrence of inflammatory polyposis following severe colitis was assessed in 150 patients, by total colonoscopy and multiple biopsies taken at intervals of 10 cm. Inflammatory polyposis was found in 25 patients, and 6 of them had a large (>1.5 cm) solitary polyp, which radiologically resembled carcinoma, in 4 cases. Adenomatous polyps were observed in four patients. Three carcinomas were found at endoscopy, of which two were entirely unsuspected. In all cases, endoscopic polypectomy or surgical intervention was performed to establish the exact histologic diagnosis. It is suggested that the use of endoscopic examination of the bowel in ulcerative colitis may eliminate, or at least delay, the need for colectomy, until the clinician is sure that it is required.

2764 INHIBITION OF LEUCOCYTE MIGRATION BY ANTIGENS FROM HUMAN COLON AND E. coli O 14 IN PATIENTS WITH ULCERATIVE COLITIS. (Eng.) Fixa, B.; Komarkova, O.; Skaunic, V.; Nerad, M.; Kojecky, Z. (Second Dept. Medicine, 500 36 Hradec Kralove, Czechoslovakia). *Scand. J. Gastroenterol.* 10(5): 491-493; 1975.

The leukocyte migration inhibition test was performed in 55 patients with ulcerative colitis and in 25 controls. The extract from human fetal colon and the lipopolysaccharide antigen from *Escherichia coli* O 14 were used as antigens. The leukocyte migration in patients with ulcerative colitis was significantly inhibited in the presence of these antigens. In the 21 patients with an active form of ulcerative colitis the leukocyte migration was significantly inhibited as compared to the leukocyte migration in patients with a nonactive form of the disease. The results support the suggestion that in ulcerative colitis, autoimmunization to colon may be induced through stimulation with cross-reacting bacterial antigens.

2765 DEFICIENCY OF ALPHA-1-ANTITRYPSIN, FATTY LIVER AND ULCERATIVE COLITIS. A HITHERTO UNKNOWN SYMPTOM-COMPLEX WITH ACCOUNT OF FAMILIAL PREDISPOSITION. (Dan.) Pedersen, J. K. (Tage Hansens Gade 23 st. tv., DK-8000 Arhus C, Denmark). *Ugeskr. Laeger* 136(49):2741-2744; 1974.

The case of a 13-yr-old girl with ulcerative colitis, fatty liver, and α-1-antitrypsin deficiency is presented. A pedigree study indicated that the α-1-antitrypsin deficiency was a recessive hereditary trait, because both parents had the Pi-type MZ genotype, while the patient had Pi-type ZZ. There was a high incidence of pulmonary disease in the mother's family, together with α-1-antitrypsin values occurring at low normal levels. Low values for α-1-antitrypsin levels were also found in the father's siblings, although there was no association with pulmonary disease. It is concluded that the enzyme deficiency facilitated the development of ulcerative colitis in this patient and that the fatty liver was probably secondary to the ulcerative colitis, as no evidence of primary liver disease was found.

PANCREAS

2775 PANCREATIC ASCITES: RECOGNITION AND MANAGEMENT. (Eng.) Sankaran, S.; Walt, A. J. (Wayne State Univ. Sch. Medicine, 540 E. Canfield, Detroit, MI 48201). *Arch. Surg.* 111(4):430-434; 1976.

Thirty-one episodes of pancreatic ascites in 26 alcoholic patients treated between 1958 and 1975 were analyzed. Twenty patients (65%) experienced abdominal pain and 10 (32%) had concomitant pleural effusions roentgenographically. Although a leaking pancreatic pseudocyst was the cause of ascites in at least 21 episodes (70%), an abdominal mass could only be palpated in 2 of 26 patients. Roentgenographic series of the upper part of the gastrointestinal tract failed to demonstrate pancreatic pseudocyst in 7 of 21 episodes (33%). Endoscopic retrograde pancreatography in conjunction with intraoperative pancreatography made a vital contribution to surgical therapy. Medical treatment or external drainage during 18 episodes resulted in death in 4 (22%) and recurrences of ascites or pancreatic pseudocyst in 9 (64%). Since routine pancreatography followed by pancreatic resection or internal drainage has been instituted, mortality and recurrence have been reduced to zero. The authors conclude that definitive procedures that attack the site of the leakage directly are the preferred technique for the treatment of pancreatic ascites, unless the degree of inanition, the acuteness of associated pancreatitis, or the nature of the pseudocyst makes external drainage the only feasible approach.

2776 SUBCUTANEOUS FAT NECROSIS ASSOCIATED WITH PANCREATIC DISEASE. (Eng.) Hughes, P. S. H.; Apisarnthanarax, P.; Mullins, J. F. (Univ. Texas Medical Branch, Galveston, TX 77550). *Arch. Dermatol.* 111(4):506-510; 1976.

The case of a 58-yr-old man who presented with subcutaneous fat necrosis associated with asymptomatic pancreatic disease is presented. The patient had a long history of alcoholism. About 25 erythematous nontender subcutaneous nodules (1-5 cm diameter) were present over the lower part of the back, buttocks, thighs, and lower areas of the legs. The histological findings consisted of focal fat necrosis and "ghost-like" cells with thick, shadowy walls and no nuclei. Distant foci of fat necrosis are probably due to the local action of hematogeneous-borne trypsin and lipase. Treatment consisted of anticholinergic medication, low-fat diet, leg elevation, and support stockings, which alleviated the symtpoms. Because underlying pancreatic disease may be asymptomatic, histopathological study of all cases of panniculitis, particularly those occurring in older men, should be undertaken.

2777 EFFECTS OF SHOCK ON THE PANCREATIC ACINAR CELL: CELLULAR AND SUBCELLULAR EFFECTS IN HUMANS. (Eng.) Jones, R. T.; Garcia, J. H.; Mergner, W. J.; Pendergrass, R. E.; Valigorsky, J. M.; Trump, B. F. (Univ. Maryland Sch. Medicine, Baltimore, MD 21201). *Arch. Pathol.* 99(12):634-644; 1975.

The effects of varying degrees of shock on the pancreatic acinar cell were studied in 22 patients within minutes of somatic death. The tissues were fixed, sectioned, stained, and examined by light and electron microscopy. By light microscopy, it was difficult to ascertain any differences among the shock groups (mild, moderate, and severe). Electron microscopy disclosed subcellular alterations that could be correlated well with the type, severity, and duration of shock. Mild cases of shock or shock of short duration showed mild cell damage, while extreme cases of hemorrhagic or septic shock showed cell death and necrosis. No morphological evidence for lysosomal initiation of damage was seen, but it is clear that the pancreas can undergo severe cell injury during shock, resulting in the release of further damaging enzymes, most probably from zymogen granules rather than from lysosomes. The results indicate that changes characteristic of the cellular response to acute lethal or sublethal injury occur in human pancreatic acinar cells during shock.

PANCREAS

Pancreatitis

2794 A PROSPECTIVE STUDY TO DETERMINE THE EFFICACY OF ANTIBIOTICS IN ACUTE PANCREATITIS. (Eng.) Finch, W. T.; Sawyers, J. L.; Schenker, S. (Dept. Surgery, Vanderbilt Univ., Nashville, TN). *Ann. Surg.* 183(6):667-671; 1976.

The efficacy of prophylactic antibiotic treatment (Ampicillin) was evaluated in 58 patients with acute alcohol-induced and idiopathic pancreatitis and in 27 controls in a double-blind, randomized, prospective study. Thirty-one patients received antibiotics: 19 received 500 mg Ampicillin every 6 hr, 11 received 1 gm every 6 hr, and 1 patient received 1 g Keflin every 6 hr for 7 days. The groups were compared to determine: length of hospitalization, number of days required to return to a normal serum amylase value, number of days required for the patient to become afebrile, complication rate, and recurrence rate. No statistically significant difference was found in any of the parameters except the recurrence rate, which was higher in the antibiotic group. These data indicate that prophylactic use of Ampicillin is not indicated in patients with routine acute alcohol-induced or idiopathic pancreatitis. The role of prophylactic antibiotics in patients with pancreatitis related to biliary calculi and those with more severe varieties of acute hemorrhagic or necrotizing pancreatitis must be more clearly defined.

2795 CHANGES OF THE NITROGEN METABOLISM IN PATIENTS WITH ACUTE PANCREATITIS AND CHOLECYSTOPANCREATITIS. (Rus.) Kovalyov, M. M.; Teplyi, K. V.; Shuliarenko, V. A. (Suvorov St. 19, Apt 46, Kiev-10, USSR). *Klin. Khir.* (5):13-18; 1975.

Nitrogen metabolism was investigated in 52 patients with acute pancreatitis and in 65 patients with cholecystopancreatitis. The patients with acute pancreatitis showed hypoproteinemia, hypoalbuminemia, reduction of blood urea level and total nitrogen in 24-hr urine, increased residual blood nitrogen, hyperglobulinemia (due to α-1, α-2, and gamma-globulins), and increased urinary excretion of amine nitrogen. These changes were most pronounced in destructive forms of pancreatitis. The use of protein agents and anabolic steroids in the complex treatment of patients with pancreatitis promoted normalization of the nitrogen metabolism.

2796 MAJOR ARTERIAL HEMORRHAGE: A COMPLICATION OF PANCREATIC PSEUDOCYSTS AND CHRONIC PANCREATITIS. (Eng.) Stanley, J. C.; Frey, C. F.; Miller, T. A.; Lindenauer, S. M.; Child, C. G., III. (Univ. Hosp., 1405 E. Ann St., Ann Arbor, MI 48104). *Arch. Surg.* 111(4):435-440; 1976.

Clinical experience with 12 patients, aged 18-68 yr, with major arterial hemorrhage as a direct complication of pancreatic pseudocysts and chronic pancreatitis is presented. Chronic alcoholism (11 patients) and blunt abdominal trauma (1 patient) were the basis for pancreatic disease. Spontaneous hemorrhage occurred in eight patients. Bleeding into the gastrointestinal tract occurred in eight patients; bleeding into the peritoneal cavity occurred in four patients; and it was intracystic in one patient. Splenic, pancreaticoduodenal, gastroduodenal, and gastroepiploic arteries were the sources of hemorrhage. Operative procedures included local control of bleeding in six patients, distal pancreatectomy in three patients, and pancreaticoduodenectomy in one patient. Four patients died of hemorrhagic complications of pancreatic disease, including one not subjected to operation. It is suggested that extirpation of diseased pancreatic tissue may lessen the morbidity and mortality attributed to this complication of pancreatitis.

2797 PERSISTENT OBSTRUCTIVE JAUNDICE, CHOLANGITIS, AND BILIARY CIRRHOSIS DUE TO COMMON BILE DUCT STENOSIS IN CHRONIC PANCREATITIS. (Eng.) Warshaw, A. L.; Schapiro, R. H.; Ferrucci, J. T., Jr.; Galdabini, J. J. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 70(4): 62-67; 1976.

The diagnostic approach to and treatment of six patients with common bile duct obstruction complicating chronic pancreatitis are presented. The most frequent symptoms included: painless obstructive jaundice, recurrent cholangitis, secondary biliary cirrhosis, and chronic abdominal pain. These symptoms were often attributed to the pancreatitis, cirrhosis of the liver, or alcoholic hepatitis. Diagnosis of the biliary obstruction was effectively completed using either endoscopic retrograde cholangiopancreatography or operative cholangiography. Biliary bypass, by anastomosis of the common bile duct to the small intestine, relieved symptoms and improved liver function during the first postoperative year. It is suggested that stenosis of the common bile duct be considered in any diagnosis of chronic pancreatitis or whenever surgical treatment of pancreatitis is contemplated. Recognition of acute cholangitis is important since it requires immediate antibiotic therapy and surgical decompression after sepsis has been controlled.

LIVER AND BILIARY TRACT

2805 SERUM BILE ACID CONCENTRATION AFTER A TEST MEAL. (Eng.) Fausa, O. (Natl. Hosp. Norway, Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(3):229-232; 1976.

Total serum bile acid concentrations were studied in six healthy subjects and in seven patients with hepatobiliary disease by an enzymatic-fluorimetric method employing a highly purified 3 α-hydroxysteroid dehydrogenase. In an additional 28 control subjects, mean total serum bile acid concentration was determined to be 2.5 μmol/l (standard deviation, 1.4). In the six healthy subjects, a significant postprandial increase in total serum bile acids occurred, with maximal values at 90 and 120 min after ingestion of a liquid test meal, and it returned to base-line levels within 3.5 hr. The maximal postprandial increase for each subject was(1.5-3 times the fasting value. In the seven patients with various hepatobiliary diseases, the maximal postprandial elevation of serum bile acids was higher than in the normals, and the duration of serum bile acid elevation was significantly prolonged, not returning to fasting level within 4 hr. In the patients with normal fasting concentration of bile acids, the postprandial elevation was also significantly greater than in the controls. A 2-hr postprandial sample seems suitable for the study of the bile acid test meal response for clinical use. It is concluded that the enzymatic fluorimetric procedure permits accurate and precise measurement and is simple enough to be used routinely for liver function analysis.

2806 CLASSIFICATION OF LIVER DISEASES BY CLINICAL CHEMICAL LABORATORY RESULTS AND CLUSTER ANALYSIS. (Eng.) Solberg, H. E.; Skrede, S.; Elgjo, K.; Blomhoff, J. P.; Gjone, E. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Clin. Lab. Invest.* 36(1):81-85; 1976.

Seventy-eight patients with chronic liver disease were classified by cluster analysis, using only clinical chemical laboratory results. These results were compared with earlier findings, by discriminant analysis of laboratory results, which indicated that the classifications based on morphological (based mainly on biopsy findings) and functional criteria were consistent. Clinical diagnoses included chronic active hepatitis, chronic persistent hepatitis, alcoholic cirrhosis, cryptogenic cirrhosis, primary bilia cirrhosis (chronic liver diseases), acute hepatitis, and steatosis hepatitis. Although an exact correspon ence between the two systems of classification was no found, there was a strong tendency towards consistenc The greatest discrepancy between the two classificati systems was observed when patients who were primarily classified as having one of the five chronic liver di eases were clustered. Some of the causes for the discrepancies are discussed.

2807 REVERSED LIVER-SPLEEN RATIO AND THE NORMAL LIVER SPLEEN SCINTIGRAM. (Eng.) Harvey, W. C.; Kopp, D. T.; Podoloff, D. A.; Russell, D. C.; Brunstetter, F. L. (Presbyterian Hosp., 8200 Walnut Hill Lane, Dallas, TX 75231). *J. Reticuloendothel. Soc.* 19(1):19-27; 1976.

A liver-spleen phantom study was performed to determine the approximate ratio of spleen to liver activity necessary to make the spleen appear scintigraphically brighter than the liver. Liver scans were performed 20-30 min after injection of 2 mCi TcSC. Comparative scintigraphic brightness was evaluated from the anterior view. Plasma disappearance of the colloid was assessed by drawing blood 1-10 min after i.v. injections. The rate of uptake in the liver and spleen was determined in three patients by video-tape storer. Of 524 concurrent liver scans (408 showed malignancy), 24 showed the phenomenon of increased splenic uptake. Eighteen of these (75%) had a malignancy. Differences in $T_{1/2}$ plasma disappearance time and liver spleen uptake rates were not significant in patients with scintigraphically normal liver spleen scans as compared with patients with the "hot spleen" phenomenon. For equal thickness of tissue equivalent material (0.5 cm) between the liver and collimator, and the spleen and collimator, the spleen did not appear scintigraphically brighter until the total activity in the liver was 2.7 times that in the spleen. This corresponds to a concentration ratio for spleen to liver of 3.7:1. When the spleen had 2 cm more absorber than the liver between the collimator and phantom, the spleen appeared scintigraphically brighter, giving a liver to spleen activity ratio of 1:1. This corresponds to a spleen to liver concentration ratio of 5.3:1. Finally, for 4 cm more absorber between collimator and spleen than between collimator and liver, the spleen appeared scintigraphically brighter for a spleen to liver activity ratio of 1.4:1. This corresponds to a spleen to liver concentration ratio of 7.1:1. The data suggest that blood flow does not account for greater splenic than liver accumulation of colloid.

2808 LIVER IMAGING IN THE DIAGNOSIS OF HEPATIC VENOUS THROMBOSIS IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA. (Eng.) Staab, E. V.; Hartman, R. C.; Parrott, J. A. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514). *Radiology* 117(2): 341-348; 1975.

The use of liver imaging with technetium (^{99m}Tc) is reported in 11 cases of patients with paroxysmal nocturnal hemoglobinuria (PNH), 4 of whom also developed hepatic venous thrombosis (HVT). Liver imaging results correlated with pertinent clinical, radiologic, and pathologic findings in all cases. Six patients were alive, and four of them were treated with androgens and one with adrenocorticosteroids. Autopsy evidence in four cases showed multiple thromboses. Four cases of 8-16 yr duration had consistently normal liver images. Three cases showed consistently abnormal liver images for 5-6 yr. Liver imaging showed evidence of progressive HVP in four cases. A 59-yr-old man with a 5-yr history of PNH, during which his serum bilirubin continually rose, had image evidence of HVT and he subsequently died. A 54-yr-old man with a 10-yr history of PNH originally had a normal scan, but shortly before death, evidence of HVT appeared in the liver scan. Rapidly developing changes in the liver scan occurred in a 20-yr-old man who presented with pancytopenia 2 yr after spray painting his car in an enclosed space. At autopsy, only a single left hepatic vein was patent. A 25-yr-old woman died 12 yr after the diagnosis of PNH, as the result of HVT and pulmonary embolus. Her liver scan revealed evidence of HVT during an acute terminal episode. It is concluded that serial liver images are helpful in the diagnosis of HVT in PNH when considered in the clinical setting. Abnormal patterns include enlargement of the liver, especially of the right lobe, extrahepatic localization of radionuclide, and areas of decreased uptake in the distribution of the involved veins.

2809 LIVER ENLARGEMENT DEMONSTRATED BY SCINTIGRAPHY IN RHEUMATOID ARTHRITIS. (Eng.) Tiger, L. H.; Gordon, M. H.; Ehrlich, G. E.; Shapiro, B. (Albert Einstein Medical Center, Philadelphia, PA 19141). *J. Rheumatol.* 3(1):15-20; 1976.

Liver and spleen sizes were assessed in 32 patients with rheumatoid arthritis (RA), using scintigraphic techniques with technetium-99m sulfur colloid. Seven patients were shown to have enlarged livers, and three enlarged spleens. No correlation was found between splenomegaly and hepatomegaly and none was found between hepatomegaly and Sjogren's and Felty's syndromes (syndromes frequently present with RA). Hepatomegaly correlated best with increased titers of rheumatoid factor, suggesting increased reticuloendothelial activity in these patients. A less pronounced correlation existed between hepatomegaly and dysproteinemia. It is concluded that hepatomegaly may be a manifestation of RA and is, therefore, not necessarily an indication of adverse treatment results or of the development of lymphoproliferative disorders. In addition, scintigraphy provides a more exact assessment of liver size than does palpation or percussion, and it should be used in the diagnosis of RA.

2810 ENZYME ACTIVITIES IN HEPATIC VENOUS BLOOD UNDER STRENUOUS PHYSICAL EXERCISE. (Eng.) Fojt, E.; Ekelund, L.-G.; Hultman, E. (Silesian Sch. Medicine, PL-40-752 Katowice, Poland). *Pfluegers Arch.* 361(3):287-296; 1976.

The influence of physical exercise on liver function was investigated in 23 healthy volunteer men who were subjected to controlled major physical effort. Blood samples obtained by catheterization of the hepatic vein during exercise were analyzed for activities of LD (thermostabile and thermolabile isoenzymes), alanine aminotransferase (AlAT), sorbitol dehydrogenase (SDH), isocitrate dehydrogenase (ICD), alkaline phosphatase (AP), and activated creatine phosphokinase (CPK). These activities were compared with corresponding values in simultaneously taken arterial blood samples. In the LD test, there were no significant differences (NSD) between the two blood samples in three patients, while in three other patients, the hepatic venous activity was greater than systemic arterial activity. Two of these were at the significant level ($p<0.01$, $p<0.05$, and $p<0.05$). For the SDH there were three cases with NSD, while in the other three, hepatic venous activity was greater (two at the significant level, $p<0.01$ and $p<0.1$). In the ICD test, there was one case of NSD, and four cases of higher hepatic venous activity, three at the significant level ($p<0.05$, $p<0.1$, and $p<0.05$). There were no significant differences in any cases during the AP test. During the CPK test, there were three cases of NSD and one case in which the systemic arterial activity was greater than the hepatic venous activity ($p<0.01$). It is concluded that during intensive physical exercise some specific enzymes are released from the splanchnic area into the blood. In addition, exhausting exercise may induce an increased hepatocyte membrane permeability in man.

2811 EXCRETION OF LIVER ANTIGENS IN THE URINE OF PATIENTS WITH HEPATIC DISEASES. (Eng.)

Boss, J. H.; Rosenmann, E.; Dishon, T.; Slavin, S.; Eliakim, M. (Hebrew Univ.-Hadassah Medical Sch., B.O.B. 1172, Jerusalem, Israel). *Res. Exp. Med.* 167(1):51-59; 1976.

Hepatic damage in 42 patients with various liver disease was assessed by urinalysis for hepatic antigens. The tests that were performed in all patients and in seven healthy controls included serum bilirubin, SGOT, SGPT, vitamin B_{12}, prothrombin, alkaline phosphatase, cholesterol, albumin, globulin, Australia antigen, and antibody. Liver biopsies were performed in 14 patients and autopsies were done in 4 cases. Liver antigens were found in the unconcentrated urine of 4 of 42 patients with liver disease. There was no correlation between the presence or absence of liver antigens in the urine and the degree of liver function impairment. Nor was there a correlation with the duration or nature of the liver disease. Liver biopsies obtained at the time of urine sampling disclosed a significant difference between the five patients with negative urine and the three patients with positive urine. There was also a difference in the rate of mortality between antigen excretors and nonexcretors. Three of 38 patients with negative urine died; 2 with post-hepatitic cirrhosis died of massive gastrointestinal hemorrhage, and 1 with drug induced liver injury died of hepatic coma. Of the four antigen excretors, two succumbed to acute hepatic failure and the third, a cirrhotic patient, died of uremia due to proliferative glomerulonephritis. The results show that some patients with hepatic diseases excrete liver antigens in the urine. The number of antigen excretors disclosed was small and the urine of most patients, including those with severe jaundice and high SGOT levels, was negative. The presence of hepatic antigens correlated with parenchymal necrosis and was associated with a high mortality.

2812 STUDIES ON BILIARY BILE ACID METABOLISM IN HEPATO-BILIARY DISEASES. (Eng.)

Harada, T. (Dokkyo Univ. Sch. Medicine, Mibu, Shimotsuga, Tochigi Pref., 321-02 Japan). *Gastroenterol. Jpn.* 10(2):174-178; 1975.

Biliary bile acids were analyzed by thin-layer chromatography in 73 patients with various hepatobiliary diseases and in 12 patients without liver disease. The bile acids were divided into four types of glycine- and taurine-conjugates. The composition of biliary bile acid was different according to the degree of hepatic impairment, and the ratio of glycine-conjugate to taurine-conjugate (G/T ratio) was decreased in chronic liver diseases. The G/T ratio was 1.49 in the patients without liver disease, but it was 0.96 in the 11 patients with severe liver cirrhosis, and 1.38 in the 16 patients with chronic active hepatitis. In the three patient with acute hepatitis, the G/T ratio was low during the initial stage of the diseases, and it returned to a normal range upon recovery. There was also a decrease in the ratio of dihydroxycholic to cholic acid of biliary bile acid in patients with chronic liver diseases. It is concluded that the measuremen of bile acid in bile is valuable in the diagnosis of hepatic impairment.

2813 SERUM LEVELS OF C3 AND CHOLINESTERASE IN VARIOUS DISEASES OF THE LIVER. (Eng.)

Jorge, A. D.; Sanchez, D. (Internal Medicine Univ. Cuyo, Mendoza, Argentina). *Acta Hepatogastroenterol (Stuttg.)* 23(1):19-25; 1976.

The levels of complement fraction 3 (C 3), cholinesterase, albumin, and prothrombin were determined in 46 patients: 26 with liver cirrhosis, 9 with acute hepatitis, 6 with chronic aggressive hepatitis, 1 with chronic persistent hepatitis, and 4 with fatty liver. In all patients, and, particularl in those with cirrhotic liver, it was shown that the normal or pathological level of serum C 3 was related both qualitatively and quantitatively to the normal or pathological levels of cholinesterase, albumin, and prothrombin. The percentage in which the levels of these four parameters were pathologica was considerably higher in the cases with hepatic coma than in the cases without hepatic coma. The determination of the range of confidence for the four parameters showed that, in the patients with hepatic coma, cholinesterase reacted most sensitivel to liver damage (0.5-0.94) followed by C 3 and prothrombin (0.33-0.81). In cases without hepatic coma, cholinesterase was the most sensitive indicator (0.05-0.29), followed by prothrombin (0.03-0.24), albumin, and C 3 (0.00-0.16).

2814 PHENAZONE METABOLISM IN PATIENTS WITH LIVER DISEASE. (Eng.)

Andreasen, P. B.; Greisen, G. (Rigshospitalet, DK-2100 Copenhagen, Denmark). *Eur. J. Clin. Invest.* 6(1):21-26; 1976.

Phenazone metabolism was studied in 14 patients with liver disease (8 patients with cryptogenic or alcoholic cirrhosis, 2 patients with acute type A viral hepatitis, and 4 patients with drug-induced hepatitis), and in 6 normal volunteers. Phenazone (100 mg/ml) was administered i.v. over a period of 5 min at 15 mg/kg. In the controls, venous blood was drawn at 3, 4, 5, 7, 10, 13, and 24 hr after injection; in the patients, samples were drawn 3, 6, 9, 12, 24, and 48 hr after injection. In controls, urine was collected from 0-3, 3-6, 9-12, and 12-24 hr following administration; in the patients the periods were 0-24, 24-48, 48-72, and 72-96 hr. Phenazone and 4-hydroxyphenazone were determined by a gas-chromatographic method. The plasma and renal clearance of phenazone and the 4-hydroxyphenazone excretion in urine was significantly decreased in the patients with liver disease. The urinary excretion of 4-hydroxyphenazone was significantly correlated to the plasma clearance of phenazone ($r=+0.95$, $p<0.001$), to quantitative liver function as measured by the galactose elimination capacity ($r=+0.95$, $p<0.001$), and to the prothrombin values ($r=+0.82$, $p<0.001$). The determination of the 4-hydroxyphenazone excretion in urine may be used as an easy and noninvasive test of quantitative liver function.

2815 ASYMPTOMATIC LIVER DISEASE IN HAEMOPHILIACS.

(Eng.) Mannucci, P. M.; Capitanio, A.; Del Ninno, E.; Colombo, M.; Pareti, F.; Ruggeri, Z. M. (Via Pace 15, 20122 Milano, Italy). *J. Clin. Pathol.* 28(8):620-624; 1975.

The incidence of jaundice and of abnormal liver function tests was assessed in 75 patients with severe hemophilia A and in 16 patients with severe hemophilia B all of whom received multiple transfusion. Tests of hepatocyte function were within the normal range in the majority of patients. On physical examination, only five showed mild to moderate liver enlargement and two had hepatosplenomegaly. However, biliary cell function, liver cell damage, and bromsulphthalein retention tests gave high rates of abnormal values, which tended to increase with age. Hepatitis B surface antigen was present in seven patients and the corresponding antibody in 59 cases; 16 patients (14 with hemophilia A, 2 with hemophilia B) had a history of jaundice. All patients were asymptomatic, and only a minority showed clinical signs of liver involvement. These data suggest that in hemophiliacs, repeated and prolonged contact with the agent(s) responsible for posttransfusion hepatitis may cause chronic liver damage not associated with overt illness.

2816 LIVER DISEASE IN ALPHA$_1$-ANTITRYPSIN DEFICIENCY DETECTED BY SCREENING OF 200,000 INFANTS.

(Eng.) Sveger, T. (Malmo General Hosp., S-214 01 Malmo, Sweden). *N. Engl. J. Med.* 294(24):1316-1321; 1976.

The frequency and clinical characteristics of α_1-antitrypsin deficiency were studied prospectively in 200,000 newborn babies. One hundred and twenty Pi Z, 48 Pi SZ, 2 Pi Z-, and 1 Pi S-intants were identified and followed to the age of 6 months. Fourteen of 120 Pi Z infants had prolonged obstructive jaundice, nine with severe clinical and laboratory evidence of liver disease. Five had only laboratory evidence of liver disease. Eight other Pi Z infants had minimal abnormalities in serum bilirubin and hepatic enzyme activity and variable hepatosplenomegaly. All 22 Pi Z infants with hepatic abnormalities, two-thirds of whom were male, appeared healthy at 6 months of age. Ninety-eight Pi Z infants did not have clinical liver disease, but liver-function tests gave abnormal results in 44 of 84 at 3 months, and in 36 of 60 at 6 months of age. The number of infants who were small for their gestational age was greater ($p<0.001$) among those with clinical liver disease. None of the 48 Pi SZ infants had clinical liver disease, but 10 of 42 at 3 months and 1 of 22 at 6 months of age had abnormal liver function. The Pi Z and Pi SZ phenotypes are associated with covert or readily apparent hepatic dysfunction in the first 3 months of life. It is suggested that a level of α_1-antitrypsin above 40% of the normal one is of vital importance in protecting the liver tissue.

2817 HISTOPATHOLOGICAL STUDIES ON INTRAHEPATIC BILE DUCTS IN THE VICINITY OF PORTA HEPATIS IN BILIARY ATRESIA.

(Eng.) Chiba, T.; Kasai, M.; Sasano, N. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(3):199-207; 1976.

The pattern of bile ducts passing through the porta hepatis in biliary atresia was determined by histological examination of nine autopsy cases. Two types of bile ducts in the region of porta hepatis were distinguished. One group of patients had bile ducts with a large lumen connected with the extrahepatic duct; this pattern was seen in two cases of correctable type biliary atresia (I_a). The other pattern was achieved by many small bile ducts presumably originating from large lobular or segmental bile ducts. They usually measured less than 40 microns in diameter, and were lined by columnar epithelium. This pattern was observed in six cases of non-correctable type biliary atresia. In another case, there were several large bile ducts associated with many small ones. These large bile ducts were probably produced by rapid growth of ducts due to active bile flow after operation, because visible bile ducts were not found at porta hepatis during operation. Cholangitis may also affect the histologic findings of bile ducts at the porta hepatis. It is suggested that the patterns of bile ducts may be modified by some exogenous factors such as postoperative bile flow and ascending cholangitis.

2818 CHOLESTASIS IN INFANCY: STATUS REPORT AND CONCEPTUAL APPROACH.

(Eng.) Javitt, N. B. (New York Hosp.-Cornell Medical Center, New York, NY). *Gastroenterology* 70(6):1172-1181; 1976.

Disturbances in bile flow that occur early in life are reviewed. Cholestasis may result from anatomic or functional abnormalities. Causes of the former include extrahepatic biliary atresia and choledochal cysts. Functional abnormalities may be caused by primary bile secretory failure or secondary failure. Causes of the former include persistent intrahepatic cholestasis (familial and nonfamilial types) and recurrent cholestasis. Secondary bile secretory failure may result from infection, cystic fibrosis, anatomic abnormalities of the gastrointestinal tract, metabolic errors, and α-1-antitrypsin deficiency. Effective therapy depends upon distinguishing between anatomic and physiological abnormalities. In cholestasis with patent bile ducts, medical therapy attempts to increase canalicular bile flow, and mechanisms of increasing bile acid-dependent flow and bile acid-independent flow are discussed. The role of surgery in the management of cholestatic syndromes with patent bile ducts is considered from both the diagnostic and therapeutic viewpoints. When the problem is correctly identified, it is suggested that early diagnosis and medical therapy will prove more efficacious than surgery.

2819 BILE SALT GLUCURONIDES: IDENTIFICATION AND QUANTITATIVE ANALYSIS IN THE URINE OF PATIENTS WITH CHOLESTASIS.

(Eng.) Frohling, W.; Stiehl, A. (Medizinische Universitatsklinik, Bergheimer Strasse 58, D-6900 Heidelberg, W. Germany). *Eur. J. Clin. Invest.* 6(1):67-74; 1976.

Glucuronides of lithocholate, chenodeoxycholate, and cholate were synthesized enzymatically and characterized by thin layer chromatography, column chromatography, and specific enzymatic hydrolysis. Bile salt glucuronides were quantitatively analyzed in the urine of 10 patients with intra- and 10 patients with extra-hepatic cholestasis and were found to be present in 19 patients. The patients with intrahepatic cholestasis excreted 8.9 mg nonsulfated and nonglucuronidated bile salts, 18.2 mg sulfated bile salts, and 7.2 mg glucuronidated bile salts. The patients with extrahepatic cholestasis excreted 14.7 mg nonsulfated and nonglucuronidated bile salts, 20.7 mg sulfated bile salts, and 4.7 mg glucuronidated bile salts. In five healthy subjects, only trace amounts of bile salt glucuronides were detected. The findings indicate that glucuronidation of bile salts occurs in man and represents a metabolic pathway in patients with cholestasis.

2820 TREATMENT OF PRURITUS IN CHOLESTASIS OF PREGNANCY WITH A NEW ANION EXCHANGE RESIN (SECHOLEX).

(Eng.) Samsioe, G.; Johnson, P.; Gustafson, A. (Sahlgren's Hosp., Univ. Goteborg, Goteborg, Sweden). *Acta Obstet. Gynecol. Scand.* 54(4):333-340; 1975.

A new bile acid sequestrant poly-2(diethylamino)-ethyl) polyglycerylene dextran hydrochloride (PDX chloride, Secholex) was evaluated for the relief of pruritus in cholestasis of pregnancy (CP) in 31 women. CP was verified by the presence of abnormal lipoprotein X in serum. The clinical series was divided into two degrees of severity based on liver function tests, pruritus gravidarum (PG, 14 patients) and hepatosis of pregnancy (HP, 17 patents). Eleven of 31 women discontinued treatment because of gastrointestinal side effects. Of the 20 women continuing the study for more than 1 week, all with a milder form of cholestasis, PG (8 patients), experienced relief of pruritus, while some relief was obtained in 75% of the women with HP. In women with HP, serum alkaline phosphatase increased by 35% ($p<0.05$) after 4 weeks, while Simplastin A values fell concomitantly ($p<0.05$). In HP, serum cholesterol decreased by 10% ($p<0.05$) after 1 week of PDX chloride administration, but, thereafter, it tended to rise again. LP-X levels were lower ($p<0.05$) in the women with HP treated with PDX chloride for 4 weeks. In six patients the serum concentration of folic acid decreased ($p<0.05$) after 4 weeks of treatment. After 2 weeks of treatment, there was a higher 16:0 palmitic acid and a lower 18:0 stearic acid relative (and absolute) fatty acid content of serum lecithin. There was no effect on the essential fatty acids, 18:2 (linoleic acid) and 20:4 (arachidonic acid). An expected reduction in serum cholesterol levels, which are characteristically increased in CP, was not achieved by the administration of PDX chloride. Its effect on the fatty acid composition of serum lecithin suggests that it influences the basic defect of CP.

2821 HEPATIC GRANULOMAS IN LEPROSY: THEIR RELATION TO BACTEREMIA.

(Eng.) Chen, T. S. N.; Drutz, D. J.; Whelan, G. E. (Veterans Admin. Hosp., East Orange, NJ 07019). *Arch. Pathol. Lab. Med.* 100(4):182-185; 1976.

The clinicopathologic spectrum of hepatic involvement in various stages of leprosy and the relationship of bacteremia to the occurrence of hepatic granuloma were studied in 28 patients with leprosy. Of these patients, 12 had lepromatous (LL) leprosy, 6 had LL leprosy with erythema nodosum leprosum (ENL), 2 had borderline lepromatous (BL) leprosy, 3 had borderline (BB) leprosy, and 5 had borderline tuberculoid (BT) leprosy. None of the patients exhibited signs or symptoms of liver disease (jaundice, hepatomegaly, ascites, portal hypertension, or hepatic encephalopathic features), except for one patient with LL leprosy and ENL who concurrently contracted serum hepatitis. Hepatic dysfunction was absent, except for delayed BSP clearance (<10% retention) in 5 of 11 patients with LL leprosy, in 6 of 6 patients with LL leprosy and ENL, in 1 of 3 patients with BB leprosy, and in 1 of 5 patients with BT leprosy. Seven of 24 patients (5 with LL leprosy) were positive for hepatitis B surface antigen (HBsAg). Elevated titer for HBsAg antibody was found in two patients. Forty-one liver biopsies in the 28 patients confirmed that 21 had hepatic granulomas: 1 of 5 with BT, 2 of 3 with BB, 2 of 2 with BL, 10 of 12 with LL, and 6 of 6 with LL leprosy and ENL. The granulomas in BT leprosy were histiocytic in appearance. In BB leprosy, they were epithelioid and histiocytic. In BL leprosy, they were histiocytic and foam cell and in LL leprosy, or LL leprosy with ENL, all three types were found, although foam cell was most common. Epithelioid cell infiltrates were rimmed by lymphocytes, lacked caseation necrosis, and contained few or no acid-fast bacilli (AFB). This contrasted with the profusion of *Mycobacterium leprae* in foam cell lesions. Histiocytic lesions consisted of histiocytes clustered around swollen hepatocytes; AFB were absent. Hepatic granulomas increased in number as the mycobacterial infection intensified; *M. leprae* was found in 0 of 5 patients with BT, in 1 of 3 patients with BB, in 2 of 2 patients with BL, in 4 of 6 patients with LL leprosy with ENL, and in 9 of 12 patients with LL. AFB were seen in hepatic sinusoids and Kupffer cells in 13 of the 28 cases. Additional findings included mild to moderate fat in 11 patients, mild portal fibrosis in 9, mild focal necrosis and inflammation in 6, and the presence of glycogenated liver cell nuclei in 13 of 28 patients. Hepatic involvement varied with the severity of cutaneous infection and with the frequency and intensity of bacteremia. It is estimated that 1,000-10,000 AFB per milliliter of blood are required to generate the hepatic infiltrates.

2822 MALIGNANT HEPATOMA ASSOCIATED WITH ACQUIRED HEPATIC CUTANEOUS PORPHYRIA. (Eng.)

Keczkes, K.; Barker, D. J. (Hull Royal Infirmary, Hull, HO3 2JZ, England). *Arch. Dermatol.* 112(1): 78-82; 1976.

The case of a 60-yr-old woman with a 3-yr history of acquired hepatic cutaneous porphyria is presented. The patient presented with the characteristic cutaneous manifestations such as hyperpigmentation, photosensitivity, excessive blistering of hands and fingers, and hypertrichosis; these lesions were aggravated by exposure to sunlight. The patient did not have elevated urinary levels of porphyrin; however, fecal levels were elevated. Although a nonresectable hepatoma of low-grade malignancy was discovered in the right lobe of the liver, liver function was not altered. The patient was treated with fluorouracil (total of 13.25 g) perfused through a hepatic artery catheter. The treatment did not affect fecal levels of porphyrin, but the patient was ambulatory, 1 yr after beginning treatment. It is concluded that surgical removal of the primary hepatic tumor should be the first choice of treatment, when possible, but that infusion with fluorouracil prolongs life and causes little discomfort and few side-effects.

2823 EVALUATION OF THE LIGATION OF THE HEPATIC ARTERY AND REGIONAL ARTERIAL CHEMOTHERAPY IN THE TREATMENT OF PRIMARY AND SECONDARY CANCER OF THE LIVER. (Eng.)

Mokka, R. E. M.; Larmi, T. K. I.; Huttunen, R.; Kairaluoma, M. I. (Univ. Central Hosp., SF-90220 Oulu 22, Finland). *Ann. Chir. Gynaecol. Fenn.* 64(6):347-352; 1975.

The use of hepatic artery ligation and regional arterial chemotherapy in the treatment of primary and secondary liver cancer was evaluated in 23 patients; 12 of these patients underwent hepatic artery catheterization, and 5 were also given regional arterial chemotherapy with 5-fluorouracil beginning 2 days after ligation. The survival time correlated well with the amount of tumor tissue in the liver. Ligation of the hepatic artery prolonged the survival time of the operated patients, when compared with 15 untreated patients, and it also yielded good palliation. The hospital mortality was 13%. Three of the surviving patients were treated with ligation only, and their survival time was apparently longer than that for those treated simultaneously with chemotherapy. It is concluded that ligation of the hepatic artery is a valuable adjunct to the palliative treatment of malignant liver tumors. In selected cases, liver resection, 2-4 months after ligation yields the best and most longlasting palliation.

2824 CYTOLOGY AND CYTOGENESIS OF NEOPLASTIC (HYPERPLASTIC) HEPATIC NODULES. (Eng.)

Bannasch, P. (Institut fur Experimentelle Pathologie am Deutschen Krebsforschungszentrum, 69-Heidelberg, Im Neuenheimer Feld 280, W. Germany). *Cancer Res.* 36(7):2555-2562; 1976.

Information concerning the cytology and cytogenesis of neoplastic hepatic nodules is reviewed. Cytochemical and electron microscopic investigations of neoplastic nodules, induced in the rat liver by nitrosomorpholine or thioacetamide, show that most neoplastic nodules are comprised of a heterogeneous cell population. At least four different types of altered hepatocytes can be distinguished: "clear" glycogen storage cells with a dislocation and reduction of the granular endoplasmic reticulum, "acidophilic" glycogen storage cells with a hypertrophy of the agranular endoplasmic reticulum, fat-storing cells, and basophilic cells deficient in glycogen and rich in ribosomes. In addition, there are diverse intermediate cell types. The cytochemically demonstrable activity of glucose-6-phosphatase is reduced in most neoplastic nodules, but it may also be normal or even increased. The clear and the acidophilic cells precede the development of the neoplastic nodules by weeks and months. They usually form foci, which are taken to be preneoplastic lesions. During the formation of neoplastic nodules and hepatocellular carcinomas originating from such foci, the glycogen of the clear and the acidophilic cells is progressively reduced, whereas the number of ribosomes (basophilia) increases. This process, which may be accompanied by a transitory accumulation of fat, leads to the evolution of basophilic carcinoma cells. It is concluded that the majority of the neoplastic nodules consist of a mixture of precancerous, definitely cancerous, and diverse intermediate cells. Neoplastic nodules in which basophilic cells prevail may already be carcinomas. Although the neoplastic nodules seem to be a frequent precursor of hepatocellular carcinomas, the latter may also develop without going through the nodule stage.

2825 STUDIES ON THE PATHOPHYSIOLOGY OF ENCEPHALOPATHY IN REYE'S SYNDROME: HYPERAMMONEMIA IN REYE'S SYNDROME. (Eng.)

Shannon, D. C.; De Long, R.; Bercu, B.; Glick, T.; Herrin, J. T.; Moylan, F. M. B.; Todres, I. D. (Massachusetts General Hosp., Boston, MA 02114). *Pediatrics* 56(6):999-1004; 1975.

Acid-base relations in the blood and cerebrospinal fluid of 16 children with Reye's syndrome, 8 of whom survived, were compared. The initial acid-base status of the eight survivors was characterized by acute respiratory alkalosis (pCO_2= 32 mm Hg; HCO_3^-= 22.0 mEq/1), while that of the eight children who died was associated with metabolic acidosis as well (HCO_{3-}=10.0 mEq/1). Arterial-internal jugular venous ammonia concentration differences on day 1 (299 mg/100 ml) and day 2 (90 mg/100 ml) reflected cerebral uptake of ammonia while those on days 3 and 4 (-43 and -55 mg/100 ml) demonstrated cerebral release. Arterial blood hyperammonemia was detoxified safely in the brain as long as the levels did not exceed approximately 300 μg/100 ml. Beyond that level, lactic acidosis was observed, particularly in cerebral venous drainage. Arterial blood hyperammonemia was also related to the extent of alveolar hyperventilation. These findings are very similar to those seen in experimental hyperammonemia and support the concept that neurotoxicity in children with Reye's syndrome is at least partly due to impaired oxidative metabolism secondary to hyperammonemia.

2826 REYE SYNDROME WITH ASSOCIATED INFLUENZA A AND B INFECTION. (Eng.) Ruben, F. L.; Michaels, R. H. (Montefiore Hosp., 3459 Fifth Ave., Pittsburgh, PA 15213). *JAMA* 234(4):410-412; 1975.

Two groups of children treated for Reye's syndrome, 13 in 1974 and 6 in 1975, were studied for laboratory evidence of concomitant viral infection. Influenza B/Hong Kong was isolated from the pharynx in four of nine 1974 cases. One child had just recovered from varicella; adenovirus type 2 and respiratory syncytial virus were isolated from two additional patients. Serologic tests for influenza suggested concomitant or recent influenza B infection in 10 of the 13 cases. Influenza A/Port Chalmers was recovered from three of the six 1975 cases, and all six showed significant antibody rises to influenza A. It is suggested that influenza viruses provide a trigger mechanism for the development of Reye's syndrome in susceptible children.

2827 JUVENILE WILSON DISEASE: HISTOLOGIC AND FUNCTIONAL STUDIES DURING PENICILLAMINE THERAPY. (Eng.) Grand, R. J.; Vawter, G. F. (300 Longwood Ave., Boston, MA 02115). *J. Pediatr.* 87(6):1161-1170; 1975.

Seven patients who were being treated for juvenile Wilson's disease with penicillamine were studied 2-7 yr after the onset of drug treatment. All were without symptoms at follow-up. By comparison to initial biopsies (4 patients), post-treatment specimens showed either considerable reduction in portal fibrosis (2 patients) or no significant change (2 patients); portal inflammation and necrosis were greatly diminished or absent in three patients. Complete restitution of normal architecture was not seen in any of the patients. Three patients lacked initial biopsies. In these, portal cirrhosis, inflammation and necrosis, and fatty vacuolization of the hepatocytes were present 3, 5, and 7 yr after the onset of therapy. Lipofuscin pigment was abundant in follow-up biopsies. The data indicate that penicillamine produces clinical improvement and long-term survival in patients with Wilson's disease, when treatment is initiated early in the course of illness. In addition, it is concluded that morphologic improvement is achieved in some patients with Wilson's disease, following treatment with penicillamine, but that this is not predicted by biochemical factors. Sequential biopsies are necessary to evaluate completely the extent of healing.

2828 ALPHA-1 ANTITRYPSIN DEFICIENCY IN LIVER DISEASE. (Fre.) Brochard, C. (Hopital Franco-Musulman, 93009 Bobigny, France). *Sem. Hop. Paris* 51(15):1019-1024; 1975.

Literature on adult and childhood liver diseases caused by the congenital absence of the enzyme α-1-antitrypsin enzyme is reviewed. Histologically, PAS positive intracytoplasmic globules are present in the hepatocytes of patients with liver disease and are thought to result from an accumulation of the enzyme. The disease in infants appears initially as a neonatal jaundice, which progresses to cirrhosis and portal hypertension. α-1-Antitrypsin deficiency has also been reported in cases of adult hepatic diseases, frequently with pulmonary emphysema. In several cases, cirrhosis was discovered at autopsy after patients died of their pulmonary ailment. In adult or infant diseases, the cirrhosis is extremely variable and may be micro- or macronodular or fibrotic. Treatment with phenobarbital or estrogen has proven most effective.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

2855 BILIRUBIN SECRETION AND CONJUGATION IN THE CRIGLER-NAJJAR SYNDROME TYPE II. (Eng.) Gordon, E. R.; Shaffer, E. A.; Sass-Kortsak, A. (Division Gastroenterology, McGill Univ., Montreal, Canada). *Gastroenterology* 70(5):761-765; 1976.

Bilirubin secretion and conjugation was studied in a case of Crigler-Najjar syndrome (type II) in a 15-yr-old boy with severe congenital unconjugated hyperbilirubinemia. Bilirubin encephalopathy developed only during early puberty after surgery and fasting, coincident with a dramatic rise in serum bilirubin, which responded to intensive therapy. Fasting increased markedly the serum bilirubin levels and, probably was a major factor in precipitating the initial acute event. One year later, while the patient was in a metabolic steady state, the secretion rate of bilirubin was measured by a duodenal marker-perfusion technique, and the nature of the secreted bilirubin conjugates was characterized. Total bilirubin secretion rates were low, 4.39 mg/hr and 4.44 mg/hr on two separate studies. The major pigment detected in bile was bilirubin monoglucuronide. Bilirubin diglucuronide comprised only a minor fraction of the pigments, and other conjugates were not detected. The results document a reduced biliary bilirubin secretion and suggest that the addition of the second glucuronic acid moiety to the bilirubin molecule may be defective in Crigler-Najjar syndrome (type II).

2856 THE EFFECT OF REPEATED PHLEBOTOMY ON BILIRUBIN TURNOVER, BILIRUBIN CLEARANCE AND UNCONJUGATED HYPERBILIRUBINAEMIA IN THE CRIGLER-NAJJAR SYNDROME AND THE JAUNDICED GUNN RAT: APPLICATION OF COMPUTERS TO EXPERIMENTAL DESIGN. (Eng.) Berk, P. D.; Scharschmidt, B. F.; Waggoner, J. G.; White, S. C. (Building 10, Room 4D-52, Natl. Inst. Health, Bethesda, MD 20014). *Clin. Sci. Mol. Med.* 50(5): 333-348; 1976.

A multicompartmental model of erythrokinetics and bilirubin production was developed to predict the consequences of chronic phlebotomy on daily bilirubin turnover. Control values for four physiological variables including bilirubin turnover were determined in a 20-yr-old woman with type 1 congenital nonhemolytic jaundice (Crigler-Najjar syndrome). With these base-line data, the model predicted the following changes during phlebotomy: a 34% fall in bilirubin turnover, a 240% increase in the hemoglobin content of bone marrow erythroid precursors, a 25% fall in the half-life of ^{51}Cr-labeled RBC, and a characteristic alteration of the RBC survival curve after labeling with [2-^{14}C]glycine. On the assumption that hepatic bilirubin clearance was independent of turnover and would therefore remain unchanged, a fall in plasma unconjugated bilirubin concentration during phlebotomy from 436 to 282 μmol/l was expected. The patient underwent phlebotomy (350 ml/week for 2 months, and 500 ml/week during an additional 3 months). Appropriate studies during phlebotomy confirmed each of the above predictions. Turnover fell by 31%. Plasma unconjugated bilirubin remained essentially unchanged. Analogous results were observed in phlebotomized jaundiced Gunn rats. Kinetic studies in both the patient and the rats demonstrated that the failure of plasma unconjugated bilirubin to fall in parallel with bilirubin turnover resulted from a prolongation of the terminal half-life of radioactively labeled bilirubin and a fall in bilirubin clearance in every instance. These studies indicate that in congenital nonhemolytic jaundice, bilirubin clearance is uniquely influenced by bilirubin turnover, and that compartmental modeling and kinetic studies are useful for predicting and interpreting the results of both physiological experiments and experimental therapeutic regimens.

2857 COPROPORPHYRIN ISOMERS IN DUBIN-JOHNSON SYNDROME. (Eng.) Kondo, T.; Kuchiba, K.; Shimizu, Y. (Uwajima City Hosp., Uwajima City, Ehime, Japan). *Gastroenterology* 70(6):1117-1120; 1976.

To study abnormal porphyrin metabolism in Dubin-Johnson syndrome (DJS), coproporphyrin isomer distribution in urine and bile was investigated in 27 carriers, and in 29 patients with DJS. Urinary total coproporphyrin content in patients with DJS exceeded that of 23 normal controls ($p<0.01$). However, the increase in urinary excretion of total coproporphyrin was of a much lesser degree compared with an increase in urinary total coproporphyrin reported for erythropoietic porphyria in which a deficiency of uroporphyrinogen III cosynthetase was demonstrated. Urinary total coproporphyrin content in carriers was significantly less than that of normal controls ($p< 0.05$). This paradoxical decrease of urinary total coproporphyrin concentration in DJS carriers was observed in consequence of a decrease in coproporphyrin III excretion without concomitant increase in type I isomer. Administration of griseofulvin, in the dose that had been shown to precipitate attacks of acute porphyria in susceptible subjects (0.5-0.75 g, 7 days), to two carriers and four patients with DJS, did not elicit clinical signs suggestive of porphyria; urinary total coproporphyrin concentration and the percentage of coproporphyrin I remained unchanged. These results demonstrate an aspect of DJS that is not consistent with the hypothesis that a partial defect in uroporphyrinogen III cosynthetase of the liver may be the cause of DJS. Coproporphyrin in the bile of DJS patients was preponderantly type I.

2858 BILIARY EXCRETION OF CONJUGATED SULFOBROMOPHTHALEIN (BSP) IN CONSTITUTIONAL CONJUGATED HYPERBILIRUBINEMIAS. (Eng.) Abe, H.; Okuda, K. (Kurume Univ. Sch. Medicine, Kurume, Japan). *Digestion* 13(5):272-283; 1975.

BSP and its three major conjugates were determined in bile or duodenal aspirate, plasma, and urine following i.v. administration of free BSP (5 mg/kg) and synthetic BSP-glutathione (BSP-GSH, 6.8 mg) in five patients with the Dubin-Johnson syndrome and in two patients with the Rotor syndrome, using alumina column chromatography. In Dubin-Johnson patients, the biliary excretion of conjugated BSP was selectively impaired; conjugated BSP increased in plasma, replacing free BSP after 30 min, and plasma retention of BSP-GSH was greater than that of free BSP when administered i.v. In contrast, biliary excretion of BSP and its conjugates was not impaired, and regurgitation of conjugated BSP into plasma was minimal in the Rotor syndrome. Thus, these two constitutional hyperbilirubinemias can be distinguished by their basic defects in BSP metabolism.

2859 BREAST MILK JAUNDICE: IN VITRO INHIBITION OF RAT LIVER BILIRUBIN-URIDINE DIPHOSPHATE GLUCURONYLTRANSFERASE ACTIVITY AND Z PROTEIN-BROMOSULFOPHTHALEIN BINDING BY HUMAN BREAST MILK. (Eng.) Foliot, A.; Ploussard, J. P.; Housset, E.; Christoforov, B.; Luzeau, R.; Odievre, M. (Unite de Recherches de Biologie Animale et Techniques Experimentales, INSERM, Paris, France.) *Pediatr. Res.* 10(6):594-598; 1976.

Twenty-four samples of breast milk from nine mothers of infants with breast milk jaundice were studied to determine their ability to inhibit bilirubin conjugation and BSP binding to hepatic Z and Y protein in Sprague-Dawley rat liver homogenates. Eight samples of milk from mothers of nonjaundiced infants and five formula milks enriched with polyunsaturated fatty acids served as controls. Milk from mothers with jaundiced infants was able to inhibit bilirubin conjugation *in vitro* as well as BSP binding to hepatic Z protein, whereas the controls were not. The inhibitory activity was maximal after storage at 4 C for 96 hr and it was destroyed by heating at 56 C for 15 min. Under these conditions, bilirubin conjugation was inhibited by 80.3%, and BSP binding to Z protein was inhibited by 82.1%. There was no effect on BSP binding to Y protein. Pathologic breast milk inhibited BSP-Z protein binding only when stored under conditions that also caused bilirubin conjugation inhibition *in vitro* as well as the liberation of nonesterified fatty acids. Thus, the appearance of this inhibitory capacity *in vitro* seems to be linked to the lipolytic activity particular to pathologic milks.

2860 DUBIN-JOHNSON SYNDROME: REPORT OF TWO CASES. (Spa.) Andres, A. G.; Megias, A. P.; Maillo, G. A.; Moya, J. E. (Residencia Sanitaria de la S. S. "20 de Noviembre," Alicante, Spain). *Rev. Esp. Enferm. Apar. Dig.* 46(5):553-558; 1975.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

2864 CHLORPROPAMIDE-INDUCED GRANULOMAS: A PROBABLE HYPERSENSITIVITY REACTION IN LIVER AND BONE MARROW. (Eng.) Rigberg, L. A.; Robinson, M. J.; Espiritu, C. R. (Mt. Sinai Medical Center, 4300 Alton Rd., Miami Beach, FL 33140). *JAMA* 235(4):409-410; 1976.

The case report of a diabetic patient who developed anicteric hepatitis, associated with fever and exfoliative dermatitis, 2 weeks after intake of a long-acting sulfonylurea, chlorpropamide (Diabinese) is presented. Granulomas showing heavy infiltration with eosinophils were found in the liver and bone marrow. These were interpreted as manifestations of an allergic reaction. The clinical signs, abnormal laboratory findings, and hepatic lesions subsided spontaneously on withdrawal of the drug; however, bone marrow changes persisted 7 months after cessation of the drug. This is thought to be the first report of a patient with liver and bone marrow inflammation characterized by granulomas with eosinophilic infiltration following intake of chlorpropamide.

2865 DIPHENYLHYDANTOIN-INDUCED HEPATIC NECROSIS: A CASE STUDY. (Eng.) Lee, T. J.; Carney, C. N.; Lapis, J. L.; Higgins, T.; Fallon, H. J. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514). *Gastroenterology* 70(3):422-424; 1976.

The case of a 21-yr-old woman with diphenylhydantoin (DPH)-induced hepatic necrosis is presented and is compared with similar case studies. The patient received DPH and phenobarbital treatment for post-traumatic seizure for 18 months before presentation with malaise and progressive weakness. One week after hospitalization, during which time the patient was receiving 100 mg of DPH (3 times/day) and 100 mg phenobarbital (3 times/day), she developed lymphadenopathy, fever, exfoliative dermatitis, and hepatic failure. The patient died in hepatic coma, and autopsy disclosed massive hepatic necrosis. It is concluded that studies of liver function are indicated in patients who receive DPH to assess the true incidence of hepatocellular injury.

2866 HALOTHANE-INDUCED LIVER DAMAGE: AN ANALYSIS OF THE MATERIAL REPORTED TO THE SWEDISH ADVERSE DRUG REACTION COMMITTEE, 1966-1973. (Eng.) Bottiger, L. E.; Dalen, E.; Hallen, B. (Karolinska Hosp., S-104 01 Stockholm, Sweden). *Acta Anaesthesiol. Scand.* 20(1):40-46; 1976.

An analysis was made of 94 patients who developed liver injury following surgery and halothane anesthesia over an 8-yr period. Thirteen of the 94 patients died. Seventy-five percent of all patients and 12 of the 13 fatal cases experienced at least one halothane exposure previous to the one under analysis. Of the 83 patients for whom such information was available, only 15 were anesthesized for more than 2 hr. The interval between halothane anesthesia and the appearance of fever was almost 7 days after a single exposure, but was reduced to 4 days after multiple exposures. Corresponding figures for the appearance of jaundice were 8 and 7 days, resp. Halothane hepatitis was more common in older patients. The results indicate that halothane administration causes a drug-induced type of hepatitis, an allergic manifestation, representing acquired hypersensitivity. The type and duration of the surgical intervention in these cases was uncharacteristic and did not include a large number of upper abdominal operations, which are known to carry an increased risk of hepatic damage. No patient had prolonged hypotension. The number receiving blood transfusions was small, and the interval between transfusion and the onset of hepatic disease, in all instances, was too short to seriously consider serum hepatitis. It is not suggested that the use of halothane be withheld, but rather that the drug should not be used indiscriminately as liver injury becomes more severe following repeated exposures.

2867 SERUM FERRITIN LEVELS IN ACUTE HEPATOCELLULAR DAMAGE FROM PARACETAMOL OVERDOSAGE. (Eng.) Eastham, E. J.; Bell, J. I.; Douglas, A. P. (Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, U.K.). *Br. Med. J.* 1(6012):750-751; 1976.

Serum ferritin levels were measured in 25 patients who had taken an overdose of paracetamol within the preceding 18 hr, and the correlation between these levels, transaminase, and degree of hepatocellular damage (as determined by biopsy) was examined. Eight patients with mild and one patient with moderate liver damage had normal levels of serum aspartate aminotransferase (SGOT, 4-20 IU); eight of these patients attained serum ferritin levels that were significantly increased from the initial value by the third day of hospitalization. Seven patients with moderate and one with mild liver damage had increased SGOT (<400 IU), and ferritin levels were elevated by the third day in six patients. The eight remaining patients had severe liver damage, SGOT levels higher than 400 IU, and greatly increased ferritin (1,070->6,000 μg/l) by the third day. There was no overall correlation between ferritin and transaminase levels on the third day, but when the ferritin changes were expressed as a percentage of the initial values, a definite correlation emerged ($p<0.05$). Serum ferritin levels, in acute hepatocellular damage, correlate closely with pathological changes and are more sensitive than transaminase estimations.

2868 PIPERAZINE HEPATITIS. (Eng.) Hamlyn, A. N.; Morris, J. S.; Sarkany, I.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3, England). *Gastroenterology* 70(6):1144-1147; 1976.

The first reported case of a 25-yr-old woman who on two occasions developed an acute hepatitis reaction after piperazine administration is presented. Piperazine phosphate was prescribed for this patient for the treatment of threadworms. Malaise and vomiting developed 3 weeks later and jaundice occurred at the end of the 4th week. The patient was treated with i.v. dextrose, vitamin K, dietary protein restriction, and oral neomycin, resulting in the diappearance of confusion and a rise in Thrombotest. Prednisone (20 mg/day) was administered when the cholestasis persisted. After 2 weeks, serum bilirubin fell from 24 to 5 mg/dl. The patient was discharged with a presumptive diagnosis of resolving viral hepatitis. One year later, she was again given piperazine phosphate (4 g) for threadworm infestation, and again she experienced an acute reaction. Liver biopsy performed during each reaction showed changes of acute hepatitis that were more severe on the second occasion. The evidence favors a hypersensitivity mechanism rather than a direct toxic effect of piperazine or its metabolites on the liver. The humoral or cellular immune basis for such hypersensitivity has not yet been elucidated.

2869 QUINIDINE HYPERSENSITIVITY AND LIVER INVOLVEMENT: A SURVEY OF 32 PATIENTS. (Eng.)

Geltner, D.; Chajek, T.; Rubinger, D.; Levij, I. S. (Hadassah Univ. Hosp., P.O. Box 499, Jerusalem, Israel). *Gastroenterology* 70(5):650-652; 1976.

The case histories of 487 patients who received quinidine therapy were analyzed to determine the frequency of quinidine-induced liver disease. Thirty-two patients developed hypersensitivity reactions, and 10 of these patients had clinical and biochemical manifestations of liver involvement. All patients suffered from arteriosclerotic heart disease and received quinidine because of ventricular supraventricular arrhythmias. In 8 out of 10 patients, the symptomatology developed within 2 weeks of commencing quinidine treatment and in the other 2 cases, symptoms appeared only after 90 days and 180 days, resp. In four patients, liver biopsy showed granulomatous hepatitis. Clinical signs included fever (9), hepatomegaly (4), splenomegaly and lymphadenopathy (1), skin rash (2), and pruritus (1). Liver involvement was confirmed by liver function tests. Discontinuation of the drug resulted in disappearance of symptoms. The results suggest that quinidine-induced hepatitis is a relatively common side effect of this drug.

2870 QUINIDINE HEPATOTOXICITY. A REPORT OF A CASE AND REVIEW OF THE LITERATURE. (Eng.)

Koch, M. J.; Seeff, L. B.; Crumley, C. E.; Rabin, L.; Burns, W. A. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Gastroenterology* 70(6):1136-1140; 1976.

A case of presumed quinidine hepatotoxicity in a 47-yr-old man is presented. The patient was hospitalized complaining of palpitations, light-headedness, and a recent history of increased shortness of breath, dyspnea on exertion, and orthopnea. On the third day of hospitalization, quinidine sulfate (200 mg, p.o.) was given every 6 hr. After the third dose, it was stopped due to onset of diarrhea, but it was reinstituted on the sixth day. Ten days after the initial dose of quinidine, the patient developed chills, nausea, vomiting, and vague upper abdominal pain. On the 14th day, SGOT and SGPT levels were abnormal for the first time, and alkaline phosphatase was 210 mU/ml. On day 31, a percutaneous liver biopsy and electron microscopic studies revealed changes that were suggestive of drug-induced hepatitis. On day 35, all medications except digoxin were discontinued. SGPT peaked at 910 mU/ml and alkaline phosphatase at 210 mU/ml on day 36, then both declined rapidly as did the fever. Two months after discharge, the patient was challenged with quinidine sulfate (200 gm, p.o., 6 hr, 4 doses). At 32 hr after the last dose, he complained of discomfort, his temperature rose, as did the SGPT and SGOT levels. Transaminase values returned to normal at 103 hr after the last dose of quinidine. It is suggested that the development of unexplained fever within 1 month of quinidine administration should alert the physician to the possibility of a hepatotoxic reaction and should signal the need for appropriate evaluation.

2871 HISTOPATHOLOGY OF LIVER LESIONS ASSOCIATED WITH EXPOSURE TO VINYL CHLORIDE MONOMER.

(Eng.) Weinbren, K. (Royal Postgraduate Medical Sch., Du Cane Road, London, W12 OHS England). *Proc. R. Soc. Med.* 60(4):299-303; 1976.

Changes that occur in the liver of patients suffering from angiosarcoma and of patients who were exposed to vinyl chloride monomer but did not show evidence of tumor development are described. In general, tumors showed dark hemorrhagic nodules, cariable distortion and fibrosis of liver tissue, and necrosis. Three types of angiosarcoma were characterized: the sinusoidal pattern in which dilated hepatic sinusoids are lined by enlarged and proliferating tumor cells, with hepatocyte plates clearly recognizable between tumor cells; the papillary type in which papillary formations of tumor cells are borne on a core of connective tissue, which include surviving hepatocytes; and the cavernous type in which marked dilation of sinusoids are surrounded by thick fibrous walls lined by tumor cells. Generally, the tumor cell was distinguishable from hepatocytes; it resembled cells normally associated with vessel walls and also appears to be closely related to vascular spaces with variable degrees of abnormality. There were marked changes in other elements (especially the supporting stroma) in both tumor-free and tumor-bearing parts of the liver. These alterations range from minor increases in reticulin fibers to massive increases in collagen fibers, which obstruct the lumen. Fibrosis of the portal tracts was also noted. The relevance of nontumorous changes to the subsequent development of angiosarcoma must be resolved since many of the alterations appear in other conditions such as congestive cardiac failure, lymphomas, and other drug toxicity situations.

2872 TRAUMATIC LESIONS OF THE LIVER: THERAPEUTIC ASPECTS. (Por.)

Mendes de Almeida, J. M.; Palla Garcia, J. (Hospital de Arroios, Servico no. 2, Lisbon, Portugal). *Bol. Clin. Hosp. Civis Lisboa* 35(1/4):115-141; 1973-1974.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

2875 A RADIOIMMUNOASSAY TO DETERMINE THE SUBTYPES D AND Y OF THE HEPATITIS-B SURFACE ANTIGEN. (Eng.) Thamer, G.; Kommerell, B. (Gastroenterologische Abteilung der Medizinischen Klinik, 69 Heidelberg, Bergheimer Str. 58, West Germany). *J. Lab. Clin. Med.* 87(4):734-738; 1976.

A sensitive radioimmunologic test system for determining the subtypes D and Y of the hepatitis B surface antigen (HBsAg, Australia antigen, HAA) is described. The technique uses the immunoadsorption principle; the antigen to be subtyped is incubated with an antiserum containing ^{125}I-labeled antibodies to the antigenic determinants a, d, and y. The specificity of the antibody, which is not consumed in forming the antigen antibody complex, is determined by absorption on agarose. The HBsAg-containing serum to be subtyped is incubated in duplicate with antiserum for 24 hr at 24 C. Sepharose-HBsAg subtype D (Seph.-ad) and Sepharose-HBsAg subtype Y (Seph.-ay) are each added to one incubation, and are reincubated for 24 hr at 24 C. The incubates are subsequently transferred quantitatively into small columns, and the Sepharose-HBsAg complex is washed at pH 7.4. The activity bound to the Sepharose-HBsAg complexes in the columns is determined in the gamma counter. The quotient of the activities bound to the Sepharose-HBsAg complexes (c.p.m.-Seph.-ad/c.p.m.-Seph.-ay) was significantly lower ($p<0.005$) in determining the subtype D (1.01) than in determining the subtype Y (2.73). Thus, radioimmunoassay permits an unequivocal identification of HBsAg containing sera that had previously been subtyped. by conventional methods.

2876 BIOPHYSICAL AND BIOCHEMICAL PROPERTIES OF CR326 HUMAN HEPATITIS A VIRUS. (Eng.) Provost, P. J.; Wolanski, B. S.; Miller, W. J.; Ittensohn, O. L.; McAleer, W. J.; Hilleman, M. R. (Merck Inst. Therapeutic Res., West Point, PA 19486). *Am. J. Med. Sci.* 270(1):87-92; 1975.

A summary of the morphologic, physical, and chemical characteristics of CR326 human hepatitis A virus is presented. Electron microscopic examination of CR326 virus, purified by isopycnic banding from infected marmoset sera, revealed 27-mμ spherical particles. The particles were identified as hepatitis A virus by tests for infectivity and by specific neutralization of infectivity with convalescent human hepatitis A serum. Also, identical 27-mμ viruses in liver extracts gave specific reactions with hepatitis A antisera when tested by immune electron microscopy. The buoyant density of the virus in CsCl was 1.34 and it was heat (60 C), ether, and acid stable but it was destroyed by heat (100 C), formalin (1:4000), and UV irradiation. Electron microscopic studies of sections of infected marmoset liver showed intracytoplasmic virus particles, usually in vesicles. Presumptive findings for RNA, together with the intracytoplasmic location of the virus, indicated the virus to be of RNA-type. The characteristics of the virus indicate that it is closely related to the enterovirus family and not to hepatitis B virus.

2877 ANTIBODIES AGAINST HEPATITIS B (SURFACE) ANTIGEN IN PATIENTS WITH HEPATITIS AND OTHER GROUPS OF EPIDEMIOLOGIC INTEREST. (Ger.) Lange, W.; Apodaca, J.; Kohler, H. (Robert-Koch-Institut Berlin, D-1 Berlin 65, Nordufer 20, West Germany). *Zentralbl. Bakteriol. (Orig.A)* 232(2/3): 199-212; 1975.

Sera of patients with hepatitis A and B and of patients in a hemodialysis unit as well as sera of drug addicts were examined for the presence of antibodies against hepatitis B surface antigen (HBsAg) using the Ausab test, a new radioimmunoassay. In 79.3% of the hepatitis B patients, the occurrence of antibodies against HBsAg (anti-HBsAg) was noted after the HBsAg had disappeared. In hepatitis A patients, anti-HBsAg was detected in 15.5% of the adults and in 4.6% of the children. These antibodies persisted over an observation period of up to 15 months and were not connected with the apparent illness at the time of the examination. These results are an indication of the frequency of antibodies against HBsAg in the normal population. In two patients with hepatitis A, a delayed antibody reaction similar to that seen in hepatitis B patients was observed, though HBsAg was not detected (Ausria 125 test). It is assumed that these patients suffered from hepatitis B, which was diagnosed as hepatitis A on the basis of the negative HBsAg status. According to this observation, not all cases of HBsAg-negative hepatitis are necessarily type A, but are occasionally type B, which is not detectable by means of HBsAg assay at the time. Drug addicts without hepatitis at the time of investigation showed 50.8% anti-HBsAg; in 24.3%, HBsAg was detected by means of the Ausria 125 test. In 19 drug addicts with positive antigen or antibody status, a history of hepatitis was established. Patients in the hemodialysis unit were HBsAg carriers in 9.2% of cases, and 53.5% were anti-HBsAg carriers. The data obtained from drug addicts and dialysis patients point to a high risk of infection in both groups and to a frequent contact with HBsAg (booster) in dialysis units. The combined application of sensitive tests for the detection of antigen and antibodies (radioimmunoassays) with regard to epidemiological and anamnestic studies is recommended.

2878 STUDY OF THE EFFECT OF REST IN THE EVOLUTION OF VIRAL HEPATITIS.

(Fre.) Laverdant, C.; Cristau, P.; Essioux, H.; Molinie, C.; Gendron, Y.; Bernard, J.; Kassem, A. (Hopital Militaire Begin, 94160 Saint-Mande, France). *Sem. Hop. Paris* 51(15):1001-1007; 1975.

The therapeutic value of bed rest and restricted physical activity was studied in 214 servicemen with viral hepatitis who were hospitalized on days 1-4 after the appearance of jaundice. Of the group, 104 were returned to home base on days 11-13 with no restrictions. The remaining 110 were kept on bed rest except for meals and elimination until their urinary transaminase levels fell below 100 IU. Outdoor walks were permitted after approximately 29 days. Recovery was complete in all but 10 subjects on bed rest, while 23 of the group on full activity experienced relapse or persistence of disease. A retrospective study of another group of 51 subjects who experienced relapses on days 9-22 of hepatitis revealed that 24 had remained active during that period. A third study of 154 patients concluded that physical and intellectual activity or excessive eating and drinking do not have a negative effect on the course of viral hepatitis on days 30-60. It is concluded that physical activity be restricted until transaminase activity is normal (on about day 30). During this period resumption of work should definitely be prohibited.

2879 VIRAL HEPATITIS: RECENT DEVELOPMENTS AND PROSPECTS FOR PREVENTION.

(Eng.) Krugman, S. (550 First Ave., New York, NY 10016). *J. Pediatr.* 87(6):1067-1077; 1975.

Research on the etiologic, epidemiologic, immunologic, and prophylactic aspects of type A and type B hepatitis virus infection is reviewed. The hepatitis A virus was found to be a 27 nm particle with characteristics resembling an enterovirus. Hepatitis A infection was transmitted to marmosets and chimpanzees. In addition, specific complement fixation and immune adherence antibody tests for hepatitis A were developed. Recent advances in hepatitis B research include: (1) identification of the virus as a 42 nm particle (Dane particle) containing an outer coat, the hepatitis B surface antigen, and an inner core, the hepatitis B core antigen; (2) development of specific tests to detect the hepatitis B antigens and their respective antibodies; (3) transmission of the infection to chimpanzees; (4) development of a specific hepatitis B immune serum globulin; and (5) development of an inactivated hepatitis B vaccine.

2880 AN OUTBREAK OF TYPE B HEPATITIS ASSOCIATED WITH TRANSFUSION OF PLASMA PROTEIN FRACTION.

(Eng.) Pattison, C. P.; Klein, C. A.; Leger, R. T.; Maynard, J. E.; Berquist, K. R.; Hofnagle, J. H.; Barker, L. F.; Bryan, J. A.; Smith, D. E. (Center Disease Control, 4402 North 7th St., Phoenix, AZ 85014). *Am. J. Epidemiol.* 103(4):399-407; 1976.

An outbreak of type B hepatitis, at a 1200 bed hospital, following transfusion with a single lot (B) of plasma protein fraction (PPF) is described. Of 51 PPF recipients, 31 participated in the study and 19 (61%) had an illness compatible with hepatitis. Patients who had transfusions on the cardiovascular surgery service (CVS) were studied to examine the association between lot B and post transfusion hepatitis. This group included 19 of the 31 members of the study population, as well as a matched control group. None of the control patients developed clinical hepatitis as compared with 11 patients (58%) in the CVS study group who received lot B ($p<0.001$). Serological data from blood samples from 29 of the 31 members of the lot B study group showed evidence of prior infection with hepatitis B virus in 90% of the cases. These findings provided evidence that lot B was the vehicle for transmission of disease. Recipients of four other PPF lots from the same manufacturer were studied. Two of these lots were also associated with extremely high clinical hepatitis rates (45% and 55%). The other two lots, which were prepared from donor plasma, contributing to the composition of the initially studied PPF lot, failed to produce clinical illness, although one of these lots was associated with a high prevalence of hepatitis B seropositivity. It is suggested that heat treated PPF was involved in the transmission of type B hepatitis. Additional studies are required to determine the effects of pasteurization on inactivating hepatitis B virus.

2881 RECENT ADVANCES IN VIRAL HEPATITIS: PART I.

(Eng.) Melnick, J. L.; Hollinger, F. B.; Dreesman, G. R. (Baylor Coll. Medicine, Houston, TX 77030). *South. Med. J.* 69(4):468-475; 1976.

Recent advances in the understanding and clinical aspects of viral hepatitis are reviewed. The epidemiologic and clinical features of types A and B human hepatitis virus infections are compared, and the physicochemical properties of the two viruses are summarized. Either A or B virus infection can result in the most common histopathologic lesion, classical viral hepatitis. Subacute hepatic necrosis occurs in 5-15% of the cases, and it is more severe. Acute fulminant hepatitis is rare with type A (<0.1%), and it is uncommon in type B infections (1-3%). Cholestasis or chronic persistent hepatitis may complicate acute hepatitis, and chronic aggressive hepatitis occurs in 3-10% of cases of type B viral infection. Complete recovery occurs in most patients with type A and in 85% of those with type B. The persistence of hepatitis B antigen in the blood of a recovered patient represents a continual potential source of infection. Laboratory features and tests for infection are summarized, and the various means of demonstrating hepatitis B antigen are discussed. A single infection with virus of either type confers homologous but not heterologous protection against reinfection. The possible association between hepatitis and hepatoma, periarteritis nodosa, and chronic active hepatitis is noted.

2882 NORMAL DISPOSITION OF OXAZEPAM IN ACUTE VIRAL HEPATITIS AND CIRRHOSIS. (Eng.)

Shull, H. J., Jr.; Wilkinson, G. R.; Johnson, R.; Schenker, S. (Vanderbilt Univ. Sch. Medicine, Nashville, TN). *Ann. Intern. Med.* 84(4):420-425; 1976.

The effect of acute and chronic hepatic parenchymal disease on the elimination of oxazepam was investigated in seven patients with acute viral hepatitis, six patients with cirrhosis (men aged 37-57), and in age-matched control subjects (aged 14-84). All subjects received 45 mg oxazepam p.o. Unchanged oxazepam appeared rapidly in the plasma, reaching a maximum level after 2-4 hr. The peak concentration of total oxazepam, achieved at the same time or slightly later, was approximately 150-250% greater than the unchanged drug, and its concentration also decreased exponentially with a similar half-life to that of the total drug. These values are comparable to values obtained in age-matched controls ($p>0.05$). The older control group had a statistically larger apparent volume of distribution as assessed by Vd(β) ($p<0.02$) than the younger group, but such a difference was not apparent when the distribution space was estimated as Vd(extrap). The apparent distribution volume of oxazepam, its plasma binding, blood/plasma ratio, and rate of urinary excretion, predominantly as the glucuronide, were comparable ($p>0.05$) in the two groups of patients with liver disease and their respective controls. Unlike many other sedatives, oxazepam is eliminated normally in patients with parenchymal liver disease and, therefore, on pharmacokinetic grounds, it seems to be an excellent sedative for use in such persons.

2883 VIRAL HEPATITIS: A PATHOLOGIC SPECTRUM.

(Eng.) Peters, R. L. (Univ. Southern California Sch. Medicine, Los Angeles, CA 90007). *Am. J. Med. Sci.* 270(1):17-31; 1975.

Pathologic changes that provide difficulty in the application of the liver biopsy as a prognostic as well as diagnostic tool are discussed in relation to viral hepatitis. Three major classes of morphologic change associated with this disease are acute cytological damage, inflammatory reaction, and hepatocellular regeneration. Acute viral hepatitis shows a generalized but centrolobularly accentuated acute cell damage including poorly defined areas of hepatocytolysis occurring nearly simultaneously with a hyperplastic and exudative inflammatory reaction. Regeneration is recognizable by the time that symptoms appear. Variations in histologic patterns of acute viral hepatitis often result in an overdiagnosis of chronic liver disease. The most confusing morphologic characteristics are: unusual extent of necrosis, excessive inflammatory response, and increased amounts of collagen. Histologic changes in liver tissue of patients who have recovered from fulminant viral hepatitis illustrate the extreme examples of excessive necrosis from viral hepatitis that might be seen on liver biopsy. These cases do not progress characteristically to chronic hepatitis or cirrhosis. Diagnostic difficulties may occur in patients with altered immune responses or pre-existing liver disease. Except for older patients, those with severe necrotic changes during acute hepatitis do not usually develop severe sequelae of disease. Chronic active hepatitis is progressive and is characterized pathologically by changes in the distribution of necrosis and regeneration within the lobule. "Cobblestone" hepatocellular change resembling continuing regeneration, focal hepatocytolysis, and, frequently, portal lymphoid hyperplasia characterize persistent viral hepatitis. These features fade with time, and in type B persistent viral hepatitis, the incidence of "ground glass" cells with hepatitis B surface antigen increases. It is suggested that this may reflect a continued adaptation of host and virus to one another.

2884 HEPATITIS B ANTIGEN AND ANTIBODY IN THE U.S. ARMY: PREVALENCE IN HEALTH CARE PERSONNEL.

(Eng.) Segal, H. E.; Llewellyn, C. H.; Irwin, G.; Bancroft, W. H.; Boe, G. P.; Balaban, D. J. (Walter Reed Inst. Res., Washington, DC 20012). *Am. J. Public Health* 66(7):667-671; 1976.

A cohort of 5,443 military health care personnel was studied to determine the prevalence of hepatitis B antigen (HBsAg) and antibody (anti-HBs). Sera were tested for HBsAg by radioimmunoassay, and sera HBsAg-positive by counter-electrophoresis were subtyped. Antibody was determined by a passive hemagglutination test. Serologic evidence of hepatitis B infection (HBsAg or anti-HBs) was found in 270 personnel. Of 30 HBsAg-positive sera, 12 were subtypable; 10 were HBsAg/adw and 2 were HBsAg/ayw. In the 1,534 physicians, 849 dentists, and 1,370 nurses (all directly involved in patient care), there was a 5.8% rate of seropositivity, whereas in personnel who were involved in non-patient care, there was a 2.8% rate. Two hundred and three personnel reported a history of hepatitis, and 183 reported receiving a blood transfusion. A greater proportion of personnel with one or more months in surgical specialties were hepatitis B virus-positive than were those with one or more months in medical specialties (11.1% versus 8.1%). Of 1,255 personnel born in urban areas, 10 were HBsAg-positive, 60 were anti-HBs-positive, and 70 were hepatitis B virus-positive. Of 1,489 personnel from rural areas, the corresponding figures were 6, 56, and 62, resp., and for 85 personnel born in foreign countries, they were 3, 5, and 8, resp. Of personnel with previous overseas assignments, primarily non-patient case oriented officers who served in Southeast Asia, 9.6%

had serologic evidence of hepatitis B infection; 4.5% of personnel without prior overseas service had such evidence. These data present a composite of risk factors that are operative in the acquisition of hepatitis B seropositivity.

2885 HEPATITIS A AND B IN THE FAMILY UNIT: NONPARENTERAL TRANSMISSION BY ASYMPTOMATIC CHILDREN. (Eng.) Vernon, T. M.; Wright, R. A.; Kohler, P. F.; Merrill, D. A. (Colorado Dept. Health, 4210 E. 11th Ave., Denver, CO 80220). *JAMA* 235(26): 2829-2831; 1976.

An outbreak of hepatitis A in 12 members of 6 families in an organization for the adoption of Vietnamese children was investigated. Thirty-two of the organization's 37 families were studied. Only three of the hepatitis patients had contact with another hepatitis patient prior to the onset of illness. Ten of the 12 cases occurred among 40 family members who had close contact with the adopted children. Eighty-five members had either close or casual contact; all 12 cases occurred among these 85, while none occurred among 74 family members without contact ($p<0.01$). During and after the outbreak, 33 Vietnamese adoptees and 59 Americans (33 adults and 26 children) in 26 adopting families were tested for hepatitis B surface antigen (HBsAg) by electroimmunodiffusion and solid-phase radioimmunoassay and for anti-HBs by the passive hemagglutination technique employing HBsAg-coated RBC. Nine of the 33 Vietnamese were positive for HBsAg and 10 were positive for anti-HBs. None of the Americans was positive for HBsAg. Two of 33 adults were positive for anti-HBs, and 6 of the 26 American children were positive. The eight Americans with positive reactions for anti-HBs represented six families, all of whom had adopted a Vietnamese child. Five of the six antibody-positive American children had an HBsAg-positive Vietnamese child in their families at the time of serologic testing. It is concluded that hepatitis A was probably introduced into adopting families by the asymptomatic children. Thus, healthy orphans from high hepatitis incidence areas may transmit hepatitis B, as well aa hepatitis A, in the family unit.

2886 HB-ANTIGEN IN SERUM AND SYNOVITIS IN ACUTE HEPATITIS WITH AND WITHOUT POLYARTHRITIS. (Eng.) Baenkler, H. W.; Topf, G. (Institut und Poliklinik fur Klinische Immunologie der Universitat Erlangen-Nurnberg, D-8520 Erlangen, Krankenhausstr. 12, W. Germany). *Klin. Wochenschr.* 53(19): 927-928; 1975.

Serum and synovial-fluid of 27 patients with acute hepatitis were tested for the presence of hepatitis B antigen (HBAg). It was detected in the serum in 19 cases, in the synovial-fluid in 2 cases, but never in both serum and synovial-fluid. HBAg was not found in six patients. Polyarthritis was seen in 10 cases; 5 of them carried HBAg in the serum, and 2 carried it in the synovial-fluid. A hepatitis B, however, was also suspected in the three cases with polyarthritis lacking HBAg. The results suggest that virus B may also persist in joints and that polyarthritis associated with acute hepatitis is coupled to an infection with virus B.

2887 MEMBRANOUS GLOMERULONEPHRITIS ASSOCIATED WITH ACTIVE LIVER CIRRHOSIS BOTH INVOLVED BY HBs ANTIGEN. (Eng.) Moriyama, M.; Fukuda, Y.; Ishizaki, M.; Sugisaki, Y.; Masugi, Y. (Nippon Medical Sch., 1-1-5 Sendagi, Bunkyo-ku, Tokyo, Japan 113). *Acta Pathol. Jpn.* 26(2):237-250; 1976.

The case report of a 35-yr-old woman with a relatively short clinical course of severe liver cirrhosis and proteinuria is described. An autopsy revealed membranous glomerulonephritis associated with active liver cirrhosis. The liver demonstrated postnecrotic cirrhosis, having active hepatic signs with spotted acidophilic bodies in pseudolobuli with fatty change of hepatocytes, and prominent Kupffer cell mobilization in sinusoids. The kidneys showed typical membranous glomerulonephritis with diffuse thickening of glomerular basement membrane (GBM) and minimal cellular proliferation, having no distinct damage of vas afferens. Immunofluorescent study disclosed not only clustered hepatitis B surface antigen (HBsAg) in occasional hepatic cells, but also beaded granular type deposition of HBsAg, immunoglobulin (Ig) G, IgM, IgA, and complement C_3 along the renal GBM. Electron microscopy disclosed multiple particulate material in occasional bodies of hepatic cells and in subepithelial and subendothelial dense deposits along the GBM. The particles measured 200-400 A in diameter and were compatible with HBsAg. The majority of the particles were larger and were identified as Dane particles. Enzymatic immunoelectron microscopy confirmed that these particles, especially along the GBM, were HBsAg. It is concluded that the HBsAg-antibody complex is the pathogenetic factor that is responsible for the glomerular change of this particular case.

2888 HEPATITIS B SURFACE ANTIGEN AND ANTIBODY: A PROSPECTIVE STUDY IN ASYMPTOMATIC DRUG ABUSERS. (Eng.) Stimmel, B.; Vernace, S.; Schaffner, F. (Mt. Sinai Sch. Medicine, 100th St. and Fifth Ave., New York, NY 10029). *JAMA* 234(11):1135-1138; 1975.

The course of reactivity of hepatitis B surface antigen (HBsAg) and antibody (anti-HBs) in 238 asymptomatic heroin addicts entering methadone maintenance was followed up for periods of 1-4 yr. Sera were analyzed for HBsAg by solid-phase, double-antibody radioimmunoassay; anti-HBs was determined by passive hemagglutination. On initial determination, HBsAg was seen in 39.1%, anti-HBs in 10.5%, and HBsAg and anti-HBs in 9.2%; only 41.2% of persons tested had no detectable titers of either antigen or antibody. Abnormal liver function (i.e., SGOT levels >50 mIU, SGPT >50 mIU, alkaline phosphatase >85 mIU, and bilirubin >1.2 mg/100 ml) was found initially in 83%; there was no significant difference between those with or without HBsAg and anti-HBs. At the conclusion of each study year, 50-

60% of persons initially HBsAg-positive reverted to negative, and HBsAg was absent in all persons followed up through the fourth year of treatment. Anti-HBs persisted in two-thirds of the patients during the entire study. These results suggest that in addicts, the HBsAg carrier state is not maintained if exposure is eliminated.

LIVER AND BILIARY TRACT

Chronic Hepatitis

2899 CHRONIC HEPATITIS--A PERSPECTIVE ON CLASSIFICATION AND DETERMINANTS OF PROGNOSIS. (Eng.) Boyer, J. L. (Univ. Chicago, 950 E. 59th St., Box 400, IL 60637). *Gastroenterology* 70(6):1161-1171; 1976.

The etiology, histological type, prognosis based upon histology, and treatment of chronic persistent hepatitis (CPH) and chronic active hepatitis (CAP) are reviewed. Both CPH and CAH may follow infection with hepatitis B virus or they may be caused by drugs or unknown causes, including "autoimmunity." CPH, but no CAH, is also seen after infection with hepatitis A virus. The histological picture of liver biopsy material is usually characteristic and diagnostic for each type. In CPH, the overall architecture of the liver is normal. Portal triads are either normal or moderately enlarged and contain lymphocytic infiltration, and there may be mild hepatocyte necrosis. In CAH, there may or may not be evidence of cirrhosis. Three histologic types are identified in the absence of cirrhosis: periportal piecemeal necrosis and inflammation, which may or may not be precirrhotic; bridging hepatic necrosis, which is definitely precirrhotic; and a combination of periportal piecemeal necrosis with bridging hepatic necrosis, which is also definitely precirrhotic. CPH is nonagressive, and treatment consists of reassurance and periodic follow-up. For CAH with cirrhosis or precirrhotic histology, steroid treatment is indicated: prednisone, 40-60 mg/day for 1-2 weeks, tapering to 20 mg/day over 4-6 weeks, consistent with the control of symptoms and liver function without causing side effects; alternate drug therapy is then used when possible, or in combination with azathioprine. The role of steroid therapy in CAH with periportal piecemeal necrosis and inflammation is unclear.

2900 HEPATITIS B SURFACE ANTIGEN (HBsAg) IN THE LIVER OF PATIENTS WITH HEPATITIS: A COMPARISON WITH SEROLOGICAL DETECTION.

(Eng.) Ray, M. B.; Desmet, V. J.; Fevery, J.; De Groote, J.; Bradburne, A. F.; Desmyter, J. (Akademisch Ziekenhuis Sint Rafael, Univ. Leuven, B-3000 Leuven, Belgium). *J. Clin. Pathol.* 29(2):89-93; 1976.

The immunofluorescent detection of hepatitis B surface antigen (HBsAg) in the liver of biopsy-proven hepatitis was compared with results of radioimmunoassay in the serum. In addition, the HBsAg status was compared with the presence of various histological forms of hepatitis; in chronic hepatitis, an attempt was made to correlate the HBsAg status and the histological type of disease with sex, gammaglobulin, transaminase values, and the presence of auto-immune antibodies. Chronic hepatitis was diagnosed on liver biopsy of 76 patients; 52 had HBsAg. Of the 52 patients with HBsAg, 23% had HBsAg shown by immunofluorescence in the liver, while it could not be detected with radioimmunoassay in the serum; 77% had HBsAg detectable in liver and in serum, and none had HBsAg in serum only. HBsAg was detected more frequently in chronic aggressive hepatitis and active cirrhosis than in chronic persistent hepatitis and cirrhosis with little activity. No correlation was found in the different forms of chronic hepatitis between the HBsAg status and levels of transaminases, gammaglobulins, and auto-antibodies. Acute hepatitis was diagnosed on liver biopsy of 24 patients; 50% had HBsAg. Liver tissue positivity was very low in the fully developed stage compared to serum positivity. These findings are consistent with the hypothesis that HBsAg-positive cells are cleared at high efficiency in acute hepatitis by normal immunological mechanisms. In 146 patients with other liver ailments, both liver and serum were negative for HBsAg.

2901 DISTRIBUTION PATTERNS OF HEPATITIS B SURFACE ANTIGEN (HBsAg) IN THE LIVER OF HEPATITIS PATIENTS.

(Eng.) Ray, M. B.; Desmet, V. J.; Fevery, J.; De Groote, J.; Bradburne, A. F.; Desmyter, J. (Akademisch Ziekenhuis Sint Rafael, Univ. Leuven, B-3000 Leuven, Belgium). *J. Clin. Pathol.* 29(2):94-100; 1976.

One hundred liver biopsies from 100 hepatitis patients were examined for hepatitis B surface antigen (HBsAg) by the indirect immunofluorescent technique to determine different patterns of HBsAg localization and the role of this antigen in the different types of hepatitis. Of the 60 positive specimens, 52 were diagnosed as various types of chronic hepatitis, and 8 were acute hepatitis. Four main distribution patterns of HBsAg were obtained: full cytoplasmic fluorescence with diffuse lobular distribution, cytoplasmic fluorescence with spotty distribution, peripheral fluorescence in the cell membrane and/or cell peripheries, and focal cytoplasmic positivity. There was an inverse relation between the number of positive hepatocytes and the extent of liver cell necrosis. The distribution patterns of HBsAg were distinctive in each type of chronic hepatitis and in acute hepatitis. Homogeneous full cytoplasmic fluorescence, distributed diffusely in the whole liver lobule, was observed in chronic persistent hepatitis and in cirrhosis with little activity, whereas peripheral liver cell membrane and/or peripheral cytoplasmic fluorescence associated with cytoplasmic positivity in a smaller number of hepatocytes was a characteristic finding in chronic aggressive hepatitis, active cirrhosis, and acute hepatitis with possible transition to chronicity. Focal cytoplasmic fluorescence was observed in acute hepatitis and in a group of biopsies in chronic hepatitis in which HBsAg was detected in the liver but no antigen was detectable in the serum. The results indicate that the different patterns of HBsAg distribution in the liver biopsy are helpful for the histological diagnosis of different types of HBsAg-positive viral hepatitis and are consistent with the hypothesis of the role of specific immune response in the pathogenesis of type B viral hepatitis.

2902 LYMPHOCYTE CYTOTOXICITY TO ISOLATED HEPATOCYTES IN CHRONIC ACTIVE HEPATITIS. THE ROLE OF T- AND B-CELLS.

(Eng.) Eddleston, A. L. W. F. (Liver Unit, King's Coll. Hosp., London, S.E. 5, England). *Tijdschr. Gastroenterol.* 18(6): 359-366; 1975.

The lymphocyte cytotoxicity to isolated rabbit hepatocytes was investigated in 22 patients with chronic active hepatitis, and the role of T- and B-cells was determined. A microcytotoxicity assay of lymphocytes from 20 of the 22 patients showed a significant cytotoxic effect on the isolated hepatocytes, whereas this was only rarely observed in patients with other chronic liver diseases. The cytotoxicity was almost completely blocked by the addition of 0.5 μg human or rabbit liver specific lipoprotein but not by a similar material prepared from human kidney. This suggests that the cytotoxicity was due to an immunological reaction directed specifically at the hepatocyte surface lipoprotein and it implies that this same reaction may be the basis of the *in vivo* liver damage. T- and B-cell preparations were made from the peripheral blood of 14 patients with uncontrolled or untreated chronic active hepatitis and they were tested for their cytotoxic effect on isolated rabbit hepatocytes. In all cases, removal of T-cells enhanced the development of cytotoxicity. In contrast, when cells forming EAS rosettes were removed, leaving a lymphocyte population enriched in T-cells, the cytotoxic effect was considerably diminished; the results fell into the normal range, in all but one of the cases.

2903 ANTI-ACTIN SPECIFICITY OF HUMAN SMOOTH MUSCLE ANTIBODIES IN CHRONIC ACTIVE HEPATITIS. (Eng.) Lidman, K.; Biberfeld, G.; Fagraeus, A.; Norberg, R.; Torstensson, R.; Utter, G.; Carlsson, L.; Luca, J.; Lindberg, U. (Natl. Bacteriological Lab., 105 21 Stockholm, Sweden). *Clin. Exp. Immunol.* 24(2):266-272; 1976.

F-actin was isolated from rabbit skeletal muscle and the formation of F-actin-smooth muscle antibody (SMA) complexes in high titer, broad-reacting SMA-positive sera was investigated by indirect immunofluorescence. The SMA-positive sera (derived from 30 patients, all but 1 with chronic active hepatitis) had titers $\geq$ 100 when reacted with smooth muscle fibers of rat stomach, rat renal glomeruli, and with the membrane region of thyroid cells. The smooth muscle and other relevant cell staining were abolished after absorption of sera with actin, and were found to be homogeneous by sodium dodecyl sulfate gel-electrophoresis and by electron microscopy. The actin antibodies were purified by precipitation of sera with F-actin and elution of the precipitates at acid pH. The purified antibodies stained all tissues in the same way as the original sera. In double immunodiffusion tests, all 30 sera gave precipitation with actin. It is concluded that these broad-reacting smooth muscle antibodies are directed against actin. The finding of high-titered smooth muscle antibody is of diagnostic value and supports the clinical diagnosis of active chronic hepatitis. In addition, anti-actin antibodies eluted from human sera are a suitable tool for studying actin-containing cellular structures.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

2914 IRON DEPOSITS IN CHRONIC ALCOHOLICS. SPECIAL STUDIES IN RELATION TO THE IRON CONTAINED IN RED WINE. (Eng.) Miralles Garcia, J. M.; de Castro del Pozo, S. (Faculty Medicine, Univ. Salamanca, Spain). *Acta Hepatogastroenterol.* 23(1):10-19; 1976.

The iron deposits of 52 chronic alcoholics were analyzed to determine the possible relation between the quantity of iron ingested with the beverage and the level of this metal reserve in the body. All but three of the subjects were wine alcoholics. Three idiopathic hemochromatosis patients who did not consume alcohol were also studied. Using the desferrioxamine-B test, the mean value of iron in 24-hr urine was 1.33 mg for alcoholics, 1.10 mg for controls, and 2.50-28 mg for the patients with idiopathic hemochromatosis. Using the diethylenetriaminopenta-acetic acid test, the values of iron in the 6-hr urine for the same groups were 0.44 mg, 0.21 mg, and 0.52-8.21 mg, resp. In determining the iron concentration in the liver, part of the hepatic cylinder was preserved in a 5% formalin solution and another part of the same cylinder was kept in an absolute alcohol solution. Using the formalin solution, the amount of hepatic iron was 171.65 mg/100 g for the alcoholics and 84.76 mg/100 g for controls. Using the absolute alcohol determination, the corresponding values were 249.96 mg/100 g and 115 mg/100 g. There was no statistically significant relation between the quantity of iron ingested with the alcoholic beverage and the values obtained by the different methods for determining the reserve iron. Thus, the quantity of iron deposits in these alcoholics was independent of the quantity of metal ingested with the alcoholic beverage. These results do not support the theory that hemochromatosis is idiopathic. The three cases of primitive hemochromatosis tend to support the theory of the genetic origin of idiopathic hemochromatosis.

2915 TEST FOR ALCOHOLIC CIRRHOSIS BY CONVERSION OF [^{14}C]- OR [^{13}C]GALACTOSE TO EXPIRED CO_2. (Eng.) Shreeve, W. W.; Shoop, J. D.; Ott, D. G.; McInteer, B. B. (Veterans Admin. Hosp., Northport, NY 11768). *Gastroenterology* 71(1):98-101; 1976.

The rate of oxidation of an ingested C-labeled galactose load to expired carbon dioxide was measured to determine whether it could provide diagnostic information analogous to that of galactose clearance from the blood. Breath was collected from subjects at intervals for 4 hr, following ingestion of galactose (10 g/m^2) labeled with ^{14}C or ^{13}C. $^{14}CO_2$ was then measured by liquid scintillation counting, and $^{13}CO_2$ was measured by mass spectrometry. Nine subjects without liver disease and 21 cirrhotic patients were tested with ^{14}C. Eight control subjects and four patients with diagnosis of cirrhosis were tested with ^{13}C. The mean rates of expiration of labeled CO_2 by the patients with cirrhosis were one-third to one-half of mean normal rates during the first 90 min. The time of peak concentration of tracer CO_2 for cirrhotic patients (150-180 min) was later than for normal subjects (90-120 min). There was distinctly greater separation between control and liver disease groups by test of $^{14}CO_2$ radioactivity at 1 hr than by serum alkaline phosphatase, total bilirubin, and transaminase, but only slightly better separation than by serum albumin concentration (which was highly correlated with $^{14}CO_2$ output). It is concluded that the [^{14}C]galactose test is simpler than the standard i.v. galactose tolerance test and, like the latter, appears superior to some other tests for recognition of cirrhosis. The use of ^{13}C provides an example of a new direction for clinical application of this stable, nonradioactive nuclide.

2916 ALCOHOLIC HEPATITIS: CELL-MEDIATED IMMUNOLOGICAL RESPONSE TO ALCOHOLIC HYALIN. (Eng.) Zetterman, R. K.; Luisada-Opper, A.; Leevy, C. M. (New Jersey Medical Sch., Room 1501, 100 Bergen St., Newark, NJ 07103). *Gastroenterology* 70(3):382-384; 1976.

A purified isolate of alcoholic hyalin was added to lymphocytes from healthy subjects and patients with alcoholic hepatitis or other hepatic disorders (acute viral hepatitis, fatty liver, and inactive cirrhosis) to determine its relation to lymphocyte hyperreactivity to homologous liver. Production of migration inhibition factor (MIF) in response to this material was used as an index to lymphocyte reactivity. MIF was significantly increased in lymphocytes obtained from patients with alcoholic hepatitis, as compared to the healthy controls ($p<0.001$) and persons with other liver disease ($p<0.05$). These observations indicate that immunological hyperreactivity to alcoholic hyalin occurs in patients with alcoholic hepatitis. Such activity may be of key importance in the pathogenesis or sequelae (or both) of this disease.

Cirrhosis

2921 ACID-BASE STATUS IN LIVER CIRRHOSIS: DISTURBANCES IN STABLE, TERMINAL AND PORTACAVAL SHUNTED PATIENTS. (Eng.) Prytz, H.; Thomsen, A. C. (Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen N.V., Denmark). *Scand. J. Gastroenterol.* 11(3):249-256; 1976.

Acid-base status was determined in 86 patients with liver cirrhosis. Group 1 comprised 55 patients living over 3 months after examination (stable). Group 2 was composed of another 18 stable patients with a surgical portacaval shunt (p.c.a.). Group 3 consisted of 12 terminal patients without p.c.a. who were examined within the last week of life. With respect to liver function, group 2 was intermediate between 1 and 3. The most common acid-base disturbance in group 1 was compensated respiratory alkalosis (14 patients) followed by compensated metabolic alkalosis (9 patients). Nine patients in group 2 preented with compensated respiratory alkalosis. Eleven patients in group 3 showed metabolic acidosis, which was compensated in only half of the patients. Respiratory alkalosis seemed more related to impairment of liver function than to portasystemic shunting. The genesis of the terminal metabolic acidosis was complex. Renal function was reduced in 11 patients in group 3, and lactic acidosis was found in 4 patients. In this group, hepatic function was most severely impaired, and seven patients were hypotensive. These disturbances were not related to etiology or treatment of the liver disease. It is concluded that acid-base determinations be used in patients with deteriorating cirrhosis, because of their prognostic value.

2922 SERUM BILE ACIDS IN PRIMARY BILIARY CIRRHOSIS. (Eng.) Bloomer, J. R.; Allen, R. M.; Klatskin, G. (333 Cedar St., New Haven, CT 06510). *Arch. Intern. Med.* 136(1):57-61; 1976.

The use of serum bile acid levels to determine the severity and progression of primary biliary cirrhosis was studied. Fasting serum bile acid levels were measured by gas-liquid chromatography in 56 patients. Of these, 52 had increased levels (>2 μg/ml), including 14 of the 18 with normal serum bilirubin concentrations. The four patients with normal bile acid levels had early lesions, as judged by liver biopsy (minimal portal fibrosis and normal lobular architecture), and the lack of jaundice and pruritus. With progression of the disease, total bile acid levels increased, and the ratio of serum cholic-to-chenodeoxycholic acid decreased. Ratios of serum cholic-to-chenodeoxycholic acid below 1 occurred predominantly in patients with advanced or terminal disease. These studies suggest that serial measurement of serum bile acids may aid in the evaluation of primary biliary cirrhosis and that it is another objective factor with which to evaluate the effects of therapy.

2923 PLASMA ANGIOTENSIN ACTIVITY IN CIRRHOSIS OF THE LIVER AND IDIOPATHIC PORTAL HYPERTENSION. (Eng.) Dass, B. K.; Chaudhury, R. R.; Chhuttani, P. N.; Saini, V. K.; Datta, D. V. (Postgraduate Inst. Medical Education and Res., Chandigarh, India). *Indian J. Med. Res.* 64(3):418-424; 1976.

Plasma angiotensin activity was measured in 12 controls, in 30 patients with cirrhosis, in 10 patients with idiopathic portal hypertension, in 6 patients with extrahepatic portal vein obstruction, and in 5 patients with acute viral hepatitis. Plasma angiotensin activity was significantly elevated above levels in all of these clinical conditions ($p<0.001$). There was no significant correlation between liver function tests and plasma angiotensin activity. Patients with ascites had higher plasma angiotensin activity than patients without ascites (50.8 ± 16.02 ng/ml compared with 40.2 ± 5.18). Plasma clearance of infused angiotensin was delayed in cirrhosis and idiopathic portal hypertension. Infusion of angiotensin in peripheral and portal veins, separately in cirrhosis and idiopathic portal hypertension, revealed similar changes in systemic blood pressure and plasma angiotensin levels. However, in control subjects, the systemic blood pressure rose significantly when angiotension was infused in the peripheral vein; the response with portal infusion was not remarkable. It is concluded that reduced inactivation of plasma angiotensin is one of the causes of its high levels in acute and chronic liver disease.

2924 ALPHA 1-ANTITRYPSIN PHENOTYPES IN CIRRHOSIS AND HEPATOMA. (Eng.) Theodoropoulos, G.; Fertakis, A.; Archimandritis, A.; Kapordelis, C.; Angelopoulos, B. (Sch. Medicine, Univ. Athens, Athens-609, Greece). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):114-117; 1976.

The relation between the protease inhibitor (Pi) system and the development of cirrhosis or hepatoma was investigated by determining the phenotypic distribution of α1-antitrypsin variants in 101 patients with cirrhosis, in 50 patients with both cirrhosis and hepatoma, and in 504 healthy controls. The ZZ and MZ phenotypes were found only once in the group of patients with cirrhosis. The very low Pi^z gene frequency suggests that the association of Pi^z gene with cirrhosis is fortuitous. The FM phenotype was observed in 14% of patients with hepatoma plus cirrhosis, and this incidence differed significantly between the two groups of patients and the controls. It is suggested that phenotypically FM cirrhotic patients are prone to the development of hepatoma.

2925 ALPHA-1 ANTITRYPSIN AND INDIAN CHILDHOOD CIRRHOSIS. (Eng.) Reddy, V.; Raghuramulu, N. (Indian Council Medical Res., Jamai-Osmania, Hyderabad-500007, India). *Indian J. Med. Res.* 63(9):1286-1288; 1975.

Serum α-1 antitrypsin activity was studied using benzoyl-d-arginine-*p*-nitro anilide as substrate in 10 normal children, in 20 children with Indian childhood cirrhosis, and in 3 subjects with other liver diseases. The antitrypsin activity in children with liver disease was similar to that of normal subjects (0.46-0.72 mg/ml), indicating that the deficiency of this protein is not related to Indian childhood cirrhosis. Genetic predisposition seems to be important in the development of this disease.

2926 EFFECTS OF PHOTOTHERAPY ON HEPATIC FUNCTION IN HUMAN ALCOHOLIC CIRRHOSIS. (Eng.) Knodell, R. G.; Cheney, H.; Ostrow, J. D. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *Gastroenterology* 70(6):1112-1116; 1976.

The effects of phototherapy on bile acid kinetics, bile composition, serum liver function tests, and bromosulfophthalein (BSP) kinetics were examined in eight jaundiced patients with biopsy-documented alcoholic cirrhosis. Phototherapy was provided by four high intensity fluorescent bulbs that delivered 1000 foot candles of illumination at the body surface. Correlation coefficients for specific activity decay curves for cholic and chenodeoxycholic acid (CDC), during control and phototherapy periods, ranged from 0.01 to 0.99, and all regression lines were statistically significant at the $p<0.05$ level or less. There was a statistically significant increase in slope during phototherapy, for both bile acids ($p<0.01$, cholic and $p<0.05$), CDC). Biliary phospholipid concentrations increased ($p<0.02$), but no increase in cholesterol concentrations ($p<0.20$) was observed. Thin layer chromatography of both control and phototherapy bile samples revealed that over 98% of the bilirubin was conjugated. No significant changes in serum alkaline phosphatase, SGOT, albumin, or total protein occurred from the control period to the end of the study. It is concluded that phototherapy causes little improvement in intrinsic liver function, but it does produce specific changes in bile acid metabolism; these changes may be related to effects of light on a cutaneous bile acid pool.

2927 COMPARATIVE STUDIES OF THE ELECTROENCEPHALOGRAM AND THE CEREBRAL OXIDATIVE METABOLISM IN PATIENTS WITH LIVER CIRRHOSIS. (Eng.) Papenberg, J.; Lanzinger, G.; Kommerell, B.; Hoyer, S. (Medizinische Universitats-Klinik, D-6900 Heidelberg, Bergheimer Strasse 58, Heidelberg, W. Germany). *Klin. Worchenschr.* 53(23):1107-1113; 1975.

Comparative studies of the EEG and the cerebral oxidative metabolism were conducted in 24 fasting patients with liver cirrhosis to determine the extent to which disorders of cerebral oxidative metabolism occur. The patients were divided in two groups. The EEG in all patients of group A (8) was normal, while the patients of group B showed EEG changes of severity grade 3 (4), severity grade 4 (3), and severity grade 5 (1). The serum parameters for all patients were characteristic for hepatic insufficiency. Compared to group A, the serum albumin in group B (2.9 g/100 ml) was significantly lowered, and the total bilirubin (2.4 mg/100 ml) was significantly raised. The regularly raised ammonia levels in groups A and B (262 and 259 μg/ml, resp.,) were noteworthy. The prothrombin time (Quick value) was lowered, the alkaline phosphatase and SGOT were raised slightly, and the urea values were normal in both groups. The values for blood sugar, oxygen, carbon dioxide, and pH were normal in all patients of groups A and B. Cerebral oxygen consumption in the patients of Group B (2.5 ml/100 g/min was significantly lower than in group A. The lactate/glucose index (quotient) was raised in group A (0.03) and group B (0.17). The arterio-venous difference for ammonia was about 3.5 times higher in the patients of both groups. It is suggested that glucose and ammonia metabolism can be disturbed without simultaneous changes in the EEG (group A). The results from group B patients indicate that marked changes in EEG result only if cerebral oxygen consumption is reduced as well.

2928 EXOCRINE PANCREATIC FUNCTION IN HEPATIC CIRRHOSIS. (Eng.) Lee, S. P.; Lai, K. S. (Auckland Hosp., Auckland, New Zealand). *Am. J. Gastroenterol.* 65(3):244-248; 1976.

Exocrine pancreatic function was assessed in 13 patients with postnecrotic cirrhosis of the liver, 6 of whom had a splenorenal anastomosis for repeated variceal bleeding, and in 10 healthy controls. Pancreatic function was assessed by the standard test meal (TM) stimulation in all patients. The shunt patients had pancreatic function reassessed 3 months after operation by this test; three of these patients also had pancreatic function assessed by the secretin-pancreozymin (SP) stimulation test (using 2 clinical U/kg and 1.5 clinical U/kg, resp.) pre-operatively and 3 months after operation. There was no significant difference in mean trypsin concentration between the unoperated cirrhotic group and the controls; however, the volume of secretion was significantly higher in the former. The patients with splenorenal shunts showed a significant increase in the total volume recovered during the stimulation test ($p<0.001$) and in mean trypsin concentration ($p<0.05$). There was no appreciable difference in the volume and enzyme secretion when four unoperated patients with cirrhosis were reassessed after 4-14 months, and there was no difference in volume or output using either the TM or the SP test. It is concluded that there is no functional pancreatic impairment in postnecrotic cirrhosis as tested by these methods. The increases in volume and enzyme output after splenorenal shunt are probably due to a bypass of the liver with resultant impairment of hepatic degradation of pancreatic secretagogues.

2929 MANAGEMENT OF BLEEDING VARICES IN CIRRHOSIS: A CRITICAL EXAMINATION. (Eng.) Resnick, R. H. (Lemuel Shattuck Hosp., Boston, MA 02130). *Scand. J. Gastroenterol.* 10(7):673-678; 1975.

Traditional and new procedures for the management of bleeding varices in cirrhosis are examined. The choice of procedure (such as splenic venography, transhepatic venography, superior mesenteric angiography, or portal venography via the umbilical vein) depends upon specific patient needs and the expertise of attending clinicians. For the persistent bleeder, two modalities of non-operative treatment are available: a modification of the Sengstaken-Blakemore tube and selective intra-arterial vasopressin (VP) infusion. The end-side portacaval anastomosis (PCA) was introduced by Whipple in 1945. Results from controlled studies of prophylactic and therapeutic PCA, as well as experiences with portasystemic shunt in schistosomal (non-cirrhotic) hepatic disease led to the hypothesis that acute diversion of portal venous blood from the liver jeopardizes the functional integrity of that organ. A number of new procedures, designed to conserve total hepatic blood flow by varying methods include: the central side to side splenorenal shunt; an end to side distal splenorenal shunt coupled with isolation of the gastroesophageal venous circulation by ligating the coronary, right gastric, and right gastroepiploic veins; hepatic arterialization of the portal vein coupled with a standard end side portacaval shunt; and the mesocaval shunt employing a dacron H-graft prosthesis. Advocacy or rejection of these newer techniques can only be determined through prospective controlled trials.

2930 L-DOPA IN HEPATIC COMA. (Eng.) Fischer, J. E.; Funovics, J. M.; Falcao, H. A.; Wesdorp, R. I. C. (Massachusetts General Hosp., Boston, MA 02114). *Ann. Surg.* 183(4):386-391; 1976.

Experience with a heterogenous group of patients in hepatic coma, treated over the past 4 yr with L-Dopa, is presented. Thirty-five patients (mean age, 53 yr) with severe liver disease, including nutritional cirrhosis with acute coma and acute hepatitis, were treated. Four patients were judged grade III, and 31 patients were judged grade IV. All patients were previously treated with protein restriction, p.o.-administered nonabsorbable antibiotics, fluid and electrolytes, and in some cases, steroids. L-Dopa was given p.o. (500 mg at 4 hourly intervals) in 21 patients, and as a retention enema (500 mg at 6 hourly intervals) in 14. Thirteen of the 35 patients did not respond to therapy. Seventeen responded, but did not survive, and five patients responded and survived. There was no difference between any of the groups as far as dosage of L-Dopa and clinical features. In the survivors, therapy was started within 1.4 days after the onset of coma. In the patients who responded but did not survive, therapy was initiated at 6.7 days, and in the nonresponders, 9.5 days. These differences are highly significant. The results suggest that coma may pass from a reversible to an irreversible stage, and that initiation of L-Dopa therapy during the early stages of hepatic coma may be beneficial.

2931 INTERPOSITION GRAFTING FOR PORTAL HYPERTENSION. (Eng.) Thompson, B. W.; Read, R. C.; Casali, R. E. (Veterans Admin. Hosp., 300 E. Roosevelt Rd., Little Rock, AR 72206). *Am. J. Surg.* 130(6):733-738; 1975.

Experience with 37 patients who underwent interposition graft shunting during a 6-yr period is presented. The operation was performed in 33 cases for bleeding from varices and in 5 cases for intractable ascites. The procedure was elective in 27 cases and it was performed in an emergency in 11 cases. Autogenous jugular vein was used in 25 instances, homologous vena cava in 9, and Dacron in 4. Portacaval anastomoses were performed in 19 instances and mesocaval anastomoses in 19. There were five early deaths with one in the elective and four in the emergency group. Twelve grafts were open at autopsy, 15 at splenoportography, and 7 were assumed to be patent because the patients were asymptomatic. Two Dacron grafts and two homografts thrombosed. There were 10 late deaths, and only 1 was related to graft failure. Apparently, the operation controls ascites. Autogenous jugular vein appears to be the ideal material. It is concluded that interposition grafting is a simple, safe procedure that can be used for portal decompression in patients with bleeding varices.

2932 TRANSPOSITION OF THE SPLEEN IN RATS WITH PORTAL HYPERTENSION. (Eng.) Bengmark, S.; Borjesson, B.; Olin, T. (Dept. Surgery, Univ. Lund, Lund, Sweden). *Br. J. Surg.* 63(4):268-271; 1976.

The effect of subcutaneous transposition of the spleen on collateral circulation and portal pressure was studied in Sprague-Dawley rats with induced portal hypertension. Portal hypertension was induced in 36 animals by ameroid constrictors and in 30 animals by intragastric administration of 2.5 ml of a solution of dimethylnitrosamine (DMNA; 500 ppm) once a day for 3 consecutive days over 6 weeks. In the former group, subcutaneous transposition of the spleen was performed when the constrictor was applied, and for the latter group, it was performed 1 week before DMNA administration. In the constrictor group, parasplenic collaterals did not develop in animals, which were not subjected to subcutaneous transposition; however, in rats, which were subjected to the procedure, most of the collaterals were parasplenic, and the portal venous pressure fell. In the animals with DMNA-induced cirrhosis, most portasystemic collaterals were over the left renal vein in animals without transposition; in those with transposition, there were wide splenic collaterals. Collateral circulation in relation to the esophagus was absent in all animals.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

2943 NEWER ANGIOGRAPHIC OBSERVATIONS IN CHOLANGIOCARCINOMA. (Eng.) Walter, J. F.; Bookstein, J. J.; Bouffard, E. V. (Palo Alto Medical Clinic, Palo Alto, CA). *Radiology* 118(1):19-23; 1976.

Three new angiographic features (bile duct dilatation, venous obstruction, and arterio-arterial collaterals) in the diagnosis and pre-operative evaluation of cholangiocarcinoma are described. These were noted in a review of angiograms from 15 cases of primary adenocarcinomas of the biliary tract. Dilatation of intrahepatic bile ducts was recognized in 67% of the cases and was usually best seen in the hepatoportagram phase of a high dose superior mesenteric artery injection augmented by tolazoline. Focal encasement of the portal vein was seen in 27% of the cases, and the obstruction was more proximal than that usually caused by pancreatic carcinoma. Arterio-arterial collaterals were seen in a single case. This patient was examined angiographically 4 times within 3 months. But in the fourth examination, a piece of partially necrotic tumor was obtained, enabling correct diagnosis. A confident prospective angiographic diagnosis of cholangiocarcinoma was made in 11 of the 15 patients. Because of its high reliability and the difficulties of operative diagnosis, angiography can play an important diagnostic role in patients with suspected cholangiocarcinoma.

2944 SEPSIS COMPLICATIONS IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) James, E. C.; Collin, D. B. (West Virginia Univ. Medical Center, Morgantown, WV 26506). *Am. Surg.* 42(4):229-232; 1976.

Experiences with 71 endoscopic retrograde cholangiopancreatographic examinations in a group of 63 patients are presented. Successful cannulation was managed in 56 of the 63 patients and in 59 of the 71 examinations. Successful duct cholangiograms were obtained in 16 of 18 procedures in 15 patients with jaundice and in 10 of 13 procedures in 13 patients who were believed to manifest anicteric biliary tract disease. Successful duct pancreatograms were obtained in 23 of 25 procedures performed in 20 patients with proven chronic pancreatitis, in 8 of 13 procedures in 13 patients with suspected occult pancreatitis, and in both procedures performed in 2 patients with pancreatic trauma. Thus, success significantly outweighed failure in all patient categories except in the group with occult pancreatitis. Pseudocysts occurred in six cases of proven chronic pancreatitis; abscesses developed after cannulation in two patients. Both patients developed high fever, generalized toxicity, and gram-negative bacteremia and required immediate surgical drainage. Both patients survived, but not without a great deal of morbidity and extended hospitalization. Although this represented only a 2.8% overall incidence of infection, it constituted a 33.3% rate in the 6 patients with pseudocysts. It is recommended that routine endoscopic retrograde cholangiopancreatography be contraindicated in patients with suspected pseudocysts.

2945 DIAGNOSTIC ACCURACY OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN HEPATIC, BILIARY, AND PANCREATIC MALIGNANCY.

(Eng.) Silvis, S. E.; Rohrmann, C. A.; Vennes, J. A. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Ann. Intern. Med.* 84(4):438-440; 1976.

The accuracy of endoscopic retrograde cholangiopancreatography was evaluated in 84 patients with biopsy-proven pancreatic and biliary malignancy, and the diagnostic features of malignancy shared by both organ systems were clarified. In the 73 successful radiologic studies, a diagnosis of tumor was made in 67 patients (92%). The study was successful in 40 of 43 patients with pancreatic carcinoma and diagnosis was made in 37 on the basis of stenosis or obstruction of the ducts. There were 33 successful studies in the 41 patients with miscellaneous tumors, including primary bile duct, ampullary, gallbladder, metastatic carcinoma, lymphoma, and hepatoma. A diagnosis of tumor was made in 30 studies. The hallmark of malignancy in the pancreatic and biliary tract was determined to be obstruction and stenosis. This study indicates that malignant disease of the pancreas and biliary tract is accurately assessed by this endoscopic method.

2946 THE VALUE OF COMBINATION OF ANTEGRADE AND RETROGRADE CHOLANGIOGRAPHY IN THE DIAGNOSIS OF BILE DUCT OBSTRUCTION.

(Eng.) Huchzermeyer, H.; Luska, G.; Otto, P.; Seifert, E. (Medizinischen Hochschule, 3 Hannover, Karl-Wiechert-Allee 9, W. Germany). *Endoscopy* 7(3):126-133; 1975.

The advantages of combined antegrade (percutaneous transjugular cholangiography, PTC) and retrograde (endoscopic retrograde cholangiopancreatography, ERCP) cholangiography in the diagnosis of bile duct obstruction are illustrated in three cases. The limits of an adenocarcinoma were determined preoperatively in a 54-yr-old woman, using the combined technique. In a 60-yr-old man, ERCP, by choledocho-duodenostomy showed obstruction of the common bile duct 2 cm above the anastomotic stoma; this was thought to be carcinoma of the pancreas. PTC indicated that the upper part of the common bile duct was not visible and ruled out the possibility of anastomosis with an hepatic duct. In a 61-yr-old man with posthepatic cirrhosis, ERCP indicated an abruption of the common duct up to the cystic duct with an irregular contour, suggesting tumor compression. PTC revealed a narrowed upper choledochus duct, which appeared destroyed by tumor formation at the liver hilus. Surgery revealed a papillary adenocarcinoma originating from the bile duct. ERCP, PTC, peritoneoscopic, or percutaneous transhepatic cholangiography are the most suitable methods to determine the type and cause of bile duct obstruction preoperatively, in cases of severe jaundice. ERCP is considered to be most satisfactory in approximately 80% of the cases, but when the entire duct system cannot be visualized by this method, PTC may offer valuable information.

2947 TRANSJUGULAR APPROACH TO THE LIVER, BILIARY SYSTEM, AND PORTAL CIRCULATION.

(Eng.) Rosch, J.; Antonovic, R.; Dotter, C. T. (Univ. Oregon Health Sciences Center, 3181 S.W. Sam Jackson Park Rd., Portland, OR 97201). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(3):602-608; 1975.

Over 5 yr of clinical and animal experience with the use of a transjugular approach to the liver, biliary system, and portal circulation is reviewed. A catheter was inserted into an internal jugular vein (3-4 cm below the angle of the mandible) in humans and into the external jugular vein in animals. The procedure has been of clinical value in connection with hepatic manometry and venography, liver biopsy, and cholangiography. Satisfactory hepatic manometry and venography were achieved by the transjugular approach in all 47 attempted cases. Diagnostic liver specimens were obtained in 71 of 83 patients, and cholangiography was successful in 48 of 52 patients with enlarged intrahepatic ducts. No complications occurred with these studies. In animals, transjugular catheterization was used as a means for portal, mesenteric, and pancreatic venography. These procedures are ready for diagnostic clinical use. Therapeutic techniques explored in animals include intravascular tamponade of gastric coronary vein and the nonsurgical creation of intrahepatic portacaval shunts. It is suggested that both procedures show promise in the future management of massive gastrointestinal bleeding from varices.

2948 URSODEOXYCHOLATE--A COMMON BILE ACID IN GALLBLADDER BILE OF JAPANESE SUBJECTS.

(Eng.) Igimi, H. (Kyushu Univ., Fukuoka, 812, Japan). *Life Sci.* 18(9):933-1000; 1976.

Bile acid composition was investigated in normal gallbladder bile collected from 10 Japanese patients suffering from diseases other than those involving the hepatobiliary tract to determine the presence of ursodeoxycholate (UDCA). Bile samples were collected by aspirating from the gallbladder with a syringe at laparotomy. Standard commercial solutions of bile acids and free bile acids extracted from the bile of patients were derived to their methyl ester-trimethylsilyl ethers. They were determined by gas liquid chromatography on a column of 3% poly-phenyldiethanol amine succinate-80-100 mesh Chromosorb WHP. Average recoveries of added amount of standard bile acids ranged from 97-100%. UDCA was detected as a predominant bile acid in all cases tested and it represented an average of 5.7% of the total bile acids. In all but one case, its quantity was higher than that of lithocholate. The average percentage of the total bile acids for the other major acids was 40.3% for cholate, 17.0% for deoxycholate, and 35.5% for chenodeoxycholate. A higher content of UDCA than of lithocholate may indicate a reversible metabolic pathway where 7-ketolithocholate acts as an intermediate, and this pathway may be one of the protective processes in the body.

2949 HEPATIC PORTO-ENTEROSTOMY OR CHOLECYSTOSTOMY IN THE TREATMENT OF EXTRAHEPATIC BILIARY ATRESIA: A STUDY OF 49 CASES.

(Eng.) Odievre, M.; Valayer, J.; Razemon-Pinta, M.; Habib, E. C.; Alagille, D. (Hopital d'Enfants, 78 rue du General-Leclerc, 94270 Kremlin-Bicetre, France). *J. Pediatr.* 88(5):774-779; 1976.

The use of hepatic porto-enterostomy or hepatic porto-cholecystostomy was evaluated in the treatment of 49 infants with biliary atresia. Five infants died during the first 2 postoperative weeks; sepsis was the cause of death in four and unexplained gastrointestinal bleeding was the cause in one. Of the 44 patients who survived this period, cholestasis was not improved in 13 and bile flow was restored in 31. Of the 31 infants who excreted bile at the operation, 20 experienced repeated attacks of cholangitis with prolonged periods of fever and acholic stools. Death was directly related to cholangitis in three patients. Biliary leak with bile peritonitis occurred in six patients; four were treated with hepatic porto-cholecystostomy. Portal hypertension developed in 13/23 survivors 1 or more years after surgery. Twenty-one survivors of the postoperative period died during the subsequent 5-yr period. The mortality rate was 50% in infants who had surgery at less than 3 months of age and 59% in infants who had surgery at later ages. Of the 23 survivors, 8 are 3 yr of age or older; 6 are anicteric and free from pruritus, and 2 have chronic cholangitis. All eight have an enlarged, firm liver with extensive periportal scarring. Portal hypertension was confirmed in seven of the eight. Of the 15 surviving infants who are less than 3 yr of age, 7 suffer from chronic or recurrent cholangitis, 1 survived postoperative bile leakage with bile peritonitis, 5 have portal hypertension, and 7 have unrelieved cholestasis. One infant, 21 months of age, is free of abnormal findings. These results indicate significant improvement over earlier series. The findings also support the view that nearly all infants with biliary atresia who survive the first postoperative month develop chronic liver disease even when bile flow is restored.

2950 A VIEW ON THE AETIOLOGY OF EXTRAHEPATIC BILIARY ATRESIA WITH COMMENTS ON SURGICAL TREATMENT.

(Eng.) Puri, P.; Carroll, R.; O'Donnell, J.; Guiney, E. J. (Our Lady's Hosp. Sick Children, Dublin 12, Ireland). *Z. Kinderchir. Grenzgeb.* 17(1):44-55; 1975.

Clinical findings and treatment results of a series of 22 infants with biliary atresia are discussed. The site of atresia was diagnosed at laparotomy or autopsy. Jaundice was present at birth in 5 infants, it developed in less than a week in 11, and it developed in less than 4-5 weeks in 6 cases. Liver chemistries included: bilirubin, 3.5-25 mg/100 ml; conjugated bilirubin, 2.7-14.9 mg/100 ml; SGOT, 42-1,050 U; SGPT, 42-730 U; and alkaline phosphatase, 14-104 King Armstrong U. The anatomical abnormality involved atresia of the gallbladder and ducts in 13 cases, atresia of the common duct in 4, atresia of the hepatic duct in 1, and absence of the gallbladder and atresia of all ducts in 4. Surgery was performed at 1-6 months, and 4 of 22 patients had correctable lesions. Two of four were regarded as inoperable at laparotomy and the other two had choledochojejunostomy with Roux-en-y; one of these infants died and the other was alive at 14 months with abnormal liver chemistries and recurrent cholangitis. Of the 18 infants with incorrectable lesions, 8 had hepatic portoenterostomy with Roux-en-y and 5 had hepatic portojejunostomy. There were only five cases in which postoperative macroscopic evidence of bile excretion was observed. Eleven of 13 patients died within 22 months of surgery, and the other 2 were alive with evidence of progressive liver damage at 3 and 7 months postoperatively. It is concluded that hepatic portoenterostomy is probably a worthless procedure in the treatment of patients with incorrectable type extrahepatic biliary atresia. Pathological findings in this series included bile duct proliferation (18), bile duct retention (12), bile canaliculi retention (19), inflammation (19), fibrosis (18), thickening of hepatic arterial walls (7), cirrhosis (8), and liver cell damage (8).

2951 THE CONTINUING CHALLENGE OF GALLBLADDER CANCER: SURVEY OF THIRTY YEARS' EXPERIENCE AT THE UNIVERSITY OF CHICAGO.

(Eng.) Moossa, A. R.; Anagnost, M.; Hall, A. W.; Moraldi, A.; Skinner, D. B. (Univ. Chicago Hosp., 950 East 59th St., Chicago, IL 60637). *Am. J. Surg.* 130:57-62; 1975.

The records of 82 consecutive cases of gallbladder carcinoma in 21 men and 61 women are reviewed. Sixty-one of 82 patients had concomitant gallstones. Forty received no treatment, and of those treated, 28 had only surgery, 2 had surgery and irradiation, 5 received chemotherapy, and 4 had combined radiotherapy and chemotherapy. In the overall series, 42 died within 3 months of diagnosis, 57 died within 6 months, and 72 died within 1 yr. The overall 5-yr survival was 5% (4 patients). Of the 42 patients who were treated, 14 died within the first 3 months, but 19 were alive at 6 months, and 10 were alive at 1 yr; the 5-yr survival in this group was 9.5% (4 patients). In patients who were treated by only surgery, 22 of 28 survived the operation and the first 3 postoperative months, 14 were alive at 6 months, and 8 were alive at 1 yr; the 5-yr survival (same 4 patients) was 14.3%. Three men and seven women survived for more than 1 yr following the initial diagnosis. All ten had a preoperative history suggestive of cholelithiasis and cholecystitis of 6 months to 20 yr duration. Carcinoma was suspected at laparotomy in only four patients, and they all died at 14 months to 39 months post-diagnosis. Diagnosis was made on pathologic study in the six remaining patients. Among them, one died from metastatic gallbladder carcinoma at 22 months. Of the other five patients, one died at 22.5 yr from unrelated causes and another died at 6 yr from carcinoma of the floor of the mouth with no evidence of gallbladder carcinoma at the time of death. The remaining three were alive without evidence of disease at 12.5 yr, 6 yr, and 2 yr, resp. Of those receiving surgery and radiotherapy, one had obvious carcinoma at the time of the procedure and residual disease at 2.5 yr. Diagnosis was made by pathologic examination in the other. Histologically, anaplastic carcinoma extended to subserosal fat with lymphatic and perineural invasion. The only long term survivors were those in whom carcinoma was an incidental finding at surgery. It is concluded that there is adequate justification for cholecystectomy for reasons other than cancer when gallstones are discovered, especially when patients are above 50 yr of age.

2952 CARCINOMA OF THE AMPULLA OF VATER: REVIEW OF 38 CASES WITH EMPHASIS ON TREATMENT AND PROGNOSTIC FACTORS. (Eng.) Makipour, H.; Cooperman, A.; Danzi, J. T.; Farmer, R. G. (Cleveland Clinic Foundation, Cleveland, OH). *Ann. Surg.* 183(4):341-344; 1976.

Clinical information, laboratory data, and types and results of treatment in 38 cases of carcinoma of the ampulla of Vater are presented. The most common symptom was jaundice, and the diagnosis was confirmed at laparotomy in all patients. Three types of operation were performed: a pancreaticoduodenal resection in 23 patients, a biliary-enteric bypass in 7 patients, and a biliary-enteric bypass plus excision of tumor in 8 patients. The operative mortality was 8% following resection, 14% following bypass plus excision of the ampulla, and 13% following biliary-enteric bypass. Five patients survived for 5 yr or more. The two longest surviving patients had undergone pancreaticoduodenal resections (both were still alive at 216 months). The level of bilirubin or presence of pain did not correlate with prognosis. Prognosis was better in the absence of nodal metastases and in the presence of papillary tumors. The importance of screening and selecting candidates for the pancreaticoduodenal resection is stressed, because the 5-yr survival in the presence of regional or lymph node metastases is limited.

2953 ADENOCARCINOMA IN BILIARY PAPILLOMATOSIS. (Eng.) Neumann, R. D.; LiVolsi, V. A.; Rosenthal, N. S.; Burrell, M.; Ball, T. J. (Yale Univ. Sch. Medicine, 310 Cedar St., New Haven, CT 06510). *Gastroenterology* 70(5):779-782; 1976.

The case of a 45-yr-old man with multicentric biliary papillomatosis associated with invasive adenocarcinoma of the bile duct is presented. The patient had a 14-yr history of recurrent jaundice and diarrhea. Curettings of the bile ducts, obtained at laparotomy, showed a complex papillary neoplasm containing both adenomatous and mucous-secreting epithelium. One focus of marked epithelial atypia was noted, but no evidence of carcinoma was identified. Wedge liver biopsy disclosed marked bile stasis, portal and periportal fibrosis, cholangitis, and pericholangitis. At autopsy, left, right, and common hepatic ducts were found to contain papillomas. Histological examination of multiple sections of the bile ducts revealed moderate to severe nuclear atypia, mitoses, and multi-layering of epithelial cells in several papillomatous foci; these zones of atypia merged into an area of adenocarcinoma with invasion into the bile duct wall and periductular nerves and the proximal pancreatic duct. No metastases were identified. This case of biliary papillomatosis documents the progression to malignancy of a lesion, which is considered to be benign.

2954 GRANULAR CELL MYOBLASTOMA OF THE COMMON BILE DUCT: REPORT OF A CASE AND REVIEW OF THE LITERATURE. (Eng.) Dursi, J. F.; Hirschl, S.; Gomez, R.; Mersheimer, W. L. (New York Medical Coll., New York, NY). *Rev. Surg.* 32(5):305-310; 1975.

The case of a 35-yr-old woman with granular cell myoblastoma of the common bile duct is presented. Only three cases of granular cell myoblastoma of extrahepatic bile ducts have been published since 1960. The patient presented with a scaling rash and increasing jaundice and anorexia. A transhepatic cholangiogram immediately before operation showed near total obstruction of the common duct; the mass was extirpated, and T-tube drainage was performed. Because of persistent narrowing of the common duct and the nature of granular cell myoblastoma, total excision of the involved area of the common duct was performed 10 weeks later. The patient had complete recovery, without signs of recurrence after 18 months of follow-up. In general, the excision of benign tumors of extrahepatic bile ducts shows increasingly greater operative success.

2955 PRIMARY SCLEROSING CHOLANGITIS: A REPORT OF NINE CASES AND CLINICAL REVIEW. (Eng.) Danzi, J. T.; Makipour, H.; Farmer, R. G. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Am. J. Gastroenterol.* 65(2):109-116; 1976.

ine cases of primary sclerosing cholangitis were eviewed to determine methods of diagnosis, associaion with other disease states, and clinical course f the patients. There were four cases of primary clerosing cholangitis occurring alone, four cases ssociated with inflammatory bowel disease (three ith chronic ulcerative colitis and one case with roctosigmoiditis), and one case associated with orphyria cutanea tarda. All cases of primary clerosing cholangitis occurring alone progressed o secondary biliary cirrhosis; however, none of the ases associated with chronic ulcerative colitis rogressed to secondary biliary cirrhosis. In all ases, the diagnosis was established by operative indings and biopsy results. The patients all resented with slowly progressive jaundice. The oentgenographic correlation of ductal involvement by ndoscopic retrograde cholangiography may enable orrect diagnosis pre-operatively and offer a method or evaluating the disease progression. The classiication of sclerosing cholangitis associated with lcerative colitis, as primary, is discussed. Theraeutic modalities are also discussed, although therapy s mainly empirical.

956 THE CHOLEDOCHOCELE: CORRELATION OF RADIOLOGICAL, CLINICAL AND PATHOLOGICAL FINDINGS.

Eng.) Scholz, F. J.; Carrera, G. F.; Larsen, C. R. Lahey Clinic Foundation, Boston, MA 02115). *Radioogy* 118(1):25-28; 1976.

wo cases of choledochocele are presented, and 14 ases reported in the literature are reviewed. Both atients were older women (59 and 73 yr) with everal years of intermittent biliary colic. The 9-yr-old patient underwent cholecystectomy, but he other patient was previously asymptomatic. Intravenous cholangiogram and upper gastrointestinal eries showed terminal club-like dilatation of the ommon duct, which bulged into the duodenal lumen s a smooth mass. These lesions proved to be bile-filled cysts receiving the common bile duct. Both filled with contrast material during cholangiography but not during the upper gastrointestinal series. The duodenal diverticulum filled on upper gastrointestinal series but not on cholangiography. The duplication cyst did not fill with either method.

2957 GALLBLADDER FUNCTION, CHOLESTEROL STONES, AND BILE COMPOSITION.

(Eng.) Antsaklis, G.; Lewin, M. R.; Sutor, D. J.; Cowie, A. G. A.; Clark, C. G. (Univ. Coll. Hosp. Medical Sch., University St., London WC1, England). *Gut* 16(12): 937-942; 1975.

Patients with pure cholesterol gallstones were investigated to determine a relation between bile composition and gallbladder function. Gallbladder bile, obtained at operation from five patients with no symptoms of biliary disease, was undersaturated with cholesterol in every case. However, gallbladder bile from five patients with stones, composed of 97-100% crystalline cholesterol, was normally saturated with cholesterol when the gallbladder was functioning and undersaturated when it was not. Regardless of gallbladder function, the patients with stones had significantly more cholesterol in their bile than the control group, but the differences between the mean composition of bile from functioning and nonfunctioning gallbladders were not significant. Common duct bile from patients with nonfunctioning and functioning gallbladders was supersaturated with cholesterol, but there was significantly more bile salt and significantly less cholesterol in the bile from patients with nonfunctioning gallbladders. Only in the case of patients with functioning gallbladders did the mean composition of the common duct and gallbladder biles differ significantly. The former contained significantly more cholesterol and less bile salt than the latter. It is suggested that patients with nonfunctioning gallbladders may be "auto-cholecystectomized" with the duct bile reverting to a more "normal" composition.

2958 THE MECHANISM OF INCREASED GALLSTONE FORMATION IN OBESE HUMAN SUBJECTS. (Eng.)

Mabee, T. M.; Meyer, P.; DenBesten, L.; Mason, E. E. (Univ. Iowa Coll. Medicine, Iowa City, IA). *Surgery* 79(4):460-468; 1976.

The hypothesis that obese subjects develop gallstones more frequently than normal subjects because of relative and absolute excess cholesterol excretion in bile was tested by determining the steady-state kinetics of biliary lipid excretion and bile acid pool sizes in eight healthy obese subjects without gallstones. Aliquots of resting gallbladder bile were obtained by aspiration on consecutive days. Hepatic bile excretion was constantly sampled during the infusion of a liquid isocaloric cholesterol-free formula containing a dilution indicator over two 12-hr periods on consecutive days. Gallbladder bile of seven of eight subjects was saturated consistently with cholesterol. Mean hourly hepatic cholesterol excretion in bile was 0.232 mM/hr, three times greater than that of normal subjects and twice that of subjects with gallstones. Phospholipid and bile acid excretion were 0.73 and 1.88 mM/hr, resp. The excretion rates of these cholesterol-solubilizing components of bile are higher than in normal subjects but are insufficient to compensate for the increased cholesterol excretion. The bile acid pool sizes were normal ($\bar{X}$=2.72 g), but the daily synthesis of bile acids was increased ($\bar{X}$=0.86 g of cholic acid). It is concluded that the clinically observed high correlation of cholelithiasis with obesity is due to increased hepatic secretion of cholesterol, which precipitates as cholesterol gallstones.

2959 TRANSIENT OBSTRUCTION OF THE COMMON BILE DUCT FOLLOWING ITS EXPLORATION. (Eng.)

Man, B.; Kraus, L.; Pikielny, S.; Horodniciano, S. (Meir Hosp., Kfar Sava, Israel). *Clin. Radiol.* 27(1):123-127; 1976.

Experience with 163 explorations of the common bile duct is presented, and 4 case studies are reported. Pseudo-obstruction of the bile duct appeared in 21 cases; calculi were found and removed in 16 of these. Intra-operative cholangiography through the T-tube, following exploration of the duct, failed to show contrast material in the duodenum, and a metal catheter passed freely into this area. In all cases, normal emptying was demonstrated in cholangiograms 8-10 days following the operation, and in 6 of these cases, pancreatic duct reflux appeared. No retained stones were disclosed. It is concluded that the obstruction was proximal to the sphincter of Oddi and was caused by spasm and edema of the choledochal sphincter of Boyden. In addition, the obstruction was shown to be transient and not caused by calculus stricture of tumor. The knowledge of possible pseudo-obstruction of the common bile duct, following its exploration, may save the surgeon from unnecessary re-exploration and from performing sphincterotomy or choledochoduodenostomy.

GENERAL

2991 PLASMA TRACE METALS DURING TOTAL PARENTERAL ALIMENTATION. (Eng.) Solomons, N. W.; Layden, T. J.; Rosenberg, I. H.; Vo-Khactu, K.; Sandstead, H. H. (Univ. Chicago, Dept. Medicine, Chicago, IL). *Gastroenterology* 70(6):1022-1025; 1976.

The plasma concentrations of the trace metals zinc and copper were studied prospectively in 13 patients with gastrointestinal diseases treated with parenteral alimentation (TPA) for periods of from 8 days to 7.5 weeks. Plasma copper levels fell rapidly and consistently in all patients with an overall rate of -11 μg/100 ml/week. Zinc concentrations declined in 10 of 13 patients at a more gradual rate, -4.9 μg/100 ml/week. Analysis of the standard parenteral alimentation fluids revealed zinc content equivalent to 50% of the daily requirement (2.2 mg) and a negligible content of copper. Combined analysis of plasma zinc, hair zinc, and taste acuity, revealed that increased utilization or redistribution within the body may affect plasma concentrations in some patients. Neither an increase in urinary excretion nor a primary decrease in plasma binding proteins appeared to be a major factor in lowering plasma trace metal concentrations. These findings indicate that a marked decrease in plasma copper is regular and that a decline in plasma zinc is common during TPA using fluids that are unsupplemented with trace metals. It is recommended that parenteral alimentation fluids be supplemented with the trace metals zinc and copper.

2992 THE EVOLUTION OF ALPHA HEAVY CHAIN DISEASE. (Eng.) Guardia, J.; Rubies-Prat, J.; Gallart, M. T.; Moragas, A.; Martinez-Vazquez, J. M.; Bacardi, R.; Vilaseca, J. (Universidad Autonoma, Barcelona 16, Spain). *Am. J. Med.* 60(4):596-602; 1976.

Case reports of two patients with alpha heavy chain disease are presented, with emphasis on developmental pecularities. In the first patient (28-yr-old man), treatment with 100 mg cyclophosphamide, 20 mg prednisone, and 100 mg doxycycline was associated with a 28-month-long remission and the disappearance of the paraprotein and lymphoplasmocytic infiltration of the intestine. Shortly afterwards, a retroperitoneal immunoblastic lymphoma was found associated with an immunoglobulin G-kappa paraproteinemia and gamma heavy and kappa light chains in the urine. The intestinal biopsy specimen was normal. The patient's condition deteriorated progressively and he died. In the other patient (38-yr-old man), the alpha chain only appeared 2 yr after the malabsorption syndrome. Treatment consisted of tetracycline hydrochlorate (500 mg, 4 times daily) resulting in a rapid improvement in the patient's general condition and elimination of diarrhea, edemas, and hypoproteinemia. The patient was well 9 months later. The progression in the first patient suggests the existence of a B-cell neoplasia of different clone from that which gave rise to the original disease. In the second patient, it is probable that only the increase in the mass of neoplastic cells led to the detection of the protein abnormality, or alternatively, the antigenic oncogenic stimulus led to the abnormal secretion only after 2 yr.

2993 LOPERAMIDE: A NEW ANTIDIARRHEAL AGENT IN THE TREATMENT OF CHRONIC DIARRHEA. (Eng.) Galambos, J. T.; Hersh, T.; Schroder, S.; Wenger, J. (Emory Univ. Sch. Medicine, Atlanta, GA). *Gastroenterology* 70(6):1026-1029; 1976.

The effectiveness and safety of loperamide HCl, as an oral antidiarrheal agent, were investigated in 27 patients (15 men and 12 women) with chronic diarrhea due to Crohn's disease, ulcerative colitis, short bowel syndrome, and idiopathic (functional) causes, in a multiphase study. In the open phase study, loperamide was effective in controlling symptoms of diarrhea in 21 of 27 patients at a median daily dose of four capsules (2 mg each). The average number of daily stools decreased from eight during the relapse period to two stools after 1 month of treatment ($p=0.0001$). Efficacy was confirmed in the double blind (10 patients) and long term open phases of the study. Blood and urine analyses, ECG, and ophthalmic examinations revealed no significant alterations in values and observations which were obtained before and after loperamide therapy. Mean loperamide dosage remained at 8 mg/day for 6-18 months. No tolerance to the antidiarrheal effect was noted. Four patients who were not relieved during therapy discontinued the drug because of abdominal cramping. No other side effects attributable to the drug were observed. It is concluded that loperamide is a safe and effective agent for the treatment of chronic diarrhea.

2994 AN EPIDEMIC OF DIARRHOEA IN HUMAN NEONATES INVOLVING A REOVIRUS-LIKE AGENT AND 'ENTEROPATHOGENIC' SEROTYPES OF Escherichia coli. (Eng.) Bishop, R. F.; Hewstone, A. S.; Davidson, G. P.; Townley, R. R. W.; Holmes, I. H.; Ruck, B. J. (Royal Children's Hosp., Melbourne, Victoria, Australia 3052). *J. Clin. Pathol.* 29(1):46-49; 1976.

An epidemic of diarrhea in 15 of 32 neonates in one hospital is described. Rectal swabs were obtained from 28 of the 32 babies on admission to the ward, from the first baby to develop diarrhea on the day of onset, and from 11 of the other babies 4 days later; swabs were obtained from all 32 babies, 9 days after onset of the outbreak. Specimens were inoculated in various media and in tissue culture. Feces were extracted by differential centrifugation designed to reveal the reovirus-like particle implicated in the etiology of childhood enteritis. Reovirus-like particles were observed, either alone or in association with *Escherichia coli* serotypes, in 8 of the 15 babies with diarrhea and in 3 asymptomatic infants. During the 20 days of the epidemic, *E. coli* $O_{111}B_4$ was grown from the feces of 11 of the 15 babies with diarrhea and from the feces of 5 of the 17 asymptomatic babies. This organism was not identified in feces obtained on admission to the ward. Acquisition of the strain occurred 5-20 days after admission. Seven babies continued to excrete *E. coli* $O_{111}B_4$ for over 10 days after recovery; this usually lasted for 1-3 days. There was no rise in antibody titer to reovirus-like agent in three symptomatic babies infected with the virus. There was a four-fold rise in antibody titer in one asymptomatic baby who was infected with reovirus-like agent. One of the babies infected with *E. coli* $O_{111}B_4$ showed a rise in antibody titer from 1/20 to 1/80; titers from the other babies remained at 1/40. It is concluded that this epidemic was primarily caused by infection with the reovirus-like agent, even though it was not observed in all babies with diarrhea; failure to locate virus in these babies was due to imperfect timing of specimen collection. Because isolation of *E. coli* $O_{111}B_4$ from rectal swabs did not correlate well with the presence and absence of symptomatic illness, and none of the strains produced enterotoxin despite repeated testing, this strain was not implicated in the etiology of the epidemic. The results emphasize that strains of *E. coli* that are isolated from sporadic or epidemic diarrhea should not be assumed to be enteropathogenic on the basis of serotype alone.

2995 ACTIVATION OF INTESTINAL MUCOSAL ADENYLATE CYCLASE BY Shigella dysenteriae I ENTEROTOXIN.

(Eng.) Charney, A. N.; Gots, R. E.; Formal, S. B.; Giannella, R. A. (Walter Reed Army Medical Center, Washington, DC). *Gastroenterology* 70(6): 1085-1090; 1976.

The effect of *Shigella dysenteriae I* enterotoxin on adenylate cyclase activity in rabbit ileal mucosa was studied under various *in vitro* and *in vivo* conditions to study the mechanism by which this toxin induces intestinal secretion. Activation of adenylate cyclase by *Shigella* enterotoxin was observed only when substrate (ATP) concentrations above the Michaelis constant of adenylate cyclase were employed. These concentrations of ATP are greater than those required to demonstrate activation of adenylate cyclase by cholera toxin. Under optimal assay conditions, doses of *Shigella* toxin between 5.4-900 μg of toxin protein and *in vivo* incubation times between 6-18 hr all increased adenylate cyclase activity by about 100%. *Shigella* toxin produced significant but highly variable increases in mucosal cyclic AMP concentrations, which were less than the rises seen with a comparable dose of cholera toxin. This variability in cyclic AMP response to *Shigella* toxin and the disparity between *Shigella* and cholera toxins' effects on mucosal cyclic AMP are probably the result of the different kinetics of adenylate cyclase activated by these enterotoxins. Mucosal Na-K-ATPase activity was unaffected by *Shigella* toxin. These observations suggest that alterations in fluid and electrolyte transport induced by *Shigella* enterotoxin may, in part, be mediated by the adenylate cyclase-cyclic AMP system.

2996 AUTO-IMMUNE ATROPHIC GASTRITIS IN PATIENTS WITH DERMATITIS HERPETIFORMIS.

(Eng.) Stockbrugger, R.; Andersson, H.; Gillberg, R.; Kastrup, W.; Lundquist, G.; Mobacken, H. (Sahlgren's Hosp., Uppsala, Sweden). *Acta Derm-Venereol. (Stockh.)* 56(2):111-113; 1976.

Serum gastrin assay, intragastric bile salt assessment, and gastroscopic examination were undertaken in 17 patients with dermatitis herpetiformis (DH) to determine whether the megaloblastic anemia that appeared occasionally could be due to a lack of gastric intrinsic factor, as in pernicious anemia. Seven patients had achlorhydria. Five of the remaining 10 patients had low secretion of hydrochloric acid. Seven patients, four of whom were achlorhydric, had thyro-gastric antibodies; four were against cytoplasmic thyroidal antigen and five were against parietal cells. The serum gastrin level, which was determined by a radio-immunoabsorbant method, was significantly increased in the achlorhydric patients, compared with the reference group ($p<0.001$) as well as the patients without achlorhydria ($p<0.005$). Biopsy revealed that five patients with achlorhydria and elevated serum gastrin levels had pronounced atrophic gastritis or gastric atrophy of the corpus mucosa. The antral mucosa was normal in four patients and only slightly inflamed in the other patient. The concentration of intragastric bile salts was not increased in the patients studied, indicating that a reflux of bile salts into the stomach is probably not the cause of the gastric atrophy in DH. Atrophic gastritis in these patients probably had an auto-immune pathogenesis, as judged by elevated serum gastrin level, high prevalance of antibodies against parietal cells, and antrum sparing of the gastric atrophy. This type of atrophic gastritis is considered to indicate a precursor state to pernicious anemia.

2997 TRANSMISSIBLE GASTROENTERITIS: MUCOSAL ION TRANSPORT IN ACUTE VIRAL ENTERITIS.

(Eng.) McClung, H. J.; Butler, D. G.; Kerzner, B.; Gall, D. G.; Hamilton, J. R. (Pediatric Gastroenterology Children's Hosp., 561 17th St., Columbus, OH 43205). *Gastroenterology* 70(6):1091-1095; 1976.

Ion tranport in the jejunal mucosa of 14- to 16-day-old piglets with severe diarrhea was studied 40 hr after infection with transmissible gastroenteritis (TGE) virus. In infected pigs Na^+ transport failed to respond normally to glucose when studied either in Ussing short-circuited chambers or in suspensions of enterocytes isolated selectively from jejunal villi. Adding 10 mM theophylline to the chambers produced the same brisk electrical responses and increments in net Cl^- secretion in tissue from both infected and control groups. This defect in glucose-stimulated Na^+ absorption in the acute stage of a viral enteritis probably contributes to the impaired lumen-to-extracellular fluid flux of Na^+, which was found previously in the jejunum of intact TGE-infected pigs. The mechanisms causing diarrhea in this invasive viral enteritis differ from those causing toxigenic diarrhea.

2998 JEJUNAL ADENYLATE CYCLASE ACTIVITY IN HUMAN SUBJECTS DURING VIRAL GASTROENTERITIS.

(Eng.) Levy, A. G.; Widerlite, L.; Schwartz, C. J.; Dolin, R.; Blacklow, N. R.; Gardner, J. D.; Kimberg, D. V.; Trier, J. S. (Natl. Inst. Health, Building 10, Room 9D-15, Bethesda, MD 20014). *Gastroenterology* 70(3):321-325; 1976.

The jejunal adenylate cyclase activity was studied in a total of 23 normal subjects during viral gastroenteritis. The subjects were infected with an inoculum containing Norwalk or Hawaii agent (3.0-5.0 ml). There was a marked interindividual variation in the apparent specific activity of adenylate cyclase in the jejunal tissue obtained by biopsy. Such variation was minimized by expressing enzyme activity as a fraction of maximal that was stimulated by 10^{-2} NaF. Adenylate cyclase activity was not increased during diarrhea or illness in human viral gastroenteritis, suggesting that the adenylate cyclase system has no part in the pathogenesis of diarrhea in this common clinical entity.

2999 LOCAL AND SYSTEMIC CELL-MEDIATED IMMUNITY AGAINST TRANSMISSIBLE GASTROENTERITIS, AN INTESTINAL VIRAL INFECTION OF SWINE.

(Eng.) Frederick, G. T.; Bohl, E. H. (Biology Dept., Rochester

Inst. Technology, Rochester, NY). *J. Immunol.* 116(4):1000-1004; 1976.

The occurrence of local and systemic cell-mediated immunity (CMI) in swine against transmissible gastroenteritis (GE) virus was investigated. Leukocyte suspensions prepared from intestinal lamina propria (LP) and spleen were each incubated with and without inactivated TGE virus. The supernatants from these cultures were tested for the presence of macrophage migration inhibition factor (MIF) by the indirect MIF test, using guinea pig peritoneal exudate cells as the source of macrophages. All swine, which were serologically negative for TGE antibodies (i.e., unexposed to TGE virus) were also negative for MIF. Fourteen of 15 swine p.o. exposed to TGE virus 6-30 days before assaying for CMI gave a positive test for MIF production by both LP and splenic lymphocytes. The 15th animal, p.o. exposed to TGE virus 27 days before assaying, was negative for MIF production by both LP and splenic lymphocytes. In all nine of these exposed animals, where LP and splenic WBC suspensions contained equal numbers of lymphocytes, the percentage of migration inhibition by supernatants from LP preparations was significantly greater ($p \leq 0.01$) than by supernatants from spleen preparations. Two of three animals exposed to TGE virus 7-9.5 months before assaying for CMI were negative for MIF production by lymphocytes from both sources. In all 10 animals given TGE virus s.c., MIF production by splenic lymphocytes was significantly greater ($p<0.01$) than by LP lymphocytes, and in these animals, MIF production by LP lymphocytes was negligible (inhibition of migration<3%). The fact that CMI was detected early after initial exposure to virus indicates that it may play a role in recovery from a primary acute TGE infection.

3000 EFFICACY OF SELECTIVE SPLANCHNIC ARTERIOGRAPHY AND VASOPRESSIN PERFUSION IN DIAGNOSIS AND TREATMENT OF GASTROINTESTINAL HEMORRHAGE.

(Eng.) Johnson, W. C.; Wildrich, W. C. (Boston Veterans Admin. Hosp., 150 South Huntington Ave., Boston, MA 02130). *Am. J. Surg.* 131(4):481-489; 1976.

The effectiveness of selective splanchnic arteriography and vasopressin perfusion in the diagnosis and treatment of 81 bleeding patients was investigated. Patients who were diagnosed by endoscopy to have variceal bleeding from portal hypertension rarely (2 of 49) had a bleeding site that was visualized by angiography. Patients with arterial bleeding had the site determined in 10 of 32 cases. A total of 80% of the variceal bleeding patients who were treated by superior mesenteric artery perfusion with vasopressin had initial control of the gastrointestinal bleeding and 53% did not bleed again after removal of the catheter. This is a significant improvement over the 28% success rate with esophageal tamponade ($p<0.075$). Among 22 patients with a prothrombin level of less than 50%, initial bleeding control was obtained in 68% and final control was achieved in 27%. Of the 49 patients with bleeding due to portal hypertension, 35 died and 14 survived. Uncontrolled bleeding caused 11 deaths. These results suggest that visceral arterial infusion of vasopressin is the method of choice for the short term therapeutic management of massive gastrointestinal bleeding from portal hypertension.

3001 THE ACTION OF TRIGLYCYLVASOPRESSIN ON CONTROL SUBJECTS AND PATIENTS WITH UPPER GASTROINTESTINAL BLEEDING.

(Ger.) Aronsen, K. F.; Wetterlin, S.; Emas, S.; Vojtisek, V.; Mulder, J. L.; Cort, J. H. (Malmo General Hosp., S-21401 Malmo, Sweden). *Klin. Wochenschr.* 53(16):747-753; 1975.

Nα-glycyl-glycyl-glycyl-(8-lysine)-vasopressin, a hormone analogue with prolonged pharmacological action due to slow release of active nonapeptide by *in vivo* enzyme action, was administered to five control subjects and to 14 patients with active upper gastrointestinal bleeding. The control subjects showed a prolonged pressor response to 100 μg/kg of the hormone, associated with a rise in cardiac output, with no ECG signs of myocardial toxicity. Thirteen patients showed pressor responses, hemodynamic and clinical improvement, and clear signs of the cessation of bleeding when 20-100 μg/kg of Nα-glycyl-glycyl-glycyl-(8-lysine)-vasopressin was administered.

3002 JEJUNAL AND ILEAL CALCIUM ABSORPTION IN PATIENTS WITH CHRONIC RENAL DISEASE. EFFECT OF 1α-HYDROXYCHOLECALCIFEROL.

(Eng.) Vergne-Marini, P.; Parker, T. F.; Pak, C. Y. C.; Hull, A. R.; DeLuca, H. F.; Fordtran, J. S. (Univ. Texas Health Science Center, Dallas, TX 75235). *J. Clin. Invest.* 57(4):861-866; 1976.

Calcium absorption in 30-cm segments of small intestine from 26 normal subjects and from 12 patients with end-stage renal disease was measured by constant perfusion of test solutions containing different concentrations of calcium gluconate. In both the jejunum and ileum of the normal subjects, calcium absorption rates increased progressively as luminal calcium concentration was increased stepwise between 1 and 20 mM. Although calcium transport was not saturable within these limits, unidirectional flux ratios of calcium (^{47}Ca) suggest that calcium absorption is active in both the jejunum and ileum. Calcium absorption in the patients with chronic renal disease was markedly depressed in both regions of the small intestine. This was due to decreased flux out of the lumen; flux in the reverse direction was normal. Flux ratios in the renal disease patient showed no evidence of active calcium transport. Treatment of these patients for 1 week with 2 μg/day of 1α-hydroxycholecalciferol [1α-(OH)-D_3] restored net calcium absorption and unidirectional calcium flux out of the lumen to normal values in the jejunum; in the ileum, 1α-(OH)-D_3 increased calcium absorption 60-83% of normal at the various luminal calcium concentrations. 1α-(OH)-D_3 had no effect on unidirectional calcium flux into the lumen or on xylose and electrolyte absorption in either area of the small intestine. The results suggest that 1α-(OH)-D_3 therapy restores active calcium absorption in the jejunum and ileum of patients with chronic renal disease and that it has no effect on passive calcium diffusion from blood to lumen.

3003 GASTROINTESTINAL COMPLICATIONS AFTER RENAL TRANSPLANTATION: PREDICTIVE FACTORS AND MORBIDITY. (Eng.) Owens, M. L.; Wilson, S. E.; Saltzman, R.; Gordon, H. E. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90037). *Arch. Surg. (Chicago)* 111(4):467-471; 1976.

A ten-year study of 109 male patients who underwent renal transplantation was reviewed to identify categories of patients who had the greatest risk of developing gastrointestinal complications. Of the 109 patients, 37 developed gastrointestinal complications. The immediate mortality from these complications was 27%. Of 4 patients with erosive gastritis, 3 died; of the 17 who developed ulcers, 5 died. Emergency surgery for ulcers resulted in two deaths. It appears from this study that patients with peptic ulcer disease, esophagitis, or bleeding before transplantation are much more likely to develop recurrences. It was noted that peptic ulcer complications occurred much more frequently in recipients whose kidneys came from cadavers than from related donors. Experience with gastrointestinal bleeding, or its absence, during a first transplantation is a useful predictor of the results to be achieved after a second transplant. It is concluded that patients with well-documented peptic ulcer disease should either not be accepted for kidney transplantation or should undergo elective surgery for treatment of the ulcer first. Patients in whom ulcer disease develops after a kidney transplant should undergo early elective surgery for this condition. In this series, there was a relative infrequency of intestinal obstruction and intra-abdominal abscess as compared to other studies, perhaps relating to the fact that routine pretransplant splenectomy and bilateral nephrectomy were not performed in the current series.

3004 WATERBORNE TYPHOID FEVER IN DADE COUNTY, FLORIDA: CLINICAL AND THERAPEUTIC EVALUATION OF 105 BACTEREMIC PATIENTS. (Eng.) Hoffman, T. A.; Ruiz, C. J.; Counts, G. W.; Sachs, J. M.; Nitzkin, J. L. (Univ. Miami Sch. Medicine, P.O. Box 520875, Biscayne Annex, Miami, FL 33151). *Am. J. Med.* 59(4):481-487; 1975.

Clinical and therapeutic evaluation during an extensive outbreak of typhoid fever in a migrant worker camp in 1973 are discussed. In 188 cases with proved or presumptive typhoid fever, 105 patients had positive blood cultures for *Salmonella typhi*, 23 had positive stool cultures, 16 had positive serology, 6 had clinical relapse, and 38 cases were presumed to be typhoid. Sustained fever, usually above 38.8 C, was the most common sign in bacteremic patients (93%). Positive blood cultures were obtained in seven afebrile patients. Diarrhea and abdominal pain were more common than constipation as early manifestations. Hepatomegaly was present in 52% of the cases and splenomegaly was present in 42%. Rose spots were seen in only 13%, and bradycardia was infrequent. The WBC was normal in 74%, but SGOT, serum alkaline phosphatase, and LDH were frequently elevated. Gastrointestinal, pulmonary, and neurological complications were uncommon, and circulatory failure was not observed. Treatment consisted of either chloramphenicol (50 mg/kg/day, i.v. or p.o., until defervescence, then 25 mg/kg/day for a total of 14 days) or ampicillin (200 mg/kg/day, i.v., until defervescence, then 50-100 mg/kg/day p.o. for a total of 14 days). Responses to treatment were variable, but the median response time among 68 patients who were treated with chloramphenicol was 2 days less than that in the 34 patients who were treated with ampicillin. There was one possible treatment failure in the ampicillin group. Relapse rates did not differ significantly (10% with chloramphenicol, 3% with ampicillin). Serological studies were of little value since a titer of at least 1:160 was present in 49% of the patients prior to treatment, and only 24% of 57 cases exhibited a fourfold increase in titer. Serologic responses were not significantly different in the two treatment groups. It is suggested that when the infecting organism is sensitive to both antibiotics, ampicillin given parenterally until defervescence and then p.o. for a total of 14 days is a suitable alternative to chloramphenicol for the treatment of acute manifestations of typhoid fever.

3005 ROENTGENOGRAPHIC FINDINGS IN TYPHOID FEVER. (Eng.) Kabakian, H. A.; Nassar, N. T.; Nasrallah, S. M. (American Univ. Beirut Hosp., Beirut, Lebanon). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):198-206; 1975.

Barium meal examinations were performed on the small intestine in 20 patients with proved or clinically suspected typhoid fever. Following ingestion of 550 cm^3 of nonflocculable barium, 20 mg of metoclopramide were administered, i.v., to decrease the transit time through the intestine and to alleviate the severe nausea that some of the patients experienced. Barium reached the colon 1-2.5 hr. About 50% of the patients demonstrated very slight uniform dilatation of the ileum to 1.5 times the normal caliber. There was no jejunal dilatation. Contrary to other reports, no localized dilated segment, excessive secretion, prolonged spasm, or hyperperistalsis was demonstrated. Except for one case, the small intestinal abnormality was confined to the terminal 10-15 cm of the ileum. A total of 16 of 20 patients had a positive blood culture for typhoid fever. In 13 of the 16, roentgenographic changes were demonstrated. All four cases in which a positive culture was not obtained showed positive roentgenographic results. There were no untreated patients with a bacteriologically proved diagnosis in whom the roentgenographic study was negative. In all patients with positive findings. there was clearing of the roentgenographic abnormality following adequate treatment with chloramphenicol. No difference in the abnormality in patients suffering from *Salmonella typhi* or *paratyphi* infection were detected. This study demonstrates definite roentgenographic changes in the intestine associated with typhoid fever. It is suggested that the roentgenographic study may be the only way of confirming the typhoid fever diagnosis, when the clinical picture is suggestive, but the blood culture is negative.

3052 CROHN'S DISEASE OF THE COLON: ANALYSIS OF THE DIAGNOSTIC VALUE OF RADIOLOGY, ENDOSCOPY, AND HISTOLOGY. (Eng.) Meuwissen, S. G. M.; Pape, K. S. S. B.; Agenant, D.; Oushoorn, H. H.; Tytgat, G. N. J. (Div. Gastroenterology, Wilhelmina Gasthuis, Amsterdam, Holland). *Am. J. Dig. Dis.* 21(2):81-88; 1976.

The diagnostic value of radiology, endoscopy, and biopsy in Crohn's disease of the colon was analyzed in 15 patients. Radiologic findings were considered of diagnostic value in only six patients. Characteristic endoscopic lesions were found in 13 patients, and diagnostic histologic features were found in 11. Endoscopy combined with biopsy was diagnostic in all 15 cases. The extent of involvement by endoscopy frequently disagreed with the radiologic assessment, particularly in the rectosigmoid area. Studies in eight patients indicated that sigmoidoscopy and colonoscopy with multiple biopsies provide an accurate alternative to radiology to estimate the extent and severity of the lesions and their evolution during corticosteroid and/or azathioprine treatment.

3053 IMMUNOFLUORESCENCE STUDIES OF GASTRIC HETEROTOPIA OF THE SMALL INTESTINE IN CROHN'S DISEASE. (Eng.) Lechago, J.; Black, C.; Samloff, I. M. (Harbor General Hosp., 1000 West

Carson St., Torrance, CA 90509). *Gastroenterology* 70(3):429-432; 1976.

Immunofluorescence and other morphologic studies were performed on a resected ileum, with extensive areas of pyloric and oxyntic gland metaplasia, from a 49-yr-old woman with Crohn's disease. Most metaplastic glands were of the pyloric type, but numerous oxyntic glands with parietal and chief cells were also observed by light microscopy. The immunofluorescence studies showed that the chief cells contained only the group II pepsinogens. Gastrin-containing or other endocrine cells were not detected in the metaplastic pyloric and oxyntic glands. The latter findings are consistent with the concept that the endocrine and exocrine cells of the gastrointestinal mucosa may originate from different precursor elements during embryogenesis.

3054 SERUM AND INTESTINAL FLUID IMMUNOGLOBULINS AND JEJUNAL IgA SECRETION IN CROHN'S DISEASE.

(Eng.) Jones, E. G.; Beeken, W. L.; Roessner, K. D.; Brown, W. R. (Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Digestion* 14(1): 12-19; 1976.

Immunoglobulins A, G, M, and E in serum and in proximal intestinal fluids and secretion of IgA by cultured jejunal mucosa were measured by radial immunodiffusion or double-antibody radioimmunoassay in 12 healthy subjects and in 36 patients with Crohn's disease. Immunoglobulin concentrations in the serum and intestinal fluids were similar in the patients and the controls, except that serum IgA concentrations in the patients were elevated in comparison with controls (1.85 mg/ml in patients compared to 1.09 in healthy subjects, $p<0.01$). Elevation of IgA and chronicity of the disease were correlated; 12 patients with symptoms for 2 yr or less had levels of 1.64 mg/ml (not significantly different from normal), whereas 19 patients with symptoms of longer duration had 2.09 mg/ml ($p<0.01$). This suggests that the IgA alteration was a response to duration of disease rather than a primary pathogenetic factor. IgA secretion by cultured jejunum was similar in control and patient groups. This suggests that there is no generalized intestinal defect in the secretory IgA system in Crohn's disease.

3055 IMPAIRED ANAMNESTIC CELLULAR IMMUNE RESPONSE IN PATIENTS WITH CROHN' DISEASE.

(Eng.) Meuwissen, S. G. M.; Schellekens, P. T. A.; Huismans, L.; Tytgat, G. N. (Div. Gastroenterology, Wilhelmina Gasthuis and Binnengasthuis, Univ. Amsterdam, Amsterdam, Holland). *Gut* 16(11):854-860; 1975.

The cellular immune system was studied in 54 patients with Crohn's disease (CD) who were not receiving corticosteroids or azathioprine by means of *in vitro* and *in vivo* methods. The *in vitro* lymphocyte reactivity of these patients after stimulation with a cocktail of antigens (varidase, trichophyton, candida, mumps, and purified protein derivative of tuberculin) was significantly depressed when compared with the response of 20 simultaneously cultured healthy controls ($p<0.001$) or a group of 54 separately cultured healthy controls, matched for age and sex ($p<0.001$). The lymphocyte response of a control group of 18 patients with malnutrition or malabsorption, without any evidence of inflammatory bowel disease, was higher than the response of an equal number of CD cases, although the difference failed to reach significance. Intradermal injection of the same five antigens showed a failure to react to any antigen in 13 out of 48 CD patients, in comparison with 3 out of 48 matched healthy controls ($p<0.01$). In both CD patients and in healthy controls, a significant correlation was demonstrated between the number of positive skin tests, the area of skin induration, and the *in vitro* lymphocyte responsiveness after stimulation with the antigen cocktail. In the CD group, no correlation was found between *in vitro* responsiveness and disease activity. The depressed skin reactivity and the hyporesponsiveness in the lymphocyte transformation test, after stimulation by an antigen cocktail, suggest that depression of the anamnestic cellular immune response is a basic feature in patients with Crohn's disease.

3056 ROLE OF THE GRANULOMA IN RECURRENT CROHN'S DISEASE.

(Eng.) Glass, R. E.; Baker, W. N. W. (Gordon Hosp., London, England). *Gut* 17(1): 75-77; 1976.

The relation between the presence of sarcoid-like granulomata in the bowel and associated mesenteric lymph nodes in patients with Crohn's disease and the subsequent course of the disease was investigated in 90 patients during a 5-22 yr followup period. The recurrence rate in the 30 patients without granuloma was almost twice that of the 60 patients with granulomata in their initial operation specimens ($p<0.025$). There were no significant differences between the granulomatous and nongranulomatous patients in sex incidence, of disease recurrence, age at initial presentation, length of history before operation, disease site, pattern of recurrence, type of operation, or occurrence of fulminating disease. In the 18 patients with no sarcoid-like granulomata at primary excision, 9 patients subsequently demonstrated granulomata in their recurrent disease specimens. It is suggested that sarcoid-like granulomata reflect the patients' immune response. It is concluded that granulomatous and nongranulomatous patients do not differ other than in the increased recurrence rate in nongranulomatous disease.

3057 REVERSAL OF GROWTH ARREST IN ADOLESCENTS WITH CROHN'S DISEASE AFTER PARENTERAL ALIMENTATION.

(Eng.) Layden, T.; Rosenberg, J.; Nemchausky, B.; Elson, C.; Rosenberg, I.; (Univ. Chicago, Box 400, 950 E. 59th St., Chicago, IL 60637). *Gastroenterology* 70(6):1017-1021; 1976.

To assess whether a sustained high caloric and nitrogen intake could re-establish growth, four children with extensive Crohn's disease of the small bowel were studied before and after parenteral alimentation, which was instituted for symtomatic disease control. Weight gain, positive nitrogen balance, and improved nutritional status were achieved during parenteral alimentation in each patient. In two 11-yr-old boys, weight gain was sustained using p.o. nutritional supplements, and a substantial increase in linear skeletal growth continued in the ensuing months. One patient, a 17-yr-old boy, entered puberty within 4 months of parenteral alimentation; the fourth patient, a 17-yr-old girl, had the onset of menarche and the development of secondary sex characteristics 4 months after parenteral alimentation and resection of diseased bowel. Growth may be re-established in some growth-arrested children if intake is sufficient to establish a sustained positive caloric and nitrogen balance. Nutritional requirements imposed by the demands of growth and active disease and often compounded by the catabolic effects of corticosteroids may be excessive; growth may occur only if these needs are met orally and/or parenterally.

3058 SERUM GASTRIN RESPONSE TO FOOD STIMULATION AND GASTRIC ACID SECRETION IN MALE PATIENTS WITH ILEAL RESECTION. (Eng.) Gedde-Dahl, D.; Fausa, O. (Natl. Hosp. Norway, Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(7):679-682; 1975.

Gastric acid secretion before and after stimulation with pentagastrin (6 μg/kg, s.c.) and serum gastrin response to a test meal were compared in nine healthy men and in seven men from whom more than 50 cm of the terminal ileum was resected because of Crohn's disease. The mean gastric acid secretion before and after stimulation was not significantly different in the two groups. The mean fasting serum gastrin concentration and the serum gastrin response in absolute values were similar in the two groups (54.7 ± 8.5 pg/ml in Crohn's disease and 42 ± 5.5 pg/ml in controls). The "maximal" acid output-"basal" acid output/"integrated gastrin response" was higher ($p<0.05$), and the gastrin response in relation to fasting level was lower in the patients than in the controls ($p<0.05$). The results indicate that an increased parietal cell sensitivity to gastrin is present after ileal resection. The negative acid feedback mechanism, however, seems to be at work. Under physiological conditions, therefore, the increased sensitivity may not result in acid hypersecretion.

3059 BOWEL MUCOSA IN CROHN'S DISEASE. (Eng.) Ruddell, W. S. J.; Lovell, D.; Blendis, L. M. (Central Middlesex Hosp., London, NW10 7NG, England). *Lancet* 1(7958):539-540; 1976.

3060 PROTEIN PATTERNS IN SERUM AND PERITONEAL FLUID IN CROHN'S DISEASE AND ULCERATIVE COLITIS. (Eng.) Haglund, U.; Hulten, L. (Sahlgren's Hosp., Goteborg, Sweden). *Acta Chir. Scand.* 142(2):160-164; 1976.

3061 ENZYMATIC AND QUANTITATIVE HISTOLOGICAL EVIDENCE FOR CROHN'S DISEASE AS A DIFFUSE LESION OF THE GASTROINTESTINAL TRACT [Abstract]. (Eng.) Dunne, W. T.; Allan, R.; Cooke, W. T. (General Hosp., Birmingham, England). *Gut* 17(5): 399; 1976.

3062 INDUCTION OF GRANULOMA IN CBA AND A_2G STRAIN MICE BY CROHN'S DISEASE TISSUE HOMOGENATES [Abstract]. (Eng.) Cave, D. R.; Mitchell, D. N.; Brooke, B. N. (St. George's Hosp. Medical Sch., London SW17, England). *Gut* 17(5): 400; 1976.

3063 IMMUNE ELECTRON MICROSCOPY FOR VIRAL PARTICLES IN CROHN'S DISEASE [Abstract]. (Eng.) Whorwell, P. J.; Baldwin, R. C.; Wright, R. (Southampton General Hosp., Southampton, England). *Gut* 17(5):399-400; 1976.

3064 THE DEMOGRAPHIC AND SOCIAL CHARACTERISTICS OF PATIENTS WITH CROHN'S DISEASE IN THE NOTTINGHAM AREA. (Eng.) Keighley, A.; Miller, D. S.; Hughes, A. O.; Langman, M. J. S. (Medical Sch., Univ. Nottingham, Nottingham, England). *Scand. J. Gastroenterol.* 11(3):293-296; 1976.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

3065 HISTOENZYMATIC AND ULTRASTRUCTURAL FINDINGS IN THE HUMAN GASTRIC MUCOSA DURING FASTING. (Eng.) Zavicic, M.; Brozman, M.; Jakubovsky, J.; Duris, I.; Koska, M.; Holly, D. (Medical Sch., Komensky Univ., Bratislava, Czechoslovakia). *Gastroenterol. Jpn.* 10(4):261-270; 1975.

The influence of fasting on the structure of the human gastric mucosa was studied using selective histoenzymological and electron microscope methods. Biopsy specimens of the mucosa of seven healthy volunteers were examined after 24-240 hr of fasting. During fasting, an increased acid phosphatase activity in the chief cells of the human fundal mucosa was observed. The activity of the nonspecific esterase (naphtyl esterase) in the chief cells decreased mostly after 240 hr of fasting. A multiplication of lysosomes and narrowing of the granular endoplasmic reticulum was observed in the chief cells during fasting. In some chief cells agglomeration of zymogen granules was seen, while in others only a few granules were observed. In the parietal and other gastric gland cells, steatosis, which attained excessive values, was seen after 72 and 240 hr of fasting. The authors believe that this was due to fasting lipemia. The changes in the mitochondrial structure of the parietal and other gastric mucosa cells were only slightly pronounced. The decreased activity of dehydrogenase in the steatotic parietal cells may be due to the agglomeration of a large amount of lipid drops in the steatotic cells. After 72 and 240 hr of fasting, the parietal cells contained collapsed, underdeveloped intracellular canaliculi and narrowed tubulovesicular profiles, which was probably related to the decreased HCl production. It is concluded that the observed morphological changes result from the decreased function of gastric mucosa cells during fasting, and that these regressive changes are reversible.

3066 HEPATIC ENCEPHALOPATHY AND LIGHT AND ELECTRON MICROGRAPHIC CHANGES OF THE BABOON LIVER AFTER PORTAL DIVERSION. (Eng.) Putnam, C. W.; Porter, K. A.; Starzl, T. E. (Univ. Colorado Medical Center, 4200 East Ninth Ave., Denver, CO 80220). *Ann. Surg.* 184(2):155-161; 1976.

The effects of complete portal diversion were studied in six baboons of varying weights and estimated ages. All animals became emaciated and lost hair. Five animals developed hepatic encephalopathy so serious that it either killed them or required their sacrifice after an average of 109 days. One exceptional animal that lived for 208 days without encephalopathy had markedly elevated blood ammonia levels (443 μg/100 ml, normal<50). In one brain that was examined, greatly increased numbers of Alzeheimer's type II astrocytes were diffusely distributed in the cerebral cortex. Changes in liver function tests were similar to those previously reported in dogs; SGOT, SGPT, and alkaline phosphatase levels were elevated in all animals, while bilirubin remained at normal levels. The livers of all six baboons underwent striking atrophy during the 49-208 days of postoperative observation. With some variations in degree, the observed light and electron microscopic changes (i.e., hepatocyte atrophy and tendency toward fat accumulation, depletion of rough endoplasmic reticulum, and increased number of hepatocytes in mitosis) were the same as those previously seen after complete portacaval shunt diversion in rats, dogs, and humans. Thus, the hepatic injury of Eck fistula is common to all species that have been studied.

3067 MODE OF GROWTH OF THE JEJUNAL CRYPT CELLS OF THE RAT: AN AUTORADIOGRAPHIC STUDY USING DOUBLE LABELLING WITH ^{3}H- AND ^{14}C-THYMIDINE IN LOWER AND UPPER PARTS OF CRYPTS. (Eng.) Burholt, D. R.; Schultze, B.; Maurer, W. (Allegheny General Hosp., 320 East North Ave., Pittsburgh, PA 15212). *Cell Tissue Kinet.* 9(2):107-117; 1976.

The frequency distribution of cells through the mitotic cycle in lower and upper portions of jejunal crypts of the Wistar rat was examined by the ^{3}H-^{14}C-thymidine double labeling technique. Isolated crypts were cut perpendicular to the longitudinal axis so that the percentage of cells in the lower portion varied from 16 to 74%. The lower and upper portion of the same crypts were squashed separately on one microscope slide and the number of ^{3}H- and ^{14}C-only labeled cells were scored to determine the flow rate into and out of S for the two portions. For lower portions of crypts, which contained less than 40% of the total cell number in that crypt, the flow rate into S was about 1.7 times that of the flow rate out of S. As the proportion of cells in the lower part of the crypt increased, the quotient of the flow rate into S divided by the flow rate out of S decreased, and approached the steady state value of 1.0 in lower portions containing 60-74% of the cells. For upper portions of crypts, which contained less than 40% of the total crypt cells, the flow rate into S was about 0.2 times that of the flow rate out of S. The results indicate that in the lower third of the rat jejunal crypts, the frequency distribution of the cells throughout the cycle corresponds to that of an exponentially growing cell population; each mitosis leads to two proliferating daughter cells. The number of cells per unit time at the beginning of the cycle is then double that at the end. In the upper parts of the crypts, the number of cells per unit time is greater at the end of the cycle than at the beginning. In this case, mitotic division predominantly leads to differentiating cells.

3068 THE CYTOLOGICAL EFFECTS OF INFUSION OF LUMINAL POLYETHYLENE GLYCOL ON THE RAT SMALL INTESTINAL MUCOSA. (Eng.) Clarke, R. M.; Kobayashi, S. (Nottingham Univ. Medical Sch., Nottingham, England). *Arch. Histol. Jpn.* 38(2):133-150; 1975.

The cytological effects of infusion of luminal polyethylene glycol (PEG) on the rat small intestinal mucosa were investigated in 17 male albino Wistar rats. An isolated sac of rat upper small intestine was prepared, and its lower end was drained to the skin. Solutions of known volume and composition were infused (4 ml/hr) into the sac, and the intestinal mucosa was examined by light and electron microscopy. Infusion of isosmotic PEG resulted in prompt and progressively severe damage to enterocytes at the top of the villus, while goblet cells and basal granulated cells were apparently unaffected. Thus, after 6-72 hr, a cap of goblet cells and basal granulated cells accumulated at the top of the villus, while the enterocytes underwent vacuolation and disintegration. Infusion of an isosmotic mixture of 1% PEG and 5.1% glucose caused no damage near the site of infusion, but it damaged the intestinal sac further distally. The infusion of distilled water also damaged enterocytes, but the pattern of damage was different from that seen with PEG. Changes were restricted to the upper end of the isolated sac. No abnormality was seen either in the epithelium or the lamina propria of the middle and lower parts of the isolated sac. The most conspicuous feature of the villi at the upper end of the sac was the vacuolation of the apical cytoplasm of the enterocytes. The damage caused by PEG infusion disappeared 6 hr after the replacement of PEG by an infusion of isosmotic glucose solution. It is concluded that this method has potential as a model for the controlled investigation of the mechanism of intestinal epithelial damage in the experimental animal.

ABSORPTION - EXCRETION - TRANSPORT

3077 ABSORPTION OF GALACTOSE BY THE RAT SMALL INTESTINE IN VIVO: PROXIMAL-DISTAL KINETIC GRADIENTS AND A NEW METHOD TO EXPRESS ABSORPTION PER ENTEROCYTE. (Eng.) Batt, R. M.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London, W12 OHS, England). *Clin. Sci. Mol. Med.* 50(6):499-509; 1976.

The *in vivo* absorption of D-galactose by the small intestine was investigated in proximal jejunum and distal ileum in male Wistar rats by use of a recirculation perfusion technique. Multiple sequential perfusions of 64 mmol/l galactose over 4 hr produced no functional or morphological damage in the perfused segments. Absorption of galactose from 8 and 64 mmol/l solutions was independent of flow rate over the range 1.0-6.5 ml/min. Galactose absorption in both the jejunum and the ileum exhibited saturation kinetics of the Michaelis-Menten type. The V_{max} was significantly different ($p<0.001$) for the jejunum and the ileum, although the difference in K_m was not significant ($p=0.07$). The addition of phlorrhizin at concentrations ranging from 10^{-5} to 10^{-2} mol/l, following 64 mmol/l galactose, resulted in a progressive decrease in galactose absorption, until absorption was inhibited by 95% in the jejunum at the highest concentration. Sorbose (64 mmol/l) was absorbed only minimally or not at all in both the jejunum and ileum. Enterocytes were isolated from perfused segments and were quantified by DNA assay with a correction for yield, and the absorptive capacity per enterocyte was calculated. The maximum absorptive capacity per enterocyte was 3.5 times greater in the jejunum than in the ileum. The results agree with previous studies, which assayed the total DNA/cm in intestinal homogenates and determined the proportion of intestinal cells that were mature enterocytes from histological sections.

3078 EVIDENCE FOR TWO DIFFERENT MODES OF TRIPEPTIDE DISAPPEARANCE IN HUMAN INTESTINE: UPTAKE BY PEPTIDE CARRIER SYSTEMS AND HYDROLYSIS BY PEPTIDE HYDROLASES.

(Eng.) Adibi, S. A.; Morse, E. L.; Masilamani, S. S.; Amin, P. M. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15213). *J. Clin. Invest.* 56(6):1355-1363; 1975.

The intestinal fate of triglycine and trileucine was investigated by jejunal perfusion in healthy subjects. Rates of glycine or leucine uptake from test solutions containing triglycine or trileucine were greater than from test solutions containing corresponding amounts of free glycine or free leucine. The rate of glycine uptake from a 100 mM triglycine solution was greater than that from a 150 mM diglycine solution. At each infused load of triglycine (1,000 µmol/min), the rates of either triglycine disappearance (810 ± 40 µM/min/30 cm) or glycine absorption (2,208 ± 122 µM/min/30 cm) were markedly greater than the luminal accumulation rates of either diglycine (56 ± 10 µM/min/30 cm) or free glycine (110 ± 18 µM/min/30 cm). The luminal accumulation rate of free leucine during infusion of a 5 mM trileucine solution was over threefold greater than that of free glycine during the infusion of a 5 mM triglycine solution. Luminal fluid exhibited no hydrolytic activity against triglycine, but contained some activity against trileucine. Saturation of free amino acid carrier system with a large load of leucine (100 mM) did not affect glycine absorption rate from a triglycine test solution, but isoleucine markedly inhibited the uptake of leucine from a trileucine solution. When the carrier system for dipeptides was saturated with 100 mM glycylleucine, the disappearance rate of triglycine was reduced by 66%, while that of trileucine remained unaffected. After addition of glycylleucine to tripeptide solutions, there was a minimal increase in the luminal accumulation of diglycine, while dileucine accumulation was increased by 62-fold. It is concluded that triglycine is taken up intact by human jejunum. This uptake is mediated totally or partially by the carrier system, which also transports dipeptides. In contrast, trileucine is hydrolyzed to leucine and dileucine mostly on the cell surface and a small fraction is hydrolyzed in the gut lumen. These hydrolytic products are then taken up by the free amino acid and dipeptide carrier systems, resp.

3079 VITAMIN D-DEPENDENT, PARTICULATE CALCIUM BINDING ACTIVITY AND INTESTINAL CALCIUM TRANSPORT.

(Eng.) Kowarski, S.; Schachter, D. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *Am. J. Physiol.* 229(5):1198-1204; 1975.

The identification and preliminary biochemical characterization of a new vitamin D-dependent, calcium binding complex (CaBC) of mucosa are described in albino male Sherman rats. The Ca binding activity was sedimented at 140,000 x *g* after treatment of the mucosal particulate fraction with Triton X-114. The Ca binding component was inactivated by heat and repeated freeze thawing and consisted of one or more protein complexes in the range of 0.5-1.0 million mol weight, as indicated by gel filtration. Vitamin D (20,000 IU, s.c. injection) increased the CaBC activity of the duodenal mucosa of deficient rats from 125 ± 16 counts/min/µg to 215 ± 35 ($p<0.002$). Vitamin D also increased the calcium binding protein (CaBP) activity of the duodenal ($p<0.001$) and jejunal ($p<0.001$) mucosa. Maintenance on a diet deficient in Ca strongly stimulated the intestinal Ca-transport mechanism and increased the CaBP in the rat. The mean Ca binding values observed with CaBC preparations from low (0.02%) and high (1.20%) Ca groups, were 75.2 and 54.0 counts/min/µg, resp. ($p<0.01$). The CaBC activity of the duodenal mucosa from young rats significantly exceeded that of the older animals ($p<0.002$). In contrast, the particulate Ca ATPase activity of rat duodenal mucosa did not decrease with age. Duodenal CaBC activity was decreased by cycloheximide from the control values ($p<0.002$). Simultaneously, duodenal CaBP activity was also reduced ($p<0.05$). It is suggested that the component might function in the transit of Ca across the brush border surface to the cytosol of intestinal mucosal cells.

3080 INTESTINAL PERMEABILITY TO LARGE PARTICLES IN NORMAL AND PROTEIN-DEFICIENT ADULT RATS.

(Eng.) Worthington, B. S.; Syrotuck, J. (Child Development and Mental Retardation Center, Univ. Washington, Seattle, WA 98195). *J. Nutr.* 106(1):20-32; 1976.

Intestinal absorption of ferritin and virus particles was assessed in control and protein-deficient rats using light and electron microscopy. Male Sprague-Dawley rats weighing 100-130 g were fed either a 0.5% or 18% lactalbumin diet. At monthly intervals following diet initiation, three rats from each of the two groups received ferritin (molecular weight=650,000, 10 mg/100 ml) or adenovirus type 5 (molecular weight>1,000,000) via ligated jejunal loops either 15 or 30 min prior to loop excision and processing for electron microscopy. Morphological evaluation of jejunal tissues revealed that both control and protein-deficient rats absorbed ferritin and virus particles via pinocytosis, and in both situations, the exogenous particles were believed to be present in lysosomal bodies of typical absorptive cells. Neither ferritin molecules nor virus particles were identified elsewhere in the jejunal mucosa of control rats. However, rats, which were deprived of sufficient dietary protein for 4 months or longer demonstrated exogenous tracer materials in intracellular spaces of the epithelium and lamina propria. Since these severely protein-deprived rats also demonstrated deterioration of apical intercellular junctions, it is possible that large particles moved directly between cells of the epithelial lining and subsequently into underlying connective tissue and vascular compartments for conveyance (as antigens) to other body regions.

3081 STUDIES ON INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE RAT EXOCRINE PANCREAS. IV. STIMULATION BY IN VIVO INFUSION OF CAERULEIN. (Eng.) Bieger, W.; Martin-Achard, A.; Bassler, M.; Kern, H. F. (Dept. Anatomy, D-6900 Heidelberg, Im Neuenheimer Feld 307, W. Germany). *Cell Tissue Res.* 165(4):435-453; 1976.

The effects of prolonged secretory stimulation of the exocrine pancreas by *in vivo* infusion (2 ml/hr) of cerulein (5 x 10^{-8} g/hr) were investigated in male Wistar rats. During the first 6-12 hr of stimulation, Golgi complexes were enlarged and several structural forms of multivesicular bodies were found, indicating a lysosomal degradation of membrane material in the Golgi area. Maximum secretory activity was obtained after a 24-hr infusion; Golgi complexes appeared fragmented and the secretory granules measured only 1/3-1/4 of their normal. In spite of continuous stimulation, the exocrine cells regranulated progressively up to 72 hr infusion. Pancreatic protein synthesis, as measured by the incorporation of tritiated leucine, remained unchanged during the first 6 hr of stimulation, then increased reaching a maximum of 230% of the control levels after 24 hr infusion. After 48 and 72 hr, the rate of protein synthesis decreased again to normal values. Most pronounced changes were observed in the kinetics of intracellular transport of newly synthesized proteins. Using pulse-chase incubation of prestimulated pancreatic lobules, the rate of transition of secretory proteins through the cell increased consistently with prolonged infusion periods reaching maximal acceleration after 24 hr. Newly synthesized proteins were transported and segregated up to 10 times faster than in controls. Enzyme secretion, measured for amylase, followed a similar pattern of stimulation. The results suggest a phasic adaptation of the exocrine pancreatic cell to prolonged stimulation. They demonstrate the possibility of an acceleration of intracellular transport by means of secretagogues.

3082 ACTION OF AMILORIDE ON ELECTROLYTE TRANSPORT OF THE RAT COLON, AND ITS DEPENDENCE ON MINERALOCORTICOIDS. (Ger.) Lange, S.; Veit, C.; Hegel, U.; Gutsche, U. (Klinikum Steglitz, 1 Berlin (West) 45, Hindenburgdamm 30, West Germany). *Endokrinologie* 63(2):271-278; 1974.

An electrolyte solution was instilled into closed segments of the colon descendens and withdrawn 1 hr later to study salt and water transport by the colon of Wistar rats. Control rats absorbed sodium, chloride, and water, and they secreted potassium; amiloride (1 mg/ml) induced the secretion of sodium, chloride, and water. In adrenalectomized rats, colonic transport rates were reduced, and could not be altered by amiloride. The substitution of aldosterone, but not of dexamethasone, enhanced transport rates and restored the reaction of the colonic mucosa to amiloride. These findings may contribute to the understanding of the mechanism of action of amiloride and of mineralocorticoids.

3083 LIPID TRANSPORT ACROSS THE INTESTINAL EPITHELIAL CELL: EFFECT OF COLCHICINE. (Eng.) Arreaza-Plaza, C. A.; Bosch, V.; Otayek, M. A. (Catedra de Patologia General y Fisiopatologia, Facultad de Medicina, Apdo. 50587, Sabana Grande, Venezuela). *Biochim. Biophys. Acta* 431(2):297-302; 1976.

The effect of colchicine on lipid transport across the intestinal epithelial cell was investigated in female Sprague-Dawley rats, which were administered 1 g of emulsified margarine 1 hr after administration of 0.5 mg/100g colchicine. In contrast with control animals, the rats administered colchicine did not show a rise in plasma triacylglycerol concentration. Treatment with 0.5 ml of 20% Triton WR-1339 solution, 2 hours prior to decapitation, produced a marked increase in plasma triacylglycerol concentration in the fasting rat. When Triton WR-1339 was given in conjunction with margarine, the elevation of triacylglycerol concentration in plasma reached higher values than when Triton WR-1339 was given alone ($p<0.001$). Pretreatment with colchicine blocked the margarine-induced rise in triacylglycerol concentration in the presence of Triton WR-1339. The content of triacylglycerol was measured in a jejunal segment after margarine and colchicine treatment. A fivefold increase occurred in the six rats treated with colchicine (20.2 mg/g wet weight, $p<0.001$) as compared with controls. These results are consistent with the idea that colchicine interferes with the intracellular phase of fat absorption, suggesting that the microtubular microfilamentous system may be involved in the release of chylomicrons from the intestinal cell into the circulation.

3084 ACTIVE TRANSPORT IN THE CANINE SMALL INTESTINE FOLLOWING AN ACUTE OCCLUSION. (Fre.) Robinson, J. W. L.; Mirkovitch, V.; Cobo, F.; Menge, H.; Vouron, J. (Hopital Cantonal, CH-1011 Lausanne, Switzerland). *Helv. Chir. Acta* 42(1/2): 123-125; 1975.

3087 GASTRO-OESOPHAGEAL ACID REFLUX AND SPHINCTER PRESSURE IN NORMAL HUMAN SUBJECTS. (Eng.)

Boesby, S. (Odense Univ. Hosp., DK-5000 Odense, Denmark). *Scand. J. Gastroenterol.* 10(7):731-736; 1975.

Twelve-hour continuous recording of pH at the distal end of the esophagus and manometric study of the basal gastro-esophageal sphincter pressure were carried out in 26 normal subjects. Eighteen of the 26 had 1-33 reflux episodes. The duration of each episode was shorter than 15 min in 16 of these 18 subjects. One single reflux episode lasting 15-30 min occurred in two, and one lasting 30-45 min was recorded in one. The total duration of low pH was expressed in percentages of the total time of recording and was dependent upon the criteria used for low pH. On automatic analysis of the course of investigation, pH below 2.3 was found in 5, pH below 3 in 17, and pH below 4 and 5 in 18 of the 26 subjects. Basal gastro-esophageal sphincter pressure fluctuated between 8 and 24 mm Hg. The results suggest that in healthy, asymptomatic individuals, the gastro-esophageal barrier against reflux may be periodically incompetent. If contact between acid gastric contents and the esophageal mucosa is a factor provoking heartburn, low esophageal pH need not necessarily give rise to symptoms; the sensibility to low pH is either individual, or patients with symptoms have considerably more frequent and longer lasting episodes of reflux with low esophageal pH than do normal subjects.

3088 PRESSURE MEASUREMENT IN THE TERMINAL ESOPHAGUS IN HEALTHY BABIES AND INFANTS AGED 3 WEEKS TO 20 MONTHS. (Ger.)

Oesch, A. (Inselspital, Bern, Switzerland). *Helv. Paediatr. Acta* 29(3):251-260; 1974.

Intraluminal pressure in the lower esophagus was measured in 33 infants without esophageal dysfunction, using the open-tip-tube method. In 3-week-old infants, a high pressure profile was found in the area of the gastroesophageal sphincter. The average length of this high pressure profile (9-15 mm) and the average pressure (5-8 mm Hg above that of the fundic portion of the stomach) did not change up to the age of 20 months. These results correspond closely to those found in adults. Both the reflectory relaxation of the gastroesophageal sphincter and the contraction following it found in 24 infants were analogous to those found in adults.

3089 FURTHER STUDIES OF THE ACTION OF CYCLIC AMP ON THE ELECTRICAL AND MECHANICAL ACTIVITIES OF INTESTINAL SMOOTH MUSCLE. (Eng.)

Ohkawa, H. (Yamaguchi Univ. Sch. Medicine, Ube 755, Japan). *Jpn. J. Pharmacol.* 26(2):201-207; 1976.

The effects of externally applied cyclic AMP and other adrenergic stimulants on the electrical and mechanical activities of the cat small intestine were observed by using pressure electrodes. The electrical and mechanical activities were suppressed by 10^{-5} g/ml cyclic AMP and beta stimulants such as 10^{-6} g/ml adrenalin, 10^{-6} g/ml noradrenalin, and 10^{-6} g/ml isopreterenol. The inhibitory actions of cyclic AMP and beta stimulants were potentiated after treatment with 10^{-3} g/ml caffeine, 10^{-4} g/ml theophylline, and 10^{-5} g/ml papaverine, which inhibited the phosphodiesterase activity. The inhibitory action of cyclic AMP and beta stimulants was decreased by 10^{-5} imidazole, an agent that increased phosphodiesterase activity. Exogenously applied concanavalin A, 10^{-7}-10^{-4} g/ml, an agent that inhibits the adenyl cyclase activity, showed no observable changes in both activities, but the effects of beta stimulants were decreased after treatment with concanavalin A. No obvious changes were obtained with cyclic GMP and 10^{-6}-10^{-4} dibutyryl cyclic GMP. These findings tentatively support the hypothesis that cyclic AMP is a second messenger in the inhibitory responses to beta stimulants on the intestinal smooth muscle. It is also concluded that the inhibition of mechanical activity, caused by cyclic AMP, is partially due to suppression of the membrane activity.

3090 RESPONSES TO FIELD STIMULATION OF THE SMOOTH MUSCLE CELL MEMBRANE OF THE GUINEA PIG STOMACH. (Eng.)

Ito, Y.; Kuriyama, H. (Faculty Dentistry, Kyushu Univ., Fukuoka 812, Japan). *Jpn. J. Physiol.* 25(3):333-344; 1975.

The responses of smooth muscle cell membrane of the guinea pig stomach to field stimulation was investigated. In response to a single field stimulation (0.1-0.2 msec), the longitudinal and circular muscles excised from the antrum of the stomach produced a small hyperpolarization that was blocked by treatment with tetrodotoxin (5 x 10^{-7} g/ml). Repetitive stimulation at various frequencies lowered the amplitude of the slow potential change, thus causing suppression of the spike generation and mechanical response. Phentolamine (10^{-7} g/ml) did not suppress the generation of the inhibitory junction potential produced by a single stimulation but it did suppress slightly the hyperpolarization produced by repetitive stimulation. Tetrodotoxin suppressed the amplitude but not the frequency of the slow potential change; however, repetitive field stimulation in the presence of tetrodotoxin did not reduce further the amplitude of the slow potential changes. After a single or repetitive field stimulation was applied, the muscle membrane produced a delayed excitation on the slow potential change. The delayed excitation did not generate in the presence of tetrodotoxin or of atropine (10^{-6} g/ml). Reversal potential level for the inhibitory junction potential was ranged between -80 and -85 mV. Externally applied noradrenalin and ATP suppressed the generation of slow potential changes. Noradrenalin slightly hyperpolarized the membrane and increased the ionic conductance of the membrane, but ATP neither modified the membrane potential nor increased the ionic conductance of the membrane. Although both ATP and noradrenalin are chemical transmitters, the responses observed when these agents were applied externally may not be an accurate representation of those observed in nerve stimulation because of topical differences in the innervation and multiple actions of these chemicals.

3091 STIMULATION OF INTESTINAL SMOOTH MUSCLE BY ATROPINE, PROCAINE, AND TETRODOTOXIN.

(Eng.) Bortoff, A.; Muller, R. (Upstate Medical Center, Syracuse, NY 13210). *Am. J. Physiol.* 229(6):1609-1613; 1975.

The effects of atropine, procaine, and tetrodotoxin (TTX) on the mechanical and electrical activities of several types of cat intestinal smooth muscle preparations were examined. The preparations consisted of isolated rings of intact intestinal wall, intact longitudinal and circular muscle, ganglion-free circular muscle, and ganglion-free circular muscle devoid of its dense layer and plexus muscularis profundus. Atropine and procaine (> 10^{-4} M) stimulated all four types of preparation. At the same dose of atropine, the response of stripped circular muscle was greater than that of intact circular muscle in three out of four and four out of four preparations, resp. On the other hand, TTX (up to 5 x 10^{-6} M) stimulated only the first two preparations. It is concluded that whereas atropine and procaine can directly stimulate intestinal smooth muscle, the excitatory effect of TTX is neurally mediated.

3092 QUANTITATIVE STUDIES OF THE EFFECT OF PANCREATIC GLUCAGON^{+} AND SECRETIN^{++} ON GASTROINTESTINAL MOTILITY IN MAN RECORDED BY SIMULTANEOUS ELECTRO-MANOMETRIC REGISTRATION.

(Ger.) Paul, F. (Med. Hochschule, D-3000 Hannover-Kleefeld, Karl-Wiechert-Allee 9, West Germany). *Klin. Wochenschr.* 52(20):983-989; 1974.

The effect of crystalline pancreatic glucagon and secretin on the motility of the gastrointestinal tract was investigated in 47 subjects without organic gastrointestinal disorders. Simultaneous electromanometric recordings were registered with the aid of microballoons. Secretin (2 Crick-Harper-Raper-U/kg/30 min, i.v.) caused a significant inhibition of the motility phenomena of stomach and duodenum; colonic motility was not influenced. Pancreatic glucagon (0.2 mg/30 min, i.v.) induced an intense suppression of the motility of stomach, proximal small bowel, and colon. It is concluded that in spite of their great structural similarities, both hormones have different sites of action on human gastrointestinal motility. Since pancreatic glucagon inhibits the motility of the proximal and, in contrast to secretin, of the distal gastrointestinal tract as well, it is suggested that this hormone may be used in the treatment of spastic pains originating from the gastrointestinal tract.

3093 THE MOTOR-STIMULATING EFFECT OF NATURAL MOTILIN ON THE LOWER ESOPHAGEAL SPHINCTER, FUNDUS, ANTRUM AHD DUODENUM IN DOGS.

(Eng.) Jennewein, H. M.; Hummelt, H.; Siewert, R.; Waldeck, F. (Abteilung Forschung, C. H. Boehringer Sohn, D-6507 Ingelheim, W. Germany). *Digestion* 13(4):246-250; 1975.

The effect of natural motilin on gastrointestinal motor activity was studied in 10 anesthetized dogs. In single i.v. doses of 10, 30, 100, and 300 ng/kg, and as a continuous infusion (100 ng/kg/hr, 30 min), motilin induced phasic pressure changes in the lower esophageal sphincter (LES) and in the lumen of the fundus, antrum, and duodenum. Tachyphylaxis was seen in six of the dogs. Motilin had no effect on isolated muscle strip preparations of the LES, fundus, antrum, and duodenum in this species, but it is effective on isolated muscle strips from the duodenum and antrum of rabbits and humans. Although the dosages of motilin used were very low (both the single injection and the i.v. infusion), the blood level and motilin effects during endogenous release and exogenous administration should be compared to prove the physiologic activity of motilin.

3094 ACTIONS OF RICINOLEIC ACID AND STRUCTURALLY RELATED FATTY ACIDS ON THE GASTROINTESTINAL TRACT. I. EFFECTS ON SMOOTH MUSCLE CONTRACTILITY IN VITRO.

(Eng.) Stewart, J. J.; Gaginella, T. S.; Bass, P. (Center Health Sciences, Univ. Wisconsin, 425 North Charter St., Madison, WI 53706). *J. Pharmacol. Exp. Ther.* 195(2):347-354; 1975.

Ricinoleic acid and several structurally related compounds were tested for their effects on the smooth muscle contractions of the coaxially stimulated guinea pig ileum, the spontaneously contracting rabbit jejunum, 90 mM potassium depolarized guinea-pig taenia coli, and rat colon. Ricinoleate (1.25 x 10^{-5} to 4 x 10^{-4} M), produced a dose-dependent depression of the stimulated guinea pig ileum. This action was not produced by matching concentrations of oleate, elaidate, linoleate, 12-hydroxystearic acid, 10(9)-hydroxystearate, the methyl ester of ricinoleic acid, or the *trans* isomer, ricinelaidate. Ricinoleyl alcohol was active and, although the depression produced by it took longer to maximize, the dose-response curves for ricinoleate and ricinoleyl alcohol on this tissue were almost superimposable. Ricinoleate showed the same qualitative and quantitative effects on the spontaneously contracting rabbit jejunum, but several differences were noted on the depolarized preparations. Ricinoleate-induced depression of depolarized smooth muscle was much slower in onset and required about 10 times higher concentrations to achieve equivalent responses. The results indicate that ricinoleic acid is not a stimulant or irritant to isolated intestinal smooth muscle.

3095 INHIBITION OF PERISTALSIS IN GUINEA-PIG ISOLATED ILEUM AND COLON BY DRUGS THAT BLOCK PROSTAGLANDIN SYNTHESIS.

(Eng.) Bennett, A.; Eley, K. G.; Stockley, H. L. (King's Coll. Hosp. Medical Sch., London SE5 8RX, England). *Br. J. Pharmacol.* 57(3):335-340; 1976.

Methods of analyzing peristaltic activity were evaluated by use of recordings of longitudinal and circular muscle activity and of propulsion in whole segments of guinea pig ileum and colon. Some prostaglandin synthesis inhibitors and antagonists of prostaglandin action were tested for their suitability for studying the role of prostaglandins in peristalsis. Aspirin (100-200 μg/ml) had no significant effect on submaximal contractions caused by acetylcholine perchlorate (ACh, 4-10 ng/ml), histamine (10 ng/ml), nicotine (1-20 μg/ml), or prostaglandin E_2 (25-300 ng/ml). Indomethacin (1-4 μg/ml) reduced responses to nicotine and prostaglandin E_2. Polyphloretin phosphate (PPP, 40-100 μg/ml) reduced contractions of the longitudinal muscle of guinea pig ileum induced by nicotine (1-20 μg/ml) or prostaglandin E_2 (2-200 ng/ml) but had little effect on responses to ACh (10-100 ng/ml). Aspirin (20-100 μg/ml) or indomethacin (1-4 μg/ml), applied serosally, greatly inhibited all aspects of peristalsis in guinea pig ileum and colon. Inhibition of peristalsis of the ileum by aspirin was antagonized by prostaglandin E_2 (0.1-0.5 μg/ml) and that by indomethacin was removed by prostaglandin $F_{2\alpha}$ (0.3-0.5 μg/ml) or ACh (90.3-1 μg/ml). Inhibition of colonic peristalsis by aspirin (50-100 μg/ml) was antagonized by prostaglandin E_2 but rarely by ACh, and that by indomethacin (0.5-1 μg) was antagonized by prostaglandin E_1 or E_2. Mucosal application of aspirin had little effect on either ileum or colon but indomethacin caused some inhibition. These results support the supposition that prostaglandins contribute to peristaltic activity.

3096 EFFECTS OF AMBIENT AND STAGNANT HYPOXIA ON THE MECHANICAL AND ELECTRICAL ACTIVITY OF THE CANINE UPPER JEJUNUM. (Eng.) Meissner, A.; Bowes, K. L,; Sarna, S. K. (Inst. Hematology, 00957 Warsaw, Poland, Chocimska nr. 5). *Can. J. Surg.* 19(4):316-321; 1976.

The effects of ambient and stagnant hypoxia on the mechanical and electrical activity of the upper jejunum were studied in 32 anesthetized dogs. A 50% or 75% reduction in oxygen content of inhaled air produced ambient hypoxia; superior mesenteric artery (SMA) occlusion or thrombin-induced (150 NIH U/kg) mesenteric thrombosis resulted in stagnant hypoxia. Induction of hypoxia was immediately followed by a transient increase in mechanical activity. A 50% reduction in oxygen content had no other effect. A 75% reduction in oxygen content resulted in a gradual decrease in electrical control activity (ECA) frequency, in the disappearance of electrical response activity (ERA), and in jejunal contractions; however, ECA persisted until cardiac arrest occurred after 30-45 min of hypoxia. Occlusion of the SMA resulted in a significant decrease in contractile activity, but ECA was not affected. Thrombin-induced mesenteric thrombosis produced rapid and irreversible disappearance of both electrical and mechanical activities. Jejunal contractions and ERA are dependent upon an adequate oxygenated blood supply. ECA however, is highly resistant to reduction in oxygen content of perfused blood and it continues until perfusion stops.

SECRETION AND METABOLISM

3103 HISTAMINE-INDUCED HYPOCALCEMIA IN THE RAT. (Eng.) Norberg, H. P.; Schulak, J. A.; Atlas, B.; Kaplan, E. L. (Pritzker Sch. Medicine, Univ. Chicago, Chicago, IL 60636). *Metabolism* 25(2):131-134; 1976.

The effect of histamine and betazole hydrochloride (Histalog) on serum calcium homeostasis was studied in male Holtzman rats. Either histamine base, histamine phosphate, betazole, or the appropriate control solution was injected i.v. into fasted, anesthetized 80-100 g rats. Venous blood was collected before and at 30 and 60 min postinjection. Histamine base (0.5-2.0 mg/rat) induced a significant hypocalcemic response 30 min postinjection; it returned to baseline by 60 min. Likewise, the administration of 1.375 mg/rat of histamine phosphate (equivalent to 0.5 mg histamine base) also resulted in a significant fall in serum calcium concentration. However, betazole administration, in doses as high as 10 mg/rat, did not lower the serum calcium concentration. In the histamine experiments, neither total protein nor hematocrit values differed from control at the time of hypocalcemia. Therefore, the changes in serum calcium concentration cannot be explained by hemodilution. These experiments demonstrate that in the rat the administration of histamine results in a hypocalcemic response similar to that previously observed with gastrin.

3104 EXAMINATION OF BLOOD CAPILLARIES OF THE RAT PAROTID GLAND DURING THREE-HOUR SECRETORY CYCLE. (Rus.) Gusev, S. A. (N. I. Pirogov Second Medical Inst., Moscow, USSR). *Biull. Eksp. Biol. Med.* 80(7):104-106; 1975.

SECRETION AND METABOLISM

Stomach

3106 MAST CELLS AND GASTRIC SECRETION IN THE RAT. (Eng.) Heap, B. J.; Kiernan, J. A. (Dept. Anatomy, Cambridge Univ., Cambridge, England). *Q. J. Exp. Physiol.* 60(4):307-313; 1975.

The relation between mast cells and gastric secretion was investigated in adult female albino Wistar rats deprived of solid food for 48 hr. In control animals, values were obtained for the residual content of acid in the stomach, indicative of the rate of basal secretion, and for the quantities of acid secreted 30 min following injections of 5.0 mg/kg histamine hydrochloride, 250 μg/kg pentagastrin, 100 IU/kg soluble insulin, and 200 μg compound 48/80. The same measurements were determined in groups of rats treated for 5 days with 100-500 μg compound 48/80 (which selectively depleted the whole body of mast cells), and for 3 days with 0.1 mg dexamethasone sodium phosphate (which selectively depleted the gastric mucosa of mast cells). The content of residual acid was depressed to one third of the control value in the 48/80 treated rats, but the additional secretion due to histamine, pentagastrin, or insulin was unaffected. A secretory response to a single injection of compound 48/80 could not be obtained in rats depleted of mast cells. In the dexamethasone treated rats, the residual level of acid was increased to 1.5 times the control value, but the magnitudes of the responses to secretogogues were unchanged. It is concluded that basal secretion of acid into the stomach of the rat is stimulated by histamine derived from mast cells throughout the body, those of the gastric mucosa having no special significance in this respect.

3107 THE INTESTINAL PHASE OF GASTRIC SECRETION: RESPONSE TO LIVER EXTRACT INFUSION INTO THE PROXIMAL JEJUNUM OF HEALTHY HUMAN SUBJECTS. (Eng.) Grabner, P.; Semb, L. S.; Schrumpf, E.; Myren, J. (Diakonhjemmets Hosp., Boks 23, Vinderen, Oslo, Norway). *Scand. J. Gastroenterol.* 11(4):415-419; 1976.

Studies were undertaken to determine whether: (a) gastric secretion increases during perfusion of the proximal jejunum with various substances known to stimulate gastric secretion in animals, (b) perfusion of the proximal jejunum induces changes in serum gastrin level, and (c) interactions occur between endogenous and exogenous gastrin stimulation with jejunal perfusion. A Levine tube was placed under radiological control in the stomach, and a thin polyethylene tube was placed in the proximal jejunum of six healthy volunteers. The stomach and proximal part of jejunum were perfused for 2 hr with 1% acetylcholine, 20% meat extract (Bovril), and 200 ml of 15% liver extract (LE), both alone and in combination with simultaneous infusion of 0.1 μg or 3 μg of exogenous i.v.-administered pentagastrin. A significant increase in serum gastrin concentration was found with antral perfusion of LE only, whereas perfusion of the proximal jejunum did not change the basal level of the serum gastrin concentration. No change from control values was observed in gastric acid and pepsin output on perfusing proximal jejunum with LE alone, or in combination with pentagastrin. Reflux to the stomach varied between 0-1.4%, as determined by addition of radioactive B_{12} to the perfusates. Gastrin was released from the antrum of the stomach by perfusion with 15% LE, but not from the jejunum under the present experimental conditions. Bovril and acetylcholine perfusions did not cause significant responses from the antrum or from the proximal jejunum. The lack of gastric acid response to perfusion of the proximal jejunum in these experiments suggests that the intestinal phase of gastric secretion in man may be different from that observed in other animals.

3108 BIOLOGICAL ACTIVITY OF IODINATED GASTRINS.

(Eng.) Dockray, G. J.; Walsh, J. H.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Biochem. Biophys. Res. Commun.* 69(2):339-345; 1976.

The biological activity of mono- and di-iodo gastrin on acid secretion was studied in two dogs with gastric fistulae. The gastrins were prepared by a minor modification of the chloramine-T reaction and were purified by ion-exchange chromatography. When gastrin was iodinated with ^{125}I, two iodinated products had specific activities of 2,200 and 4,700 cpm/fmol, corresponding to calculated specific activities of mono- and di-iodo heptadecapeptide gastrin, resp. The iodinated gastrins did not differ significantly from unmodified gastrins in immunoreactivity and in stimulating acid secretion in the gastric fistula dogs. The results suggest that under appropriate conditions, iodinated gastrins can be used for binding studies with biological receptors.

3109 THE EFFECT ON GASTRIN SECRETION OF AGENTS WHICH INCREASE THE INTRACELLULAR CONCENTRATION OF 3',5'-ADENOSINE MONOPHOSPHATE.

(Eng.) Hayes, J. R.; Williams, R. H. (Dept. Medicine, Queen's Univ. Belfast, Northern Ireland). *Endocrinology* 97(5):1210-1214; 1975.

An *in vitro* radioimmunoassay technique was used to study the effect of agents known to increase intracellular cyclic AMP (cAMP) levels on gastrin release in male Wistar rats. Isuprel (10^{-5} M), prostaglandin E_1 (10^{-5} M), theophylline (10^{-4} M), and dibutyryl cAMP (5×10^{-4} M) did not affect gastrin release when used alone, but each enhanced arginine-stimulated (0.5 g/100 ml) gastrin release. A biphasic pattern of gastrin release in response to arginine was seen in all experiments. By analysis of variance, the gastrin levels over the initial 7.5 min and over the last 20 min of stimulation were significantly greater than baseline values. Gastrin levels returned to basal concentrations following stimulus withdrawal. The studies emphasize the close functional similarity between the release process of the G cell and that of the B cell of the pancreatic islet.

3110 THE EFFECT OF AN ALDOSTERONE ANTAGONIST ON THE PROTECTIVE ACTION OF CARBENOXOLONE ON THE GASTRIC MUCOSAL BARRIER.

(Eng.) Rees, W. D. W.; Rhodes, J.; Cross, S.; Hole, D. (Univ. Hosp. Wales, Heath Park, Cardiff, U.K.). *J. Pharm. Pharmacol.* 27(12):903-906; 1975.

The effect of spironolactone on the protective action of carbenoxolone sodium on the gastric mucosal barrier was studied in three dogs with Heidenhain pouches. The net fluxes of hydrogen ion and sodium ion were measured before, during, and after contact with a 10 mM bile acid solution at pH 2, in pouches which had not been treated with drugs, in pouches treated with carbenoxolone sodium (30 ml of 0.33% solution for 1 hr daily over 4 weeks), and in pouches treated with both carbenoxolone sodium and spironolactone (0.083% solution for treatment of the pouch, and 25 mg/day, p.o.). Hydrogen ion back diffusion from, and sodium ion gain by the untreated pouch were increased by 10 mM bile acid solution. Addition to the pouches of either carbenoxolone sodium, alone, or carbenoxolone sodium and spironolactone reduced the hydrogen ion back diffusion after exposure to the bile-acid solution. The spironolactone did not change the protective effect of carbenoxolone on the gastric mucosal barrier. Carbenoxolone did not change the increased sodium ion diffusion caused by bile. These results confirm that bile alters the permeability of the mucosal barrier to sodium and hydrogen ions in Heidenhain pouches and that preparation of the pouch with carbenoxolone prevents the increased flux of hydrogen ion that usually follows exposure to bile. Spironolactone did not affect this protective action, suggesting that the mechanisms by which spironolactone reduces ulcer healing are not related to its topical action on the gastric mucosa.

3111 GASTRIC SECRETORY RESPONSE TO DIFFERENT DOSES OF CARBACHOL AND PENTAGASTRIN IN MAN.

(Eng.) Vatn, M. H.; Myren, J. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 11(4):421-425; 1976.

In six healthy subjects, the gastric secretion of acid, pepsin, and intrinsic factor (IF) was measured during 1 hr at basal conditions, and during 1 hr of stimulation with 0.01 μg/kg/hr and thereafter during 1 hr of stimulation with 0.1 μg/kg/hr of pentagastrin. On separate days, the same dose of pentagastrin was given in combination with 0.15 μg/kg/hr or 1.5 μg/kg/hr of carbachol, or stimulation was performed with each of the two doses of carbachol alone. A dose-dependent relation was found between carbachol and the output of acid, pepsin, and IF. The responses to carbachol were independent of changes in plasma gastrin concentration. The acid- and IF-secretions stimulated by the largest dose of pentagastrin were significantly increased by the largest dose of carbachol, whereas the secretion of pepsin was not. It is suggested that pentagastrin and carbachol interact by competitive augmentation on the gastric secretion of acid and IF.

3112 EFFECT OF ALTERATIONS OF BLOOD GLUCOSE LEVELS ON GASTRIC ACID SECRETION, PLASMA GASTRIN, AND PLASMA OSMOLALITY IN MAN.

(Eng.) Stacher, G.; Schulze, D.; Pointner, H.; Landgraf, M. (Psychophysiologisches Laboratorium, Psychiatrische Universitatsklinik, Lazarettgasse 14, 1090 Wien, Austria). *Am. J. Dig. Dis.* 21(7):563-568; 1976.

The effect of alterations of blood glucose levels on gastric acid secretion, plasma gastrin, and plasma osmolality was investigated in 16 experiments on 4 healthy subjects. Each subject underwent four different experimental procedures, each lasting 4 hr. All had in common 1 basal hr and the infusion of

0.2 U/kg/hr insulin in the second hr, but all subjects differed in the time of infusion of 0.66 g/kg/hr glucose or isotonic saline. Acid output was measured continuously by means of intragastric titration and a telemetering capsule, while blood glucose, plasma gastrin, and plasma osmolality were determined in 15-min intervals. During simultaneous infusion of insulin and glucose, during the second hr there was a decrease of acid production with increasing glucose levels. There were highly significant differences ($p<0.001$) for both acid output and blood glucose. In the third and fourth hr, no significant differences between treatments were found for the variables plasma gastrin and osmolality. In the third hr, massive treatment effects were observed for blood glucose ($p<0.001$) and acid output ($p<0.001$). Glucose levels fell sharply after glucose infusion was stopped, but it declined only slightly when glucose administration was continued. By the fourth hr, acid output generally showed inverse tendencies as compared with the glucose levels. The results indicate that there is a definite relation between blood glucose levels and gastric acid secretion. It is suggested that an analagous mechanism, based solely on the blood glucose levels, can be held responsible for the inhibitory effect of glucose on gastric acid secretion in man.

3113 EFFECT OF SECRETIN ON RELEASE OF HETEROGENEOUS FORMS OF GASTRIN.

(Eng.) Straus, E.; Greenstein, A. J.; Yalow, R. S. (Veterans Admin. Hosp., 130 West Kingsbridge Road, Bronx, NY 10468). *Gut* 16(12):999-1005; 1975.

Basal gastrin levels and gastrin responses to i.v. injection of Boots secretin were studied in 22 fasting control subjects. After injection of 1 U Boots secretin/kg, a maximal decrease in gastrin concentration averaging 7 pg/ml was achieved at 10 min. It returned to normal (50 pg/ml) at 1 hr. An i.v. injection of 4 U Boots secretin/kg decreased the gastric concentration to 9 pg/ml at 15 min. Eight of the 22 subjects showed no significant change in gastrin concentration after secretin injection, but there were significant pancreatic responses, as measured by duodenal fluid volume and bicarbonate increases. In three patients with pernicious anemia, secretin injection was followed by a fall in gastrin levels; the minimum was reached in less than 1 hr. In seven subjects given test meals, both with and without prior injection of 4 U Boots secretin/kg, the test meal alone provoked a mean maximal increase from a basal level of 60 pg/ml to 120 pg/ml in 20 min. After secretin injection, the test meal provoked a mean maximal increase of only 30 pg/ml over the initial value. Sephadex G-50 fractionation of fasting plasma samples from 12 control subjects demonstrated that the predominant component was generally big big gastrin (BBG, over 90% in 4 of 12 patients). These four patients had no significant lowering of basal gastrin by secretin injection. Significant depression of the gastrin level after secretin injection was observed only in patients in whom big gastrin (BG) and heptadecapeptide gastrin (HG) were prominent components of the fasting gastrin. These results demonstrate that a bolus injection of secretin is capable of inhibiting gastrin release but that its apparent effect depends upon the distribution of the forms of gastrin in the plasma.

3114 THE INFLUENCE OF SECRETIN ON THE SECRETION OF PEPSIN IN RESPONSE TO ACID STIMULANTS IN THE ANAESTHETIZED CAT.

(Eng.) Braganza, J. M.; Gibbs, A. C. C.; Howat, H. T. (Manchester Royal Infirmary, Manchester, England). *J. Physiol. (Lond.)* 252(3):791-801; 1975.

The effects of cerulein, histamine, and *N*-methyl histamine on peptic secretion was studied in fasting anesthetized cats in which the pylorus and common bile duct were occluded to prevent the release of duodenal hormones that might stimulate or inhibit gastric secretion. Dilute acid was instilled into the stomach at intervals to aid recovery of gastric secretion and to preserve peptic activity. Cerulein (2.5-20 ng/kg/min), histamine (375-1,500 ng/kg/min), and *N*-methyl histamine (375-3,000 ng/kg/min) did not increase the output of pepsin when given alone. Desulfated cerulein was a weak peptic stimulant. Two Crick, Harper, and Raper (C.H.R.) U/kg/hr secretin initiated pancreatic secretion, the volume of which increased progressively as the dose was increased to 32 C.H.R. U/kg/hr. Four C.H.R. U/kg/hr secretin did not increase the output of pepsin. Peptic secretion was stimulated by 8 C.H.R. U/kg/hr. A maximal output of approximately 2,000 U pepsin/15 min was obtained when 16 C.H.R. U/kg/hr was infused. When each acid stimulant was infused along with 4 C.H.R. U/kg/hr secretin, the output of pepsin increased significantly. The peak output, which usually occurred between 15 and 30 min after stimulation, did not exceed 1,000 U pepsin/15 min. It is concluded that the potentiation of the peptic response when an acid stimulant is infused along with a dose of secretin (in itself below the threshold of peptic stimulation) is due to the fact that each acid stimulant increases gastric mucosal blood flow, approximately doubling the effective concentration of secretin delivered to the peptic cell.

3115 EFFECT OF UROGASTRONE ON GASTRIC SECRETION AND PLASMA GASTRIN LEVELS IN NORMAL SUBJECTS.

(Eng.) Elder, J. B.; Ganguli, P. C.; Gillespie, I. E.; Gerring, E. L.; Gregory, H. (Royal Infirmary, Manchester, England). *Gut* 16(11):887-893; 1975.

The effect of urogastrone on gastric acid, pepsin, and intrinsic factor secretion, and on plasma gastrin concentration using pentagastrin, histamine, and insulin as stimulants was investigated in 12 normal men. Clinical, hematological, and biochemical screening tests were conducted throughout the study. Six volunteers received i.v. pentagastrin (0.2 μg/kg/hr) 60-90 min prior to 0.125, 0.25, or 0.5 μg/kg/hr urogastrone. Another six subjects received 0.25 μg/kg/hr urogastrone following injection of 0.2 μg/kg/hr pentagastrin, 10 μg/kg/hr histamine acid phosphate, or 0.2 U/kg/hr soluble insulin. Urogastrone inhibited acid and intrinsic factor secretion whether stimulated by pentagastrin (60%, 85%, and 90% for 0.125, 0.25, and 0.5 μg urogastrone, resp.), histamine (to 40%), or insulin (30%), but it had a much less marked effect on gastric pepsin output. Plasma gastrin levels did not alter significantly. A dose of 0.25 μg urogastrone/kg/hr resulted in inhibition of acid output of 80% and was not associated with clinical side effects. No significant alteration in any of the hematological or biochemical measurements was observed in any of the subjects. The results indicate that urogastrone is an effective inhibitor of acid secretion stimulated by exogenous submaximal pentagastrin and by histamine, and by maximally effective doses of insulin.

3116 THE EFFECT OF SYMPATHETIC NERVE STIMULATION ON SERUM GASTRIN, GASTRIC ACID SECRETION AND MUCOSAL BLOOD FLOW RESPONSES TO MEAT EXTRACT STIMULATION IN ANAESTHETIZED CATS. (Eng.) Blair, E. L.; Grund, E. R.; Reed, J. D.; Sanders, D. J.; Sanger, G.; Shaw, B. (Univ. Newcastle-upon-Tyne Medical Sch., Newcastle-upon-Tyne, NE1 7RU, England). *J. Physiol. (Lond.)* 253(2):493-504; 1975.

The effect of sympathetic nerve stimulation on serum gastrin, gastric acid secretion, and mucosal blood flow (MBF) responses to meat extract stimulation was investigated in the cat. Chloralose anesthetized cats were prepared with fundic and antral pouches. Fundic MBF was measured by the amidopyrine technique and serum gastrin was measured by radioimmunoassay. Meat extract suspension (7.5%) in the antral pouch increased gastric acid output and mucosal blood flow in the fundic pouch during the first 70 min of stimulation. Thereafter, the acid output and mucosal blood flow declined significantly ($p<0.05$). The $\Delta MBF/\Delta H^+$ ratio from the meat extract experiments was not significantly different ($p>0.5$) from the published values for gastrin stimulation under different experimental conditions. The arterial serum gastrin concentration was increased sixfold. Splanchnic nerve stimulation, during responses to meat extract stimulation, produced significant reductions in gastric acid secretion ($p<0.025$), fundic mucosal blood flow ($p<0.02$), arterial serum gastrin concentration ($p<0.01$), and gastrin delivered to the mucosa ($p<0.001$). In the 30-min period following the end of splanchnic nerve stimulation, only arterial serum gastrin concentration remained significantly reduced. The results indicate that in the anesthetized cat, stimulation of the sympathetic nerve supply to the abdomen not only significantly inhibits the fundic acid secretory and mucosal blood flow responses, but it also significantly reduces the rise in serum gastrin concentration produced in response to meat extract suspension in the pyloric antrum.

3117 BIOASSAY OF INHIBITORY ACTIVITY OF GASTRONE ON BASAL HCL SECRETION IN RATS WITH CHRONIC GASTRIC FISTULA. (Eng.) Balanzo, J. T.; Glass, G. B. J. (New York Medical Coll., New York, NY). *Digestion* 13(6):334-343; 1975.

SECRETION AND METABOLISM

Pancreas

3128 FETAL AND NEONATAL RAT PANCREAS IN ORGAN CULTURE: AGE RELATED EFFECTS OF CORTICOSTERONE ON THE ACINAR CELL COMPONENT. (Eng.) McEvoy, R. C.; Hegre, O. D.; Lazarow, A. (Dept. Anatomy, Univ. Minnesota, Minneapolis, MN 55455). *Am. J. Anat.* 146(2):133-150; 1976.

The effects of organ culture, with corticosterone supplementation, on the morphological and biochemical development of the exocrine portion of the rat pancreas at different developmental stages were investigated. Fetal Sprague-Dawley rat pancreas (aged 16-22 days postcoitum) and neonatal pancreas (4 days postnatal) were grown in organ culture (chick embryo extract and rooster serum) either with or without the addition of corticosterone (3×10^{-5} M) for 4 days. Acinar cell differentiation was assessed using quantitative light microscopic linear scanning of tissue sections and enzymatic analysis of amylase in the culture media and in the explants. In the younger fetal tissue of 16 and 18 days postcoitum, exocrine differentiation continued *in vitro*. Supplementation of the media with corticosterone resulted in an enhancement of the *in vitro* acinar cell differentiation in immature fetal explants of both 16 ($p<0.001$) and 18 days ($p<0.001$) postcoitum. The resulting pancreatic cytoarchitecture resembled that of neonatal or adult pancreas with acinar cells comprising 58% of tissue volume. The levels of tissue enzyme activity were still only 10-20% of that attained during a comparable *in vivo* developmental period. The *in vitro* effects of corticosterone on 4-day neonatal tissue included full preservation of explant acinar cell mass and tissue amylase content and 20-fold higher media amylase levels ($p<0.001$). The data suggest that corticosterone can stimulate or maintain the development of normal pancreatic morphology *in vitro*, i.e., promote an adult percentage of light microscopically identifiable acinar cells.

3129 PARASYMPATHETIC INNERVATION AND PANCREATIC SECRETION: THE ROLE OF THE GASTRIC ANTRUM. (Eng.) Rosenberg, I. R.; Zambrano, V. J.; Janowitz, H. D.; Rudick, J. (Mount Sinai Hosp., 11 East 100th St., New York, NY 10029). *Ann. Surg.* 183(3):247-251; 1976.

The role of the antrum on vagally mediated pancreatic secretion was studied in eight conscious dogs prepared with chronic pancreatic and gastric fistulae. After completion of control studies, six animals were subjected to antrectomy, and two were subjected to antroneurolysis (to interrupt submucosal nerve connections); secretory studies were repeated. With the animals secreting in response to secretin (0.3 U/kg/min) or secretin with cholecystokinin (0.05 U/kg/min), the following were administered: (a) insulin, 0.2 U/kg; (b) atropine, 0.2 and 0.4 mg/kg; and (c) insulin after atropine. Insulin hypoglycemia elicited a marked enzyme response. Both antrectomy and antroneurolysis reduced the enzyme response to insulin hypoglycemia by 80%. Atropine (0.2 mg/kg) abolished the insulin response, and at 0.4 mg/kg, it inhibited the enzyme response to cholecystokinin by 50%; these effects were unaltered by antrectomy or antroneurolysis. The experiments suggest that the pancreatic enzyme response to insulin hypoglycemia is predominantly mediated through the vagal release of antral gastrin. Furthermore, antrectomy and antroneurolysis do not affect the enzyme response to cholecystokinin nor do they alter the inhibitory effects of atropine. The inhibition by atropine suggests that a cholinergic background exerts a permissive effect on CCK-mediated enzyme secretion.

3130 DOES HUMAN PANCREAS CONTAIN SALIVARY-TYPE ISOAMYLASE? (Eng.) Shimamura, J.; Fridhandler, L.; Berk, J. E. (Coll. Medicine, Univ. California, Irvine, CA). *Gut* 16(12):1006-1009; 1975.

The isoamylase pattern of normal human pancreatic tissue supernatant was studied by DEAE-Sephadex A-50 chromatography. $CaCl_2$ was omitted from the buffer used during the procedure. Only pancreatic type (P-type) isoamylase was detected at first. However, when effluent fractions were harvested, pooled, concentrated, and rechromatographed, the pancreatic extracts were found to contain salivary type (S-type) amylase, accounting for approximately 0.8-1.7% of the total recovered amylase activity. It is suggested that the recovery of S-type isoamylase in pancreatic extracts may have been caused by penetration of blood filtrates containing amylase, but not hemoglobin, into the intra- or extracellular spaces of the pancreas.

3131 EXOCRINE PANCREAS: EVIDENCE FOR TOPOGRAPHIC PARTITION OF SECRETORY FUNCTION. (Eng.) Malaisse-Lagae, F.; Ravazzola, M.; Robberecht, P.; Vandermeers, A.; Malaisse, W. J.;

Orci, L. (Geneva Univ. Sch. Medicine, Geneva, Switzerland). *Science* 190(4216):795-797; 1975.

The concentration of hydrolases was measured in pancreatic exocrine tissue surrounding the islets of Langerhans (peri-insular halos) and in the tele-insular area of the pancreas from spiny mice (*Acomys cahirinus*) and from normal and diabetic (induced by 40-60 mg/kg streptozotocin, i.v.) mice. The relative concentration of amylase in spiny mice occupied an intermediate position between that of normal and diabetic rats. Among nine computed ratios of tele-insular to peri-insular values for the relative amounts of hydrolases in each animal, seven differed significantly ($p<0.05$ or less). The concentration of amylase relative to that of lipase was invariably higher in the tele-insular than in the peri-insular exocrine tissue in all three, and highly significant differences ($p<0.005$) were found at least once in each animal group. The findings indicate that the precise concentration of each hydrolase in pancreatic juice and its adaptation to environmental factors (e.g., type of food) may be governed, at least partially, by a coordinated participation of hormones emerging from both the gastrointestinal mucosa and the islets of Langerhans and affecting topographically distinct areas of the exocrine pancreas.

3132 ROLE OF CALCIUM IN EXOCRINE PANCREATIC SECRETION. III. COMPARISON OF CALCIUM AND MAGNESIUM MOVEMENTS IN RABBIT PANCREAS.

(Eng.) Schreurs, V. V. A. M.; Swarts, H. G. P.; De Pont, J. J. H. H. M.; Bonting, S. L. (Dept. Biochemistry, Univ. Nijmegen, Nijmegen, Netherlands). *Biochim. Biophys. Acta* 436(3):664-674; 1976.

Calcium and magnesium movements in the isolated rabbit pancreas and in rabbit pancreas fragments were compared qualitatively and quantitatively. At the basal secretion rate, calcium and magnesium were present in the secreted fluid in concentrations of about 30% of their concentrations in the bathing medium. Addition of 10^{-6} M carbachol to the bathing medium resulted in enzyme secretion accompanied by calcium and magnesium release, in divalent cation-free medium as well as in a complete medium. The secretion of each divalent cation was determined to be the sum of two components: an extracellular flux and a flux of protein-associated cations, the so-called secretory flux. The extracellular flux was proportional to the concentration of the divalent cation in the bathing medium. The secretory flux was not dependent upon the presence of the divalent cation in the bathing medium, but it was proportional to the amount of protein secreted. About 25 nmol of each cation was secreted per mg protein. Ca^{2+} and Mg^{2+} were nearly completely separated from the digestive enzymes by gel filtration. They equilibrated completely with their radioactive isotopes, which were added to the sample just before elution, indicating that the cations are rapidly exchangeable after secretion. Efflux studies on rabbit pancreas fragments, pre-loaded with $^{45}Ca^{2+}$, showed a carbachol-stimulated $^{45}Ca^{2+}$ efflux (the stimulatory flux) in addition to a release of amylase. Fragments pre-loaded with $^{28}Mg^{2+}$ did not show carbachol stimulation of the tracer efflux. These studies indicate that calcium and magnesium behave quite similarly with respect to the extracellular and secretory fluxes. The absence of a stimulatory flux for magnesium suggests that the increase of the cytoplasmic calcium concentration plays a specific role in the stimulus-secretion coupling of pancreatic enzyme secretion.

3133 Na^+ DEPENDENCE OF IN VITRO PANCREATIC AMYLASE RELEASE.

(Eng.) Williams, J. A. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Am. J. Physiol.* 229(4):1023-1026; 1975.

The effects of Na^+ on the *in vitro* secretion of amylase from Swiss mice pancreas were studied. Replacement of Na^+ in the medium by Tris, choline, or sucrose blocked the stimulation of amylase release by bethanechol and cerulein, whereas replacement by Li^+ had no effect. The inhibition was rapid and reversible, and stimulated amylase release was linearly related to the log of the Na^+ concentration over the range of 20-100 mM Na^+. Enzyme release stimulated by the Ca^{2+} ionophore A23187 was unaffected by removal of Na^+ from the medium. Tissue and intracellular Na^+ and K^+ contents were unchanged after stimulation of secretion by physiological stimulants. The results suggest that Na^+ may be important in the early steps of stimulus-secretion coupling, leading to the putative rise in intracellular Ca^{2+} that triggers pancreatic enzyme release.

3134 CHYMODENIN, A DUODENAL PEPTIDE: SPECIFIC STIMULATION OF CHYMOTRYPSINOGEN SECRETION.

(Eng.) Adelson, J. W.; Rothman, S. S. (Dept. Physiology, California Univ., San Francisco, CA 94143). *Am. J. Physiol.* 229(6):1680-1686; 1975.

The effect of chymodenin on the secretion of enzymes was investigated *in situ* and *in vitro* in albino male New Zealand rabbit pancreas. A 10^{-8} M injection of chymodenin rapidly increased chymotrypsinogen (ChTg) secretion ($p<0.01$), did not increase lipase secretion, and modestly enhanced protein secretion ($p<0.025$). The increased ChTg output was too rapid to be the result of increased rates or protein synthesis and could not be attributed to the exocytosis of zymogen granule contents because of the enzyme specific nature of the response. In *in vitro* studies, methacholine chloride (1 mg/125 ml bathing solution) was added to the bathing medium of isolated pancreas. Total protein and ChTg outputs were increased four to sevenfold by cholinergic treatment, while lipase output was increased nearly 30-fold ($p<0.05$ for protein versus lipase, and $p<0.01$ for ChTg versus lipase). Regression lines were calculated for individual periods for ChTg and lipase outputs, under control and chymodenin stimulated conditions. The regression lines were each significant at less than the 5% level. The three slopes differed from each other at the $p<0.001$ level (beta chymodenin, 0.898; control, 0.395; and beta methacholine, 0.011). The existence of a duodenal peptide, which produces an enzyme specific response, supports the hypothesis that the secretion of digestive enzymes during digestion is a highly regulated process in which the enzyme content of pancreatic secretion varies according to the composition of intestinal substrates.

3135 EFFECT OF DIETARY PROTEIN ON PROTEOLYTIC ACTIVITIES IN THE PANCREATIC TISSUE AND CONTENTS OF THE SMALL INTESTINE IN RATS. (Eng.) Ikegami, S.; Takai, Y.; Iwao, H. (Natl. Inst. Nutrition, Tokyo, Japan). *J. Nutr. Sci. Vitaminol. (Tokyo)* 21(4):287-295; 1975.

The time courses of proteolytic activities in pancreatic tissue and the contents of the small intestine were determined in male Wistar rats maintained on a diet containing 30% of various proteins, after a switchover from a diet containing 12% casein. The proteolytic activity of the pancreatic tissue quickly responded (within 1-6 days) to change of dietary proteins, with respect to organ weight, nitrogen content, and proteolytic activity, in rats receiving diets containing 30% casein, ovalbumin, lactalbumin, gluten, gelatin, or zein. However, the proteolytic activity in the intestinal contents did not necessarily coincide with the pancreatic digestive function. An approximately threefold increase of enzyme activity was demonstrated on the fifth day of feeding in rats receiving gluten. The proteolytic activity in the intestinal contents returned to the initial level on the eighth day in the gluten fed rats, but rats maintained on a lysine supplemented gluten diet exhibited no such elevation of proteolytic activity. No significant difference in pancreatic composition was shown up to the eighth day in the group receiving gluten alone and in the group receiving the same diet supplemented with lysine under the condition of equally restricted food intake. Intestinal trypsin and chymotrypsin levels were higher in the gluten fed rats, suggesting that the depressed rate of enzyme inactivation in the small intestine may be the principal cause of increased enzyme action in rats receiving gluten.

3136 STUDIES ON INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE RAT EXOCRINE PANCREAS. III. EFFECT OF COBALT, LANTHANUM AND ANTIMYCIN A. (Eng.) Bieger, W.; Seybold, J.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Heidelberg, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 308(4): 329-345; 1975.

The effects of cobalt and lanthanum on the secretory process of the rat exocrine pancreas was studied *in vitro* using isolated pancreatic lobules. Cobalt (10^{-3} to 10^{-5} M) had no effect on the rate of protein synthesis, intracellular transport, or discharge of zymogen granules, if the total population of stored granules was considered. However, it had a marked effect on the release of newly packed zymogen granules that were formed during incubation in 10^{-3} M $CoCl_2$. Determination of specific radioactivity in amylase released under the stimulation of 5×10^{-6} M carbamylcholine and of total proteins retained in the zymogen granule fraction during stimulation indicated that granules formed during incubation in $CoCl_2$ are excluded from discharge. Lanthanum had a differential effect on protein synthesis, intracellular transport, and discharge. Incorporation of tritiated leucine into trichloroacetic acid precipitable proteins was inhibited by 50% at 10^{-3} M $LaCl_3$. Intracellular transport, as studied by cell fractionation, was not changed during the first 35 min post pulse, but was delayed thereafter. This late effect was more pronounced if pancreatic lobules were preincubated for 60 min in 10^{-3} M $LaCl_3$. Discharge of amylase and newly synthesized proteins was inhibited dose-dependently up to 80% by 10^{-3} M $LaCl_3$. The effects of both cobalt and lanthanum were not due to an inhibition of cellular respiration. Comparison of these results with the inhibitory action of antimycin A (10^{-4} to 10^{-8} M) revealed a dose-dependent diminution of the rate of protein synthesis and intracellular transport, while discharge of granules was less energy-dependent. The fine structural appearance of pancreatic lobules after 3 hr incubation in 10^{-3} M $CoCl_2$ was not altered, while in 5×10^{-3} and 10^{-3} M lanthanum acinar lumina were enlarged, and the apical cytoplasm contained large vacuoles. At the highest concentration of lanthanum, a flocculent electron-dense material was apposed to the external lamina of the plasma membrane. Antimycin A led to cellular changes corresponding to the irreversible inhibition of cellular respiration. It is concluded that cobalt acts on the process of granule formation inside the cell, while lanthanum may alter molecules involved in secretagogue binding and transport systems into the cell.

3137 STIMULATED FLOW OF PANCREATIC AND BILIARY SECRETIONS AFTER INTESTINAL EXPOSURE TO CHOLERA TOXIN. (Eng.) Freiman, I.; Melmed, R. N. (Hadassah-University Hosp., P.O. Box 499, Jerusalem, Israel). *Clin. Sci. Mol. Med.* 51(1):81-85; 1976.

The duodeno-jejunal intestinal loops in female albino Wistar rats were perfused with cholera toxin and pancreatic and biliary secretory responses were studied. Cholera toxin (30 µg), dissolved in NaCl, was injected through the proximal catheter into the intestinal loop. An active intestinal secretion of fluid resulted, and it increased gradually to a peak at the 4th hr after exposure to toxin ($p<0.005$) and persisted for an additional 4 hr. Intestinal fluids in the control rats decreased until the 5th hr and remained at a significantly lower volume. There was a progressive increase ($p<0.05$ at the 4th hr, $p<0.01$ at the 5th hr, and $p<0.001$ at the 6th hr) in secretory volume from the pancreatic fistula of the rats exposed to cholera toxin, with a tendency for the protein secretion to fall away after the 7th and 9th hr. Biliary secretion was sustained through the 5th hr in rats exposed to cholera toxin. After this period, there was a progressive reduction of biliary secretion, although a significant difference between the cholera toxin and control groups was maintained through the 6th, 7th, and 8th hr ($p<0.05$). The difference between the mean volume of secretion in the first and last hours was still much lower in the cholera toxin treated group (25%) reduction than in the control group (49%) reduction. The failure of i.v. administered cholera toxin to reproduce the stimulatory pattern of pancreatic and biliary secretion induced by intraluminal choleragen confirms the mediation of mucosal factors in the cholera toxin induced response. It is also suggested that secretion from the pancreas and liver may significantly contribute to the total intestinal secretion in cholera.

SECRETION AND METABOLISM

Hepatobiliary Tract

3141 ^{131}I-ASIALO-α_1-ACID GLYCOPROTEIN. INVESTIGATION OF ITS USE FOR LIVER FUNCTION TESTS; METABOLISM IN THE RAT. (Eng.) van Rijk, P. P.; van den Hamer, C. J. A. (Inst. Nuclear Medicine, Univ. Hosp., Utrecht, Netherlands). *J. Lab. Clin. Med.* 88(1):142-150; 1976.

The *in vivo* behavior of i.v.-administered ^{131}I-asialo-α_1-acid glycoprotein was examined in male Wistar rats to determine whether or not glycoproteins without terminal sialic acid can be used for liver function studies in nuclear medicine. Activity in plasma, liver, and other tissues was measured as a function of time. ^{131}I-asialo-α_1-acid glycoprotein was rapidly removed from the circulation. Five min after injection, only a few percent (0.20-0.26%/ml plasma) of the injected dose remained in the plasma, and 75% was found in the liver, where it was localized in the hepatocytes. However, 15 min after injection, the ^{131}I reappeared in the plasma after the labeled protein had been metabolized by the liver. One hr after injection, less than 5% of the injected dose remained in the liver. Studies with this material in a series of rats using a gammacamera showed the reproducibility of the time-activity curves of the liver. In contrast, the unmodified radioactive α_1-acid glycoprotein disappeared from the blood at a much slower rate. The disappearance curve of the unmodified α_1-acid glycoprotein could be fitted with the sum of two exponential curves with half-times of 2.88 H and 27.3 H, resp. The ^{131}I-α_1-acid glycoprotein did not accumulate in any tissue except the kidneys, and some of the radioactivity was excreted in the urine. It is suggested that the mode of uptake and catabolism of asialo-α_1-acid glycoprotein is most likely by pinocytosis and digestion in the lysosomes. It is concluded that the modified glycoprotein may provide additional information about liver function when used as a diagnostic tool in nuclear medicine.

3142 HUMAN LIVER ACID PHOSPHATASES. (Eng.) Rehkop, D. M.; Van Etten, R. L. (Chemistry Dept., Purdue Univ., West Lafayette, IN). *Hoppe-Seyler's Z. Physiol. Chem.* 356(11):1775-1782; 1975.

The first purification of a soluble acid phosphatase isoenzyme from human liver to a suitable state for kinetic characterization is described. Chromatography of the supernatant of a crude liver homogenate on a calibrated Sephadex G-200 column resulted in the separation of three peaks of enzyme activity (I, II, and III) capable of hydrolyzing *p*-nitrophenyl phosphate (*p*-NPP). Acid phosphatases I, II, and III had molecular weights of 200,000, 107,000, and 13,400, resp. Following partial purification, isoenzyme II was obtained as a single activity band, as assessed by activity staining with *p*-NPP and alpha-naphthyl phosphate on polyacrylamide gels run at several pH values. With 50 mM *p*-NPP as a substrate, enzymes II and III exhibited plateaus of activity over the pH range 3-5 and 3.5-6, resp. Acid phosphatase II was not significantly inhibited by 0.5% formaldehyde. Human liver acid phosphatase II and human prostatic acid phosphatase also exhibited similar activities to substrates that are currently used in the clinical laboratory. Only choline phosphate, which was readily hydrolyzed by human prostatic acid phosphatase, was not hydrolyzed to a detectable extent by human liver acid phosphatase II. Because the acid phosphatase isoenzyme of human liver can be purified to the level of a single phosphatase activity, it is concluded that its kinetic properties can now be characterized meaningfully.

3143 THE HEPATIC TRANSPORT OF TAUROCHOLIC ACID IN THE RAT: DEVELOPMENT OF A MATHEMATICAL MODEL. (Eng.) Iser, J. H.; Packer, J. S.; Smallwood, R. A.; Hoffman, N. E. (Austin Hosp., Heidelberg, Victoria, 3084, Australia). *Clin. Exp. Pharmacol. Physiol.* 3(1):29-36; 1976.

The transport of taurocholic acid (injected at concentrations of 25-12,800 μM) from portal blood to bile was studied in anesthetized male Sprague Dawley rats by injecting a radiolabeled pulse of bile acid. At all concentrations of taurocholic acid, and in all rats, the label was rapidly secreted into the bile. Fifty percent of the dose was secreted in less than 5 min, and the total dose was secreted within 15 min. The mean time to secrete 50% of the dose varied from 2.7 min with 25 μM labeled taurocholate to 3.9 min for a dose that was more than 500-fold greater. There was a statistically significant linear regression of time to secrete 50% dose on dose ($p<0.05$). The observed peak rate of secretion fell from 32.8%/min at 25 μM injectate to 18.8%/min at 12,800 μM injectate. There was a significant regression against dose ($p<0.01$). The time taken to reach this peak rate increased with increasing dose from a mean of 1.6 min to 2.0 min, and the regression was significant ($p<0.05$). The transport process was modeled with both analogue and digital computers. The simplest model that applied to the data comprised rapid uptake from portal blood, slow transport across the cell, and rapid secretion into bile. The digital computer simulation suggested that this model is not unique, but it will require additional testing.

3144 DUODENAL BILE ACIDS IN INFANCY. (Eng.) Challacombe, D. N.; Edkins, S.; Brown, G. A. (Taunton and Somerset Hosp., Musgrove Park Branch, Taunton, Somerset TA1 5DA, England). *Arch. Dis. Child.* 50(11):837-843; 1975.

Duodenal bile acids were estimated in three age groups (birth-2 days, group 1; 2-7 days, group 2; and 10 days-7 months, group 3), and age related changes were demonstrated in infancy. Five bile acids were measured: glycocholic acid (GC), glycine conjugated dihydroxy bile acids (glycochenodeoxycholic acid and glycodeoxycholic acid, GCDC), taurocholic acid (TC), taurine conjugated dihydroxy bile acids (taurochenodeoxycholic acid and taurodeoxycholic acid, TCDC), and taurolithocholic acid (TLC). There were no significant differences among the age groups in total acid concentration obtained at three sampling periods. The overall mean total bile acid concentrations were significantly greater ($p<0.001$) for group 3 than the overall means for both groups 1 and 2. Taurine conjugated bile acids were the only bile acids present in 16 of 33 samples in group 1, and in 8 of 23 samples in group 2, while all samples in group 3 contained taurine conjugates. Glycine conjugated bile acids were the only bile acids present in 1 of 33 samples in group 1, in 4 of 23 samples in group 2, while all samples in group 3 contained glycine conjugates. The trihydroxy:dihydroxy bile acid ratio was similar in all three groups. The deconjugated bile acids, cholic, deoxycholic, chenodeoxycholic, and lithocholic acids, were not detected in any samples. A bile acid spot with a chromatographic mobility identical to the taurolithocholic acid standard was shown in 18 of 33 samples in group 1, in 10 of 23 samples in group 2, and in all 42 samples from group 3. The results indicate qualitative and quantitative changes, which appear to be age related.

3145 ESTIMATION OF BILE ACID EXCRETION IN MAN: COMPARISON OF ISOTOPIC TURNOVER AND FECAL EXCRETION METHODS. (Eng.) Subbiah, M. T. R.; Tyler, N. E.; Buscaglia, D.; Marai, L. (Mayo Clinic, Rochester, MN 55901). *J. Lipid Res.* 17(1):78-84; 1976.

Bile acid excretion was studied in nine human subjects simultaneously by an isotopic turnover method and by fecal chemical analysis during a balance study. The identities of the fecal bile acids were confirmed by combined gas-liquid chromatography/mass spectrometry. Under the steady state conditions of the patient studies, bile acid excretion values obtained by fecal analysis were 18.1-44.2% lower than the values obtained by the isotopic turnover method. This difference persisted even in those patients given $[^{14}C]$chenodeoxycholic acid (15-41 μCi) instead of $[^{3}H]$chenodeoxycholic acid (30-47 μCi). The fecal excretion values were similar when calculated using either β-sitosterol or chromium sesquioxide as fecal flow markers. The fecal excretion values during the earlier part of the isotopic study were higher than those during the latter part of the study in all but two patients. The lower values of bile acid excretion obtained from fecal analysis could not be explained by the loss of bile acids as sulfate conjugates or by losses due to bile acid degradation in the intestine. It is suggested that bile acid turnover is consistently higher than bile acid excretion under experimental conditions. It is recommended that the data obtained from the isotopic turnover method should not be compared with fecal excretion data.

3146 BILIRUBIN CONJUGATES IN BILE OF MAN, RAT AND DOG. SEMI-QUANTITATIVE ANALYSIS OF BILE COMPOSITION BY THIN LAYER CHROMATOGRAPHY. (Eng.) Noir, B. A. (Dept. Gastroenterology, Haedo, Argentina). *Biochem. J.* 155(2):365-373; 1976.

Bilirubin conjugates in the bile of man, rat, and dog were analyzed by semi-quantitative thin-layer chromatography performed on silicic acid, with phenol/water as the developing solvent; the resulting two fractions were further analyzed by separation of the derived ethyl anthranilate azopigments. Homogeneous and mixed hexuronic acid disease of bilirubin, containing glucuronic acid, were found to constitute 51% of the total conjugates in normal rate bile, 45% of those in human post-obstructive bile, and 38% of those in obstructed rat biles. Monoconjugated bilirubin amounted to 33% of total conjugated bile pigments in normal rat bile, and 17%, and 14% in post-obstructive hepatic human bile and gallbladder bile of the dog, resp. After loading with unconjugated bilirubin, a greater amount of monoconjugates (56%) occurred in the rat bile, wherea bilirubin diglucuronide excretion was decreased (34%) In gallbladder bile of the normal dog, 40% of glucose-containing diconjugates, 32% of homogeneous and/or mixed hexuronic acid (mainly glucuronic acid) diesters of bilirubin, and 14% of xylose-containing diconjugates were estimated. Increased amounts of bilirubin conjugates, including some with unidentified uronic acid groups, were observed in cholestatic rat biles, and quantities of conjugates with glucuronic acid were decreased. It is suggested that the biosynthesis of bilirubin glycosides includes at least two enzymatically catalyzed reaction steps: bilirubin → bilirubin monoglycoside → bilirubin diglycoside. The results suggest that high hepatic concentrations of substrate may influence the regulation *in vivo* of the whole conjugation process by stimulating the first step and/or inhibiting the second.

3147 DIURNAL VARIATIONS IN ACTIVITY OF FOUR PYRIDOXAL ENZYMES IN RAT LIVER DURING METABOLIC TRANSITION FROM HIGH CARBOHYDRATE TO HIGH PROTEIN DIET. (Eng.) Yanagi, S.; Campbell, H. A.; Potter, V. R. (Osaka Univ. Medical Sch., 33 Joan-cho, Kita-ku, Osaka 530, Japan). *Life Sci.* 17(9): 1411-1422; 1975.

The diurnal variations in enzyme activities of tyrosine aminotransferase (TAT), ornithine decarboxylase (ODC), ornithine aminotransferase (OAT), and serine dehydratase (SDH) were studied in male Sprague-Dawley rats, which were trained to a 2-hr meal feeding schedule ("2+22") during metabolic transition from 12.5% to 30% to 60% protein diets over a 21-day period. Although the maximal TAT activity on the first day was slightly lower compared with other days, both TAT and ODC activities adapted rapidly to the increased dietary protein from the first day. The responses of TAT and ODC to the food were so rapid that the maximal value was observed only 4 hr after the onset of feeding. After each feeding, ODC activity decreased rapidly after 4 hr, while TAT activity declined only after 6 hr. No clear diurnal rhythm was observed in either OAT or SDH, though OAT activity tended to decrease from the beginning of the dark period and to resume a slow adaptation after about 4 hr. In contrast to ODC and TAT, both OAT and SDH required about 7 days to fully adapt to the high protein diet. The activities of the four enzymes were also compared after four groups of rats had been adapted to the "2+22" feeding of 12.5, 30, and 60% protein diets and to 60% diet, *ad libitum*, resp. The enzyme activities were not directly proportional to the protein content of the diets, although higher activity was observed on the high protein diets. The diurnal variations in both TAT and ODC were observed in all "2+22" groups. The maximal activities of TAT were found earlier in the 12.5 and 30% protein groups than in the 60% protein group. The peak time for ODC activity was found later in the 12.5% protein group than in rats, which were fed 30% and 60% protein. *Ad libitum* rats fed 60% protein maintained relatively high levels of TAT activity, compared to the rats on the "2+22" schedule. However, the maximal activity of ODC on the 60% protein diet *ad libitum* was so low that a diurnal rhythm was not clearly evident. The results suggest that the biochemistry of enzyme synthesis and degradation may be more advantageously studied if diet and behavior are carefully controlled in *in vivo* experiments.

3148 HORSE LIVER ALDEHYDE DEHYDROGENASE: PURIFICATION AND CHARACTERIZATION OF TWO ISOZYMES. (Eng.) Eckfeldt, J.; Mope, L.; Takio, K.; Yonetani, T. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19174). *J. Biol. Chem.* 251(1): 236-240; 1976.

Two isozymes of horse liver aldehyde dehydrogenase (aldehyde, NAD oxidoreductase), F1 and F2, were purified to homogeneity using salt fractionation followed by ion exchange and gel filtration chromatography. The specific activities of the two isozymes in a pH 9.0 system, with propionaldehyde as substrate, were approximately 0.35 and 1.0 μM of NADH/min/mg of protein for the F1 and F2 isozymes, resp. The multiporosity polyacrylamide gel electrophoresis molecular weights of the F1 and F2 isozymes were approximately 230,000 and 240,000, resp. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis gave subunit molecular weight estimates of 52,000 and 53,000 for the F1 and F2 isozymes, resp. The amino acid compositions of the two isozymes were similar; the ionizable amino acid contents were consistent with the electrophoretic and chromatographic behavior of the two isozymes. Both isozymes exhibited a broad aldehyde specificity, oxidizing a wide variety of aliphatic and aromatic aldehydes, and both utilized NAD as coenzyme, but at approximately 300-fold higher coenzyme concentrations both could use NADP. The F1 isozyme exhibited a very low K_m for NAD (3 μM) and a higher K_m for acetaldehyde (70 μM), while the F2 isozyme was found to have a higher K_m for NAD (30 μM) and a low K_m for acetaldehyde (0.2 μM). The two isozymes showed similar chloral hydrate and *p*-chloromercuribenzoate inhibition characteristics, but the F1 isozyme was more sensitive to disulfiram, a physiological inhibitor of acetaldehyde oxidation. Based on its disulfiram inhibition characteristics, it is suggested that the F1 isozyme may be the primary enzyme for oxidizing the acetaldehyde produced during ethanol oxidation *in vivo*.

3149 THE BILIARY EXCRETION OF ^{3}H-MANNITOL AND ^{3}H-IBUTEROL IN UNANAESTHETIZED RATS. (Eng.) Ryrfeldt, A.; Eriksson, H.; Hellstrom, W.; Johansson, M. (Res. Development Labs., AB Draco, S-221 01 Lund, Sweden). *Acta Pharmacol. Toxicol.* 39(1):33-38; 1976.

The biliary clearances of ^{3}H-mannitol (5 and 50 μmol/kg) and ^{3}H-ibuterol (diisobutyrate ester of terbutaline, 0.5 and 5 μmol/kg) after intra-arterial administration were studied in unanesthetized male SPF Sprague-Dawley rats with uninterrupted enterohepatic circulation. The mean bile flow was 0.08 ml/min/kg. The biliary clearance of mannitol ranged from 0.06 to 0.17 ml/min/kg. The biliary clearance of ibuterol and its metabolites (total radioactivity) ranged from 2.05 to 4.81 ml/min/kg, and that of the formed terbutaline ranged from 0.53 to 2.05 ml/min/kg, indicating a concentrative transfer from the plasma to the bile. The cumulative biliary excretion during the 3-hr sampling period amounted to 1% of the administered doses of mannitol and 25% of the doses of ibuterol.

3150 ASSESSMENT OF PROTEIN TURNOVER IN PERFUSED RAT LIVER. EVIDENCE FOR AMINO ACID COMPARTMENTATION FROM DIFFERENTIAL LABELING OF FREE AND tRNA-BOUND VALINE.

(Eng.) Khairallah, E. A.; Mortimore, G. E. (Dept. Biochemistry and Biophysics, Univ. Connecticut, Storrs, CT 06268). *J. Biol. Chem.* 251(5):1375-1384; 1976.

Total protein synthesis in perfused livers of fed male Lewis rats was determined by measuring the rate of valine incorporation based on the specific activity of valine attached to transfer RNA (tRNA). Rates were not significantly altered when perfusate valine was increased from 0.40 to 5 mM and were similar to values calculated earlier from the specific activity of extracellular valine at a concentration of 15 mM. Overall protein degradation, computed from the sum of the rates of synthesis and the total increase of free intra- and extracellular valine, corresponded closely to the increase of free valine that occurred between 5 and 15 min after the addition of cycloheximide. The release of valine from 5 to 15 min was assumed to represent rates of protein degradation in effect prior to the addition of cycloheximide. The close agreement found among these independent assessments of protein metabolism thus appears to eliminate much of the previous uncertainty in the quantitation of hepatic protein turnover. The specific activity of valyl-tRNA attained steady state values that were intermediate between specific activities of the extracellular and intracellular pools but appeared to reach a steady state sooner than that of intracellular valine. The specific activity of valine in tRNA and the intracellular pool was measured in a series of single-pass perfusion experiments; extracellular valine concentration and specific activity were held constant. The intracellular valine specific activity rose with a half-life of 1.2 min. By contrast, the rise in the specific activity of valyl-tRNA was biphasic; the initial phase of the valyl-tRNA curve was rapid, while the second phase had a half-life equal to that of intracellular valine. The data indicate that at physiological concentrations of valine, valyl-tRNA derives its amino acids from both the extracellular and cytoplasmic pools, and that at least some tRNA is charged by extracellular amino acids before they mix with intracellular amino acid pools, possibly from a precursor pool at or near the cell membrane.

3151 APOPROTEINS OF THE LIPOPROTEINS IN A NON-RECIRCULATING PERFUSATE OF RAT LIVER.

(Eng.) Marsh, J. B. (Medical Coll. Pennsylvania, 3300 Henry Ave., Philadelphia, PA 19129). *J. Lipid Res.* 17(1):85-90; 1976.

The apoproteins of serum lipoproteins and of lipoproteins present in a nonrecirculating perfusate of Holtzmann rat liver were compared by immunochemical, gel electrophoretic, and solubility techniques. Serum and perfusate very low density lipoprotein apoprotein compositions were not different. No evidence of lipoprotein resembling serum low density lipoprotein was obtained, but the apoprotein composition of circulatory high density lipoprotein was quantitatively different from the secretory product in the density 1.06-1.21 range. As measured by stained sodium dodecyl sulfate gel electrophoretic patterns, the arginine rich protein was the major secretory apoprotein, while the A-1 protein was the major apoprotein in circulating high density lipoprotein, going from a ratio of 0.3 in serum to 1.7 in the perfusate. A similar pattern was seen in the perfusate of orotic acid-fatty livers. The net release of very low density lipoprotein was 6.6 μg protein/g/hr and of high density lipoprotein, 8.0 μg protein/g/hr, which is 15% and 40%, resp., of the net lipoprotein output of controls. The arginine rich protein isolated from rat serum very low density lipoprotein had a similar amino acid composition to that reported for this protein isolated from rat serum high density lipoprotein. When labeled amino acids were added to the perfusion medium, the arginine rich protein had the highest apparent specific activity at 45 min, and its specific activity was the same in high density lipoprotein as in very low density lipoprotein. The results indicate great similarity between secretory and circulating very low density lipoprotein, no secretion of any lipoprotein resembling low density lipoprotein, and a quantitatively different apoprotein composition of circulatory and secretory high density lipoprotein.

3152 PROPERTIES OF LIVER MITOCHONDRIA FROM IRON-LOADED RATS.

(Eng.) Hanstein, W. G.; Sacks, P. V.; Muller-Eberhard, U. (Scripps Clinic and Res. Foundation, La Jolla, CA 92037). *Biochem. Biophys. Res. Commun.* 67(3):1175-1184; 1975.

The iron content, metabolic performance, and membrane stability of hepatic mitochondria obtained from iron-loaded and dietary anemic male Wistar rats were investigated *in vivo* to determine the effect of alterations of the steady state concentration of iron on the tissue levels of heme and on the metabolic integrity of mitochondria. Iron overload was achieved by injecting i.p. 50 mg iron, 3 times over a 6-day period, while rats were rendered anemic on a complete diet with low (7 ppm) iron content until they were 6 months old. The hepatic iron content ranged from anemic (67%) to normal (100%) to iron-loaded rats (158%). The iron content of liver mitochondria differed by more than one order of magnitude between mitochondria from normal or anemic rats, and mitochondria from iron-loaded rats. In normal mitochondria, there were 3.1 ng atoms iron/mg protein, about 30% of which was heme iron. The content of nonheme iron in liver mitochondria from iron loaded rats was increased from approximately 2 to 31 ng atoms iron/mg protein. This higher level of nonheme iron decreased the respiratory control with pyruvate-malate, but not with 3-hydroxybutyrate or succinate as substrates, and it had no effect on the capacity for phosphorylation and substrate oxidation. Iron-loaded mitochondria malondialdehyde (MDA) levels were about 3 times higher (0.35 nmole/mg protein) than that of control mitochondria, even after repeated washing with bovine serum albumin and EDTA. This suggests that iron is bound inside the mitochondria, to an extent which is 5 times higher than the maximal high affinity binding found *in vitro*. The significant amounts of MDA are indicative of a considerable degree of mitochondria lipid peroxidation.

3153 THE INFLUENCE OF DEHYDROCHOLATE ON HEPATIC UPTAKE AND BILIARY EXCRETION OF ^{3}H-TAUROCHOLATE AND ^{3}H-OUABAIN.

(Eng.) Meijer, D. K. F.; Vonk, R. J.; Scholtens, E. J.; Levine, W. G. (Dept. Pharmacology, State Univ. Groningen, Bloemsingel 1, Groningen, Netherlands). *Drug Metab. Dispos.* 4(1):1-7; 1976.

The hepatic uptake and biliary excretion of ^{3}H-taurocholate and ^{3}H-ouabain was studied in male Wistar rats during saline (control) and constant i.v. dehydrocholate infusions. Dehydrocholate (140 μmol/hr, 25 mg/ml, and 2.3 ml/hr, resp.) did not influence the plasma disappearance or the biliary excretion of taurocholate after a single i.v. injection (37 μmol/kg). Bile production in the dehydrocholate experiment was increased two to threefold compared with controls. The biliary transport maximum for exogenously administered taurocholate was determined by constant infusion to be 135.0 ± 3.0 μmol/hr (22 μmol/min/g of liver). Concomitant infusions of 140 μmol of dehydrocholate per hour did not alter the maximal taurocholate output. The effects of the two bile salts on bile flow were additive. Dehydrocholate (140 μmol/hr) reduced the biliary excretion of ^{3}H-ouabain (0.8 μmol/kg, i.v.) and elevated the secondary slow component of the plasma disappearance of the cardiac glycoside. The hepatic levels of ouabain were increased compared with controls. It is concluded that dehydrocholate interferes with ouabain transport at the canalicular level but not with primary hepatic uptake. Taurocholate (140 μmol/hr) failed to influence the total biliary output of ouabain. These differences and the lack of interaction between dehydrocholate and taurocholate suggest a hepatic transporting pathway for taurocholate that differs from that for dehydrocholate and/or its metabolites.

3154 THE INFLUENCE OF [^{3}H]TAUROCHOLATE ON THE BILIARY EXCRETION OF [^{14}C]ACETYLPROCAINE AMIDE ETHOBROMIDE.

(Eng.) Kuo, S. H.; Johnson, G. E. (645 Keolu Drive, Kailua, HI 96734). *Can. J. Physiol. Pharmacol.* 53(5):888-894; 1975.

The biliary excretion rates of [^{14}C]acetylprocaine amide ethobromide (acetyl-PAEB) and [^{3}H]taurocholate, either administered alone or in combination to adult male Wistar rats, were studied. Their renal pedicles were ligated, and the common bile duct and one jugular vein were cannulated. Acetyl-PAEB (20 mg/kg) and sodium taurocholate (70 mg/kg) were infused through the jugular vein over a 5-min period. Blood and bile samples were collected every 10 min for 60 min. Liver samples were taken at 10 and 20 min. Approximately 100% of the administered taurocholate was excreted within 50 min. The simultaneous administration of acetyl-PAEB did not significantly alter the taurocholate excretion. The amount of the acetyl-PAEB dose excreted in 1 hr was 9.4%. This was increased significantly to 16.5% when taurocholate was given concomitantly. The concentration of acetyl-PAEB in the bile increased significantly 20 min after taurocholate was given (from 391.4 ± 48.0 μg/ml to 1,411 ± 160 μg/ml; $p<0.001$). The ratios of its concentrations in bile-liver and bile-plasma were also increased, but these increases were not statistically significant. Taurocholate did not alter the liver-plasma concentration ratio of acetyl-PAEB. It is suggested that the concomitant administration of taurocholate increased the biliary excretion of acetyl-PAEB by facilitating its secretion by the liver into the bile.

3155 METABOLIC INTERACTION OF ETHANOL AND ALPRENOLOL IN ISOLATED LIVER CELLS.

(Eng.) Grundin, R. (Dept. Forensic Medicine, Karolinska Institutet, S-104 01 Stockholm 60, Sweden). *Acta Pharmacol. Toxicol. (Kbh.)* 37(3):185-200; 1975.

The metabolic interaction of ethanol and alprenolol in isolated Sprague-Dawley rat liver cells was investigated. Alprenolol (0.1 mM) was incubated with isolated rat liver cells suspended to a concentration of 3 x 10^6 cells/ml at increasing concentrations of ethanol (0-40 mM). Inhibition occurred even at low concentrations of ethanol, in a concentration range found *in vivo* during acute intoxication. Ethanol exerted a more pronounced inhibitory effect on alprenolol metabolism, but at concentrations of below 4 mM, an initial slight stimulation of alprenolol metabolism was observed. Ethanol metabolism proceeded at a rate of 13 nmol/min/10^6 cells at a saturation level of ADH. The addition of low concentrations of 4-CH3-pyrazole, a potent inhibitor of alcohol dehydrogenase, caused a marked inhibition of ethanol disappearance in isolated liver cells; almost complete inhibition occurred at 1 mM. Ethanol metabolism in the isolated liver cells was dependent upon cellular reduction level in that the rate of ethanol oxidation at low ethanol concentrations was stimulated approximately 50% by the addition of 250 μM menadion which acted as an endogenous electron acceptor. Ethanol metabolism was also inhibited by pre-incubation of the cells with 10 μM rotenone. Addition of low concentrations of alprenolol (100 μM) or propranolol (100 μM) to incubations of ethanol with isolated liver cells markedly stimulated ethanol disappearance. Hexobarbital (400 μM) also caused stimulation of ethanol metabolism. The results indicate that during simultaneous metabolism of ethanol and alprenolol, at low concentrations of ethanol, electrons can be diverted from the greatly reduced NADH/NAD+ couple by the microsomal mono-oxygenase reaction.

3156 HEPATIC MICROSOMAL ALCOHOL-OXIDIZING SYSTEM IN NORMAL AND ACATALASEMIC MICE: ITS DISSOCIATION FROM THE PEROXIDATIC ACTIVITY OF CATALASE-H_2O_2.

(Eng.) Teschke, R.; Hasumura, Y.; Lieber, C. S. (Veterans Admin. Hosp., Bronx, NY 10468). *Mol. Pharmacol.* 11(6):841-849; 1975.

Various primary alcohols were incubated with hepatic microsomes of both normal (Cs^a) and acatalasemic mice (Cs^b) to assess whether catalase-H_2O_2 is an obligatory component in the microsomal alcohol-oxidizing system. In the presence of an NADPH-generating system washed microsomes (5.0 mg protein) were incubated with 100 mM methanol or 50 mM ethanol, propanol, butanol, or pentanol in phosphate buffer for 5 min before starting the reaction with the NADPH-generating system. These alcohols were metabolized at striking rates by microsomes of both strains (4.9-13.0 nM aldehyde/min/mg microsomal protein for normal mice and 5.13-13.4 nM/min/mg in acatalasemic mice). By contrast, when the NADPH-generating system was replaced by a H_2O_2-producing one, propanol, butanol, and pentanol were not metabolized, indicating that these higher aliphatic alcohols are not substrates for catalase-H_2O_2. Furthermore, mild heat treatment (37 C, 60 min) of microsomes of acatalasemic mice resulted in inactivation of contaminating catalase and virtually abolished alcohol peroxidation of methanol and ethanol by catalase-H_2O_2, whereas the rates of the NADPH-mediated alcohol oxidation by the microsomal fraction persisted with methanol, ethanol, propanol, butanol, and pentanol as substrates. In addition, the microsomal alcohol-oxidizing system of both normal and acatalasemic mice was solubilized and isolated from catalase by DEAE-cellulose column chromatography. These findings dissociate the NADPH-dependent microsomal alcohol-oxidizing system from alcohol peroxidation via catalase-H_2O_2 by difference in substrate specificity and rule out an obligatory involvement of catalase-H_2O_2 in the microsomal system.

3157 MINIMAL HEPATIC CHANGES IN RATS FED ALCOHOL AND A HIGH CASEIN DIET. (Eng.) Patek, A. J., Jr.; Bowry, S. C.; Sabesin, S. M. (Veterans Admin. Hosp., 150 S. Huntington Ave., Boston, MA 02130). *Arch. Pathol. Lab. Med.* 100(1):19-24; 1976.

The effects of prolonged ingestion of alcohol in combination with a nutritious diet on production of hepatic cirrhosis were studied in rats. Thirty-one male Wistar rats were fed a high protein (25%) liquid diet in which alcohol comprised 35.5% of the total calories. Rats maintained on this diet for 19 months had normal growth when compared to 30 rats maintained on chow and water. There was no evidence of cirrhosis after 19 months. Histological examination showed no hepatocellular necrosis, inflammation, or increased connective tissue. Ultrastructural study showed no substantial changes, except for occasional mitochondrial enlargement in cells containing increased lipid. Biochemical analyses at 19 months showed moderate increase in hepatic triglyceride levels and a slight increase in hepatic collagen content in the experimental groups. It is suggested that a nutritious diet may protect against the effects of alcohol.

3158 ALCOHOLIC HEPATOMEGALY: ACCUMULATION OF PROTEIN IN THE LIVER. (Eng.) Baraona, E.; Leo, M. A.; Borowsky, S. A.; Lieber, C. S. (Veterans Admin. Hosp., Bronx, NY 10468). *Science* 190(4216): 794-795; 1975.

The contribution of cell constituents other than fat to ethanol-induced hepatomegaly was investigated. The livers of 24 rats, which were fed a diet containing 36% ethanol for 4-8 weeks increased 30% in both volume and wet weight in comparison with paired littermates, which were fed no ethanol. The increase in liver fat (151 ± 29 mg/100 g body weight) accountec for only half of the increase in liver dry weight (304 ± 40 mg/100 g), and an increase in protein (132 ± 41 mg/100 g) accounted for almost the whole other half. Hepatic protein concentration did not change, indicating that water also increased proportionally. DNA content of the liver remained unchanged, suggesting that hepatomegaly was due to an increase in cell size rather than to increased cell number. The main protein increase occurred in the cytosolic fraction. Increases in hepatic albumin and transferrin concentrations suggest that intrahepatic deposition of export proteins may contribute to this increase in soluble protein and that the feeding of ethanol may decrease the ability of the liver to export proteins.

3159 PROTECTIVE ACTION OF CARNITINE ON LIVER LIPID METABOLISM AFTER ETHANOL ADMINISTRATION IN RATS. (Eng.) Hosein, E. A.; Bexton, B. (Dept. Biochemistry, McGill Univ., Montreal, Quebec H3G 1Y6, Canada). *Biochem. Pharmacol.* 24(20): 1859-1863; 1975.

The capacity of carnitine to restore metabolic balance from that previously altered by ethanol administration was investigated in Sprague-Dawley rats. Two injections of ethanol (4 g/kg, i.p.) produced a significant increase in colonic temperatur 18 hr after administration. Carnitine (0.5 mg/g) did not significantly lower this temperature. Carnitine produced significant protection against increases in SGOT levels in animals receiving ethanol. In animals starved for 2 days, no changes in SGOT levels were observed, but there was an increase in hepatic lipids, indicating that the increase in SGOT, caused by alcohol, is not related to an increase in hepatic lipids. Carnitine (0.1 mg/g) significantly lowered blood triglycerides, but this action occurred with both normal rats and rats receiving alcohol. Higher amounts of carnitine (0.5 mg/g) produced a significan decrease in the liver triglycerides; this was more marked in animals, which received ethanol than in control rats. Similarly, carnitine showed a significant lipotropic action, which was reflected by a diminution of total lipid content in liver; this was also more marked in animals which received ethanol than in controls. The results suggest that carnitine may stimulate metabolism in ethanol-altered mitochondrial membranes.

3160 NORADRENERGIC SUBSENSITIVITY OF RAT LIVER HOMOGENATES DURING CHRONIC ETHANOL INGESTION. (Eng.) French, S. W.; Palmer, D. S.; Narod, M. E. (Dept. Pathology, Univ. British Columbia, Vancouver, V6T1W5, Canada). *Res. Commun. Chem. Pathol. Pharmacol.* 13(2):283-295; 1976.

The cAMP response of liver homogenates of male Wistar rats to norepinephrine (NE) was measured to determine whether noradrenergic receptors in a visceral organ are affected by ethanol feeding. The cAMP response was inhibited after chronic ethanol ingestion (14-17 g/kg/day for 2 weeks) with low (3 x 10^{-5} and 10^{-4} M) concentrations of NE. There was no difference between the ethanol-fed and control values at high concentrations (3×10^{-4}). When the geometric mean ED_{50}'s were calculated, a significant ($p<0.001$) shift to the right of the dose response curve was found. After 3 days of ethanol withdrawal, the cAMP response returned to control levels. The cAMP response of the crude (CM) and purified (PM) mitochondrial fractions was comparable. Addition of NE (10^{-4} M) doubled the cAMP in both CM ($p<0.003$) and PM ($p<0.005$). Phenoxybenzamine (10^{-4} M) did not block the cAMP response of either fraction. Propranolol (10^{-4} M, dl-) inhibited the response of both fractions ($p<0.005$), and chlorpromazine (10^{-5} M) inhibited the response of CM. Practolol (10^{-4} M) also inhibited the response of PM ($p<0.05$). The cAMP response of CM to NaF (10^{-2} M), histamine (10^{-4} M), isoproterenol (10^{-5} M), L-epinephrine (10^{-5} M), and serotonin (10^{-4} M) was significant. The results of the chronic ethanol feeding experiment indicate that NE receptors of the liver become subsensitive just as brain slices did in prior studies.

3161
PROLIFERATION OF ENDOTHELIAL CELLS IN ESTROGEN-STIMULATED RAT LIVER. A LIGHT AND ELECTRON MICROSCOPIC CYTOCHEMICAL STUDY. (Eng.)

Widmann, J.-J.; Fahimi, H. D. (Harvard Medical Sch., Boston, MA). *Lab. Invest.* 34(2):141-149; 1976.

The mononuclear phagocytes (Kupffer cells) were used as cellular markers to determine the effects of an estrogen upon the mitotic activity and the ultrastructure of individual types of littoral cells in the liver of female Charles River rats. The rats received a single 10-mg injection of diethylstilbesterol, and at daily intervals up to 6 days their livers were fixed by perfusion and processed for localization of peroxidase. Mitotic figures were rare in untreated control animals, but dividing littoral cells with both positive and negative peroxidase reaction were identified. The exclusive reaction identified the Kupffer cells not only in the interphase but also during the mitotic division. In estrogen-treated animals, there was a sharp rise in the mitotic activity of littoral cells; the activity reached its peak on the third day and returned to normal levels on the sixth day after the initial injection. A breakdown of the dividing cells, on the basis of their peroxidase reactivity, revealed that nearly the entire population of dividing cells consisted of peroxidase-negative endothelial cells. In addition, numerous hyperactive Kupffer cells containing large phagolysosomes with phagocytosed peripheral blood cells and latex particles were seen. Intermediate cell-types with cytochemical features between Kupffer cells and endothelial cells or between monocytes and Kupffer cells were not encountered. Because of the limited phagocytic capacity of hepatic endothelial cells, these observations provide morphologic evidence that estrogen treatment has little or no effect upon the particle clearing function of the reticuloendothelial system in rats. The rare but clear demonstration of dividing Kupffer cells in liver sinusoids indicates that these cells are capable of self-replication *in situ*. In addition it is suggested that the estrogens may play an important role in the pathophysiology of endothelial cells.

3162
EXPERIMENTAL GALACTOSAMINE INDUCED HEPATITIS: EFFECT OF ANTICOAGULANT AND ANTIFIBRINOLYTIC AGENTS ON MICROCLOT FORMATION. (Eng.)

Muller-Berghaus, G.; Reuter, C.; Bleyl, U. (Dept. Medicine, Justus Liebig Universitat, Klinikstrasse 36, 63 Giessen, Germany). *Am. J. Pathol.* 82(2):393-406; 1976.

The effect of an antifibrinolytic agent (epsilon-aminocaproic acid, EACA) and an anticoagulant (heparin) on microclot formation in rabbits of mixed New Zealand breeds was investigated to determine the severity of liver damage. An experimental hepatitis was induced by i.v. infusion of 1 g galactosamine/kg body weight. This caused major pathological changes in the livers of 9 out of 10 animals. Galactosamine also triggered formation of glomerular microclots in 2 out of 10 rabbits and numerous microclots in the interalveolar capillaries of 3 out of 10 rabbits. The infusion of 0.5 g EACA/kg/hr caused the formation of microclots in the renal glomerular capillaries of 9 out of 12 rabbits and in the lungs of 3 animals. The microclots exhibited typical staining characteristics like those observed in the generalized Shwartzman reaction. Some animals developed bilateral renal cortical necrosis. Animals treated with 1500 U/kg heparin, immediately before galactosamine and EACA or with a continuous infusion (750 U/kg/hr) after galactosamine did not develop any microclots in either the renal glomerular capillaries or in the liver. A few microclots were seen in the lungs and the spleen. Increases in SGOT and bilirubin levels were similar in heparin-treated and untreated rabbits. The results indicate that disseminated intravascular coagulation is involved in galactosamine-induced hepatitis but that it does not contribute to the severity of the liver injury.

3163
EFFECT OF LIPOSOMAL ENTRAPMENT ON THE PROTECTIVE ACTION OF GLUTATHIONE AGAINST PARACETAMOL-INDUCED LIVER NECROSIS [Abstract]. (Eng.)

Malnoe, A.; Louis, A.; Benedetti, M. S.; Schneider, M.; Smith, R. L.; Kreber, L.; Lam, R. (Battelle, Geneva Res. Centre, 7 Route de Drize, 1227 Carouge/Geneva, Switzerland). *Biochem. Soc. Trans.* 3(5):730-732; 1975.

The use of liposomes as carriers of agents that protect against drug-induced liver damage was studied in male Swiss albino mice using glutathione as the protective agent. Mice injected i.p. with paracetamol (500 mg/kg, i.p.) developed liver necrosis, as evidenced by a large increase in plasma aspartate aminotransferase and alanine aminotransferase. The administration of either four doses of glutathione each of 128 mg/kg at 15, 45, 75, and 105 min after paracetamol or of a single large dose (500 and 800 mg/kg) significantly protected against the hepatotoxic effects. Glutathione entrapped in liposomes was much less effective than the free drug in decreasing the hepatotoxic effects of paracetamol. The i.v. injection of entrapped glutathione in four separated doses at 15, 45, 75, and 105 min before paracetamol failed to give significant protection, indicating that the failure of encapsulated drug to produce protection was not due to its slow release from the liposome. The results suggest that entrapped glutathione fails to protect against paracetamol-induced liver damage; this may be due to the breakdown of the compound in the lysosomes after its release or to an unfavorable release pattern.

3164 CELL KINETIC STUDIES ON INTERFERENCE BETWEEN PROLIFERATIVE AND FUNCTIONAL METABOLISM IN REGENERATING RAT LIVER AFTER ADMINISTRATION OF PHENOBARBITAL.

(Ger.) Tuczek, H. V.; Skoruppa, W.; Rabes, H. M. (Pathologisches Institut der Universitat, D-8000 Munchen 2, Thalkirchnerstr. 36, W. Germany). *Virchows Arch. (Zellpathol.)* 17(4):347-361; 1975.

Studies were carried out in the regenerating livers of phenobarbital (PB)-treated rats to investigate the correlation between function and proliferation. Male adult Wistar rats received i.p. injections of 90 mg PB/kg daily for 5 days (group A). Rats in group B received additional injections of PB at a reduced dose (30 mg/kg) every 12 hr after partial hepatectomy, beginning immediately after the operation after a single injection of tritiated thymidine (^{3}H-TdR) at different intervals after surgery. The specific activity of DNA, ^{3}H-TdR labeling index, and mitotic index were determined 60 min after the ^{3}H-TdR injection. The intralobular distribution of DNA-synthesizing hepatocytes was analyzed in 22-hr regenerating liver. Stimulation of functional activities by PB resulted in a transitional synchronization of the start of DNA synthesis in liver parenchymal cells after partial hepatectomy. The labeling indices of group A and B increased to 36% and 30%, resp., as compared to 18.5% of NaCl-treated controls. Analysis of intralobular distribution of DNA-synthesizing hepatocytes revealed that higher levels of synchronization were limited to periportal zones of the liver lobule which provide optimal conditions for G_1-S transition. PB treatment apparently does not influence duration of S, G_2, or M under these conditions. The results stress the possibility that transitional synchronization of DNA synthesis by functional load might simulate stimulation of growth in a proliferating population.

3165 γ-GLUTAMYLTRANSPEPTIDASE IN THE RAT LIVER AFTER PORTACAVAL SHUNT.

(Eng.) Colombo, J. P.; Peheim, E.; Bachmann, C.; Muller, E.; Bircher, J. (Inselspital, 3010 Berne, Switzerland). *Pediatr. Res.* 10(1):18-24; 1976.

γ-Glutamyltranspeptidase (GGTP) activity was studied in livers of male SPF-Sprague-Dawley rats that were submitted to an end-to-side portacaval shunt (PCS) and in developing animals (15th gestational day to 15th postnatal day). To correlate the evolution of the enzymatic activity measured *in vitro*, histochemical techniques were used to localize enzyme activity in liver tissue. The GGTP activity in the adult rats was low (2.0 μmol/min/g). During fetal development, the enzyme activity rose beginning on the 15th gestational day from 630 ± 97 to 1,058 ± 20 μmol/min/g on the first postnatal day. The values declined and reached nearly adult values from the 10th postnatal day. After PCS, the GGTP activity exhibited a 3- to 6-fold increase (130 ± 69 to 371 ± 131 μmol/min/g) as compared with unoperated adult controls (53 ± 13 μmol/min/g). The highest levels corresponded to those observed between the third and fifth postnatal day in the developing rats. The histochemistry of GGTP in the fetal and newborn liver showed a regular distribution of the enzyme as a fine deposit in the hepatocytes throughout the whole tissue. Ten days after birth, the activity was low, at the same level as in the adult rat. In the period after PCS, hepatocytes began to show signs of enzymatic activity at the periphery of the hepatic lobules, which subsequently spread through the whole lobules. The increase of GGTP activity after PCS equaled the activity found in fetal animals. That correlated well in both groups with the reappearance of histologically demonstrable enzyme activity in hepatocytes. The increase of GGTP activity after PCS may be interpreted as a sign of functional changes leading to a reappearance of an enzyme normally present only in fetal and neonatal liver.

3166 THE EFFECT OF MASSIVE LIVER RESECTION ON PLATELET KINETICS IN THE RAT.

(Eng.) Siemensma, N. P.; Bathal, P. S.; Penington, D. G. (Dept. Medicine, Melbourne Univ., Fitzroy, 3065 Victoria, Australia). *J. Lab. Clin. Med.* 86(5):817-833; 1975.

The effect of partial hepatectomy on platelet kinetics was assessed in hooded Wistar rats. Four-fifths hepatectomy resulted in thrombocytopenia, reaching 50% of control platelet counts on the fifth postoperative day. Platelets accumulated in the sinusoids of the liver remnant after partial hepatectomy. During the first 2 postoperative days, 50% of platelets disappeared from the blood. After this, platelet numbers fell slowly for an additional 3 days, and was followed by recovery. Neither ^{51}chromium-labeled platelet survival nor total organ pooling of platelets varied from the normal after four-fifths hepatectomy. Although platelets accumulated in the liver remnant, the numbers involved did not contribute significantly to the thrombocytopenia. The mechanism responsible for the thrombocytopenia was suppression of entry of platelets into the peripheral blood. The observed effect was specific for platelets; erythropoiesis was not suppressed. Megakaryocytes showed a decrease in average diameter and ploidy value, a change seen also after physiologic suppression of platelet production; these findings suggest that the liver is concerned in the elaboration of thrombopoietin. However, as four-fifths hepatectomy results in immediate cessation of entry of platelets into the peripheral circulation, a phase of platelet production in which the principal physiologic regulator has been considered to have no effect, a second mechanism must be invoked, affecting the final step of platelet production.

3167 EFFECTS OF ROUTE OF ADMINISTRATION AND BLOOD FLOW ON HEPATIC DRUG ELIMINATION.

(Eng.) Shand, D. G.; Kornhauser, D. M.; Wilkinson, G. R. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *J. Pharmacol. Exp. Ther.* 195(3):424-432; 1975.

The effects of route of administration and blood flow on the elimination of lidocaine, diphenylhydantoin, and propranolol were investigated in the isolated perfused Sprague-Dawley rat liver. After administration directly into the portal vein, drug concentrations in the reservoir were the same at a given flow rate as concentrations in the hepatic vein after drug was placed directly into the reservoir. The apparent clearance of the drug, calculated from these concentrations, gave an estimate of intrinsic drug clearance, which is an estimate of the activity of the drug-metabolizing enzymes. Intrinsic clearance is defined as drug clearance when flow is not rate limiting and therefore should be independent of flow. This was confirmed by showing that, at steady state, neither hepatic venous drug concentrations nor concentrations in the reservoir after portal venous administration of lidocaine (58 μg/min) were affected by altering hepatic blood flow from 10 to 20 ml/min. Propranolol was given as a single 1-mg dose into the reservoir at flows of 10 and 20 ml/min. The area under the concentration-time curve (AUC) in the reservoir was decreased by increased flow, but AUC for hepatic venous blood was unchanged. Although AUC in hepatic venous blood was unchanged, higher peak concentrations and a more rapid half-life were seen. These data suggest that after p.o. drug administration, steady-state concentrations or AUC in systemic blood is dependent upon only the activity of the enzymes involved (i.e., intrinsic clearance) and is unaffected by flow, provided that the drug is completely absorbed and eliminated only by the liver. Furthermore, this applies even to drugs whose systemic clearance and drug half-life after i.v. administration is profoundly affected by altered hepatic blood flow.

SECRETION AND METABOLISM

Intestine

3218 EVIDENCE FOR BOTH LUMINAL AND SYSTEMIC FACTORS IN THE CONTROL OF RAT INTESTINAL EPITHELIAL REPLACEMENT. (Eng.) Clarke, R. M. (Univ. Hosp. Medical Sch., Nottingham NG7 2UH, England). *Clin. Sci. Mol. Med.* 50(2):139-144; 1976.

The effect of luminal and systemic factors on the control of intestinal epithelial replacement was investigated in male albino Wistar rats. One group of rats underwent the surgical isolation of a sac of upper small intestine, while in another group, a similar sac was created but a plastic infusion tube was implanted to admit fluid. Some rats were starved for 48 hr, while others were fed. The isolation of the sac did not significantly change villus height, crypt depth, or crypt/villus ratio in the fed animal, although it did cause a reduction in colchicine metaphase accumulation rate in the sac ($p<0.001$). Starving caused a further halving of cell production rate in the sac and a reduction in colchicine metaphase accumulation rate, both in the sac and in the terminal ileum of the intestine-in-continuity ($p<0.005$). Infusion of distilled water into isolated sacs for 72 hr caused a similar degree of stimulation of cell production in sacs, both in fed and starved rats. This confirms the importance of luminal factors in the regulation of epithelial cell production, as shown by the effects of isolation of a sac of intestine, and of infusion of distilled water. However, the reduction in cell production, which occurs when an animal bearing an isolated sac is starved, indicates that systemic factors cannot be ignored.

3219 DISACCHARIDASES IN RAT SMALL INTESTINAL MUCOSA FOLLOWING CYTOSTATIC TREATMENT WITH ADRIAMYCIN. (Eng.) Hartwich, G.; Domschke, W.; Matzkies, F.; Pesch, H.-J. (Med. Klinik u. Poliklinik, Universitat Erlangen-Nurnberg, D-8520 Erlangen, Krankenhausstrasse 12, Erlangen, W. Germany). *Res. Exp. Med.* 166(1):23-34; 1975.

The effects of cytostatic treatment with various i.p. doses of adriamycin on the disaccharidase activity of the small intestinal mucosa was investigated in SPF-Wistar rats. For each series of experiments, 60 rats received three i.p. shots of varying doses of adriamycin (1 x 3 mg/kg, 3 x 1 mg/kg at intervals of 24 hr, and 1 x 9 mg/kg). The rats manifested no macroscopic changes after doses of 1 x 3 mg/kg and 3 x 1 mg/kg. There was a marked reduction in vitality 48 hr following a 1 x 9 mg/kg dose, and 20 animals died within 120 hr. This dose also produced marked inflammatory changes in the intestine. There were marked histological changes at 24 hr in the nuclei and cytoplasm of the epithelia of the regenerative zone in the bottom of the crypts. At 3 days, many villi were transformed into swollen and flattened bumps in the mucosa. At 5-6 days, the villi regained their original slender profile. At 48 hr after administration of 1 x 9 mg/kg, all disaccharidase activities were reduced and after 72 hr, they were reduced by a statistically significant degree ($p<0.01$). After 24 hr, the sucrase and maltase activities in the jejunal mucosa manifested a slight insignificant elevation, and subsequently, they were clearly depressed. The lowest values were found after 72 and 96 hr. Following this, all the values increased again, but even after 7 days they had not re-attained their initial values. After low doses of adriamycin, the intestinal disaccharidase activities were depressed for a very long period of time. It appears that the reactivity-accelerated cell division, after cytostatic therapy, initially produces morphologically intact, but functionally immature, epithelia.

3220 DEMONSTRATION OF TWO DIFFERENT VITAMIN D-DEPENDENT CALCIUM-BINDING PROTEINS IN RAT INTESTINAL MUCOSA. (Eng.) Moriuchi, S.; Yamanouchi, T.; Hosoya, N. (Faculty Medicine, Tokyo Univ., 7-3-1, Hongo, Bunkyo-ku, Tokyo 113, Japan). *J. Nutr. Sci. Vitaminol. (Tokyo)* 21(4):251-259; 1975.

The characteristics and location of rat intestinal proteins with calcium binding properties were examined in female Wistar rats using both a ^{45}Ca-equilibrated Sephadex G-100 column and the chelex 100 method in the assay of ^{45}Ca binding activity. Cytosol from the small intestine mucosa of vitamin D-deficient rats was fractionated on a ^{45}Ca-equilibrated Sephadex G-100 column. Three ^{45}Ca binding peaks (BP) were formed. Peak I eluted at void volume. The elution volume (Ve) to void volume (Vo) ratio for peak II was 1.84 and for peak III, Ve/Vo=2.47. Peak I was identical with the ^{45}Ca binding peak obtained from vitamin D-deficient cytosol. The Ca binding activity was different in various parts of small intestine. Duodenal supernatants demonstrated a high activity in peak III area, while peak II activity was negligible. In the jejunum, peak II activity increased, while peak III decreased, so that their levels were almost equal. The ^{45}Ca binding activity of ileum was generally very low. Results obtained using the chelex 100 assay were different from those obtained by the Sephadex gel filtration method. The major difference was in peak II activity, which was found to be extremely low. These studies demonstrate the existence of at least three different Ca binding proteins and of a vitamin D-dependent Ca binding protein of molecular weight of 12,500 found mainly in the duodenum.

3221 MECHANISMS OF DISPOSAL OF ACID AND ALKALI IN RABBIT DUODENUM. (Eng.) Fiddian-Green, R. G.; Silen, W. (Harvard Medical Sch., Boston, MA 02215). *Am. J. Physiol.* 229(6):1641-1648; 1975.

Mechanisms by which the duodenal mucosa disposes of acid and alkali were studied in New Zealand rabbits. Stripped duodenal mucosa was mounted in Ussing chambers containing a Ringer solution gassed with 100% O_2. The disappearance of acid or alkali from the mucosal solution of short-circuited tissue was measured with a pH stat while the serosal pH was kept at 7.4. The duodenum rapidly disposed of both acid and alkali; neither property was altered by gassing with N_2 while iodoacetate was in the perfusing solutions. Prevention of release of CO_2 from the mucosal chamber obliterated the early rapid phase of acid disposal by the mucosa, while a similar maneuver in the serosal chamber increased the appearance of serosal acid without altering the rate of acid disposal. Gut sacs of duodenum *in vitro* and *in vivo* showed a positive correlation between acid disposal and the rate of luminal CO_2 production. While acid disposal progressively decreased with time for the *in vitro* gut sacs, the *in vivo* gut sac showed no fatigue in this respect. Luminal acidification in the Ussing chamber was associated with a profound reduction in short-circuit current, partially reversible by elevation of the mucosal pH but not by luminal glucose (5 mM). These data suggest that acid disposal occurs, in part, by intraluminal neutralization and, in part, by diffusion into the mucosa.

3222 NORMAL SERUM ALBUMIN TRANSFER FROM BLOOD TO SMALL INTESTINE AND ITS ROLE IN ALBUMIN BREAKDOWN. (Eng.) Herczeg, B. (1134 Budapest Robert Karoly krt. 82-84 Korhaz, Sebeszet, Hungary). *Acta Chir. Acad. Sci. Hung.* 16(1):13-25; 1975.

^{131}I-albumin transfer into isolated segments of the small intestine was determined following the i.v. injection of 100 μCi of human ^{131}I-albumin in 23 dogs. The importance of different intestinal segments in the normal degradation of albumin was established. The slope of the serum disappearance curve was unaltered, indicating that the applied technique had no damaging effect. Albumin leakage was not uniform in the whole length of the small intestine. It was highest in the duodenum (0.241 ml/10 cm intestine/hr). This was followed by the jejunum (0.142 ml/10 cm intestine/hr), and the smallest value was found in the ileum (0.082 ml/10 cm intestine/hr). The daily quantity of albumin leakage corresponded to a plasma volume of 14.49 ml in the duodenum, 27.16 ml in the jejunum, and to 23.76 ml in the ileum. The relation of albumin leakage and catabolism revealed that protein bound activity (transferred and regained) in the duodenum, in spite of this short section of the intestine, was responsible for 11.72 ± 1.70% of total catabolism, that in the jejunum for 21.28 ± 3.69%, and that in the ileum for 19.24 ± 3.64%. The sum of the catabolism of the three intestinal segments yielded 52.26 ± 6.65% of the total catabolism. After correction with a proteolytic factor, this value was 68.44%. These studies indicate that the small intestine is the main region of normal albumin breakdown.

3223 SEX VARIATION IN THE ACTIVITIES OF MUCOSAL HYDROLYTIC ENZYMES IN THE SMALL INTESTINE OF THE RAT. (Eng.) Hietanen, E. (Univ. Kuopio, P.O. Box 138, SF-70101 Kuopio 10, Finland). *Digestion* 13(1/2):33-41; 1975.

The mucosal response of alkaline phosphatase, ATPase, and disaccharidase (lactase, maltase, and trehalase) activities to sex hormones was studied by comparing male and female Wistar rats and castrated male rats. Castrated males were given testosterone propionate in propylene glycol (100 μl) i.p. every 48 hr for 10 days prior to sacrifice. Homogenates were prepared from mucosa scraped from three sections of the small intestine. Alkaline phosphatase showed a very steep gradient in the small intestine from the oral to the aboral end, while ATPase activity in the ileum was still about 50% of that in the duodenum. Both enzymes showed only minor sex variations and weak responses to castration. Lactase and maltase had peak activities in the jejunum, but trehalase activity was nearly equally as high in the duodenal mucosa as in the jejunum. In the jejunal mucosa, maltase activity was significantly ($p<0.05$) higher in male than in female rats. Castration did not markedly decrease activity, and a moderate increase followed testosterone administration. Lactase had much higher activity in the jejunum than in other sections. The female rats had only about 50% of the jejunal lactase activity found in males. The castration of males decreased activity ($p<0.01$) to the feminine pattern. Testosterone did not enhance it within 10 days. In the duodenal mucosa, the female rats had lower ($p<0.01$) activity than males, and also duodenal and jejunal activities ($p<0.05$) lower than males. Castration had no effect, but the administration of testosterone to castrated males significantly enhanced activity in the duodenum ($p<0.01$) and slightly in the jejunal mucosa. The data suggest marked species differences in adaptation of intestinal mucosa to environmental and hormonal factors.

3224 SUBSTRATE-INDUCED ACCELERATION OF LACTASE SYNTHESIS IN FETAL RAT INTESTINE.

(Eng.) Lifrak, I. L.; Lev, R.; Loud, A. V. (New York Medical Coll., Valhalla, NY). *Pediatr. Res.* 10(2):100-102; 1976.

Attempts were made to accelerate intestinal lactase synthesis in the fetal rat. Lactose (20 mg) was injected into the amniotic sacs of fetuses in one uterine horn, and 20 mg of glucose was injected into the amniotic sacs of fetuses in the opposite uterine horn of six rats on days 17 through 19 of pregnancy. Two or 3 days later, the pregnant animals were killed, and segments of jejunum, obtained from their fetuses, were homogenized in water and assayed for lactase. Lactase values were significantly higher ($p<0.005$) in the lactose-injected group than in fetuses receiving glucose. These values were 1.81 μM glucose/min/mg protein in fetuses injected with lactose, and 0.85 μM in the animals given glucose. Thus, fetal intestinal lactase activity can be increased by exposure to the substrate lactose during late fetal life.

3225 INTESTINAL METABOLISM OF GLUTAMINE AND GLUTAMATE FROM THE LUMEN AS COMPARED TO GLUTAMINE FROM BLOOD.

(Eng.) Windmueller, H. G.; Spaeth, A. E. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Insts. Health, Bethesda, MD 20014). *Arch. Biochem. Biophys.* 171(2):662-672; 1975.

An *in situ* preparation of rat jejunum was studied to determine metabolites produced from glutamine and glutamate absorbed in the intestine and to quantitate separately the metabolic rates of lumen-derived and blood-derived glutamine. Only a small fraction of the 6 mM L-[U-^{14}C]glutamate (2%) and the L-[U-^{14}C] glutamine (34%) administered into the lumen of Osborne-Mendel rat jejunal segments *in situ* was recovered unchanged in venous blood collected from the segments. The remaining ^{14}C of both amino acids was recovered in the blood as CO_2 (60%), proline (5%), citrulline (4%), alanine (3%), ornithine (2%), and organic acids, mostly lactate (19%). The amide nitrogen of glutamine was recovered mostly as ammonia and the amino nitrogen of both amino acids was predominantly alanine. A nearly identical distribution of products was seen in previously published experiments in which rat intestine took up L-[U-^{14}C]-glutamine from arterial blood. The results are therefore consistent with a single metabolic pool within mucosal cells for blood-derived and lumen-derived glutamine. When 6 mM glutamine was continuously perfused through the lumen, jejunal segments metabolized arterial and luminal glutamine at approximately equal rates [130-190 nmol min^{-1} (g of tissue)$^{-1}$]. The total combined rate was 1.7 times the rate of utilization of arterial glutamine alone in jejunal segments not absorbing glutamine. These results provide the first quantitative data on comparative metabolism by the intestine of substrates from the lumen and from blood. Rat intestine apparently metabolizes nearly all absorbed dietary glutamate and most glutamine in addition to circulating glutamine derived from other tissues.

3226 THE INFLUENCE OF INFUSIONS OF METHIONINE AND METHIONINE + GLUCOSE ON THE MORPHOLOGY AND FUNCTION OF SELF-EMPTYING JEJUNAL BLIND LOOPS IN THE RAT.

(Ger.) Menge, H.; Muller, K.; Lorenz-Meyer, H.; Riecken, E. O. (Medizinische Universitatsklinik, D-3550 Marburg a.d. Lahn, West Germany). *Virchows Arch. (Zellpathol.)* 18(2):135-143; 1975.

A study of the nutritive effect of an amino acid solution or a mixture of amino acid and sugar on the intestinal mucosa was investigated. Self-emptying blind loops of rat jejunum were perfused 3 times daily for 24 or 31 days with a Ringer solution or saline containing methionine and glucose or methionine alone. This was accomplished through a tube conveyed s.c. to the back of the neck. Methionine infusion induced a significant rise in the villus height of the mucosa of the blind loops; this was accompanied by an increased *in vivo* glucose absorption. In mucosal homogenates, there was a tendency toward an increase in dipeptidase activity but not in disaccharidase level. Infusion of a mixture of glucose and methionine led to lengthened crypts, as well as to larger villi. Glucose transport was again increased, and there was a small rise in both dipeptidase and disaccharidase activities.

3227 STUDIES ON THE BRUSH BORDER MEMBRANE OF MOUSE DUODENUM. II. MEMBRANE PROTEIN METABOLISM.

(Eng.) Billington, T.; Nayudu, P. R. V. (Dept. Zoology, Monash Univ., Clayton 3168, Victoria, Australia). *J. Membr. Biol.* 27(1/2):83-100; 1976.

The duodenal microvillus membrane protein metabolism of Swiss mice was measured using radioactive labeling techniques. Labeled amino acids [tritiated L-leucine (50 mCi/mM), ^{14}C-L-leucine (100-250 mCi/mM), ^{14}C-L-tyrosine, ^{14}C-DL-phenylalanine, and ^{14}C-L-valine (each 10 mCi/mM)] were introduced into the lumen of ligatured duodena. Following exposure to label, brush border membranes were isolated and analyzed. Experiments measuring the specific activity of protein labeled with a single amino acid revealed that total membrane protein appeared to turn over in about 14 hr. Protein in the mucosal homogenate had a turnover rate of about 8 hr. Turnover rates of individual proteins were measured with single and dual isotope experiments. Membrane protein was solubilized with sodium dodecyl sulphate (SDS) buffer. Single isotope experiments showed that all polypeptides separated on SDS-gels were maximally labeled at 6 hr after injection. Bands did not incorporate label linearly. Rates of loss (degradation) of label from membrane proteins in the 17 bands appeared to be related to the estimated molecular size of the proteins. Rates were highest for larger polypeptides. A double isotope technique, in which proteins were allowed to incorporate the same amino acid in two isotopic forms, delivered with a set time interval, revealed that the ratios of the second label to the first in the SDS-separated polypeptides were highest for larger proteins and lowest for smaller polypeptides. A mixture of labeled amino acids (excluding leucine) was used to show that differences in leucine contents of diferent proteins was not an explanation for the ariation in level of leucine radioactivity in ifferent bands. For specific activity measurements hroughout, protein in gels was quantitated with eference to the uptake of Coomassie stain. The use f this stain was validated by the finding that, t low protein concentration, the amount of stain aken up was proportional to the amount of bovine erum albumin or membrane protein loaded.

228 CALCIUM-BINDING ACTIVITY OF RAT INTESTINAL MUCOSA AFTER MASSIVE SMALL BOWEL RESEC-TION. (Eng.) Urban, E.; Jordan, J. W.; Pena, M.; erguson, K. A. (Univ. Texas Health Science Center, 703 Floyd Curl Drive, San Antonio, TX 78284). *Di-estion* 13(3):153-161; 1975.

he level of mucosal calcium binding activity in 50-m segments of duodenum, midgut, and ileum was investigated in male Sprague-Dawley rats 6-7 weeks after extensive proximal or distal small bowel resection or sham-operation. Initial and final body weights of sham operated and proximally and distally resected groups of animals did not differ significantly from the initial and final weights of a normal group ($p>0.05$). Sham-operation did not alter the calcium binding activity of midgut located on either side of the line of intestinal transection ($p<0.8$). Calcium binding activity increased significantly in duodenum ($p<0.001$) and midgut ($p<0.05$), but it did not change in ileum ($p<0.2$) in the animals receiving proximal resection. Binding activity remained greatest in the duodenum and decreased caudally in both the sham operated and normal groups of animals. In contrast to proximal resection, binding activity decreased significantly in duodenum (75%) in distally resected rats, but midgut and ileal binding activities were unchanged from sham operated animals. The results indicate that mucosal calcium binding activity also undergoes changes after massive intestinal resection and that the binding activity in the remaining gut varies with proximal or distal small bowel resection.

3229 PRIMATE PANETH CELL DEGENERATION FOLLOWING METHYLMERCURY HYDROXIDE INGESTION. (Eng.) Mottet, N. K.; Body, R. L. (Univ. Washington, Sch. Medicine, Seattle, WA 98195). *Am. J. Pathol.* 84(1): 93-110; 1976.

The ultrastructural effects of methylmercury on the intestinal epithelium were studied in 14 adolescent male *Macaca mulatta* monkeys weighing 3-5 kg. Two controls received daily an applesauce vehicle without methylmercury. Nine chronic low-dose animals received methylmercury at a dose of 0.2-1.0 mg/day for 80-491 days. Three acute high-dose animals received 2.0 mg methylmercury for 17-18 days, when they became terminally ill. Light and electron microscopic observations were made on postmortem samples of duodenum and ileum following perfusion and immersion fixation in a glutaraldehyde-paraformaldehyde fixative. Numerous uniquely structured inclusions were prominent in the Paneth cells of the chronic low-dose animals, and some necrotic Paneth cells were seen, especially in the animals receiving the higher doses and in those receiving methylmercury for a long time. Acute high-dose treatment produced some inclusions in the Paneth cells, which were similar to those of the chronic low-dose group, but degenerative and necrotic cells were observed more frequently. These alterations were not seen in other intestinal epithelial cells. It is concluded that Paneth cells are selectively altered and that Paneth cells may eliminate metals from the body.

3230 THE EFFECT OF HIGH TEMPERATURE ON THE ENZYMATIC ACTIVITY OF THE SMALL INTESTINE OF THYROIDECTOMIZED RATS. (Rus.) Rakhimov, K.; Korotina, N. A. (Dept. Physiology, Uzbek SSR Acad. Sciences, Tashkent, USSR). *Biull. Eksp. Biol. Med.* 80(9):31-33; 1975.

3231 FAT METABOLISM OF THE SMALL INTESTINE AND ITS RELATION TO THE LIPID AND LIPOPROTEIN METABOLISM OF THE ORGANISM. (Ger.) Gangl, A. (Ordinariat fur Gastroenterologie, Universitat Wien, Carnisongasse 13, A-1090 Vienna, Austria). *Acta Med. Austriacc (Suppl.)* 2(3):1-49; 1975.

GENERAL

3232 STUDY OF INDIRECT METHODS FOR MEASURING HEPATIC BLOOD FLOW IN THE ISOLATED PERFUSED DOG LIVER. (Eng.) Groszmann, R. J.; Dubin, M.; Royer, M. (Veterans Admin. Hosp., West Spring St., West Haven, CT 06516). *Digestion* 13(4):220-231; 1975.

The reliability of the constant infusion clearance and extraction technique (CIT) and the single injection clearance method (SIT) for measuring hepatic perfusate flow at different levels of liver function was assessed. In 36 isolated perfused dog livers, hepatic perfusate flow (HPF) was monitored by a direct method (DM), and the HPF was simultaneously measured with an indirect method (IM) utilizing BSP as indicator (20 SIT and 16 CIT). In 16 experiments, absolute 750 mM ethanol and 600 μM sodium taurocholate were separately utilized to impair BSP metabolism. By comparison with DM, in the experiments with an extraction ratio (ER) of BSP lower than 10%, the error of the IM was 154.57 ± 46.55 ml/min for the CIT and 107.25 ± 34.20 ml/min for the SIT. This error was significantly greater than in the experiments with an ER greater than 10% (CIT 15.70 ± 3.88 ml/min, SIT 8.20 ± 1.38, $p<0.01$). In the studies with ER less than 10%, no difference was found in the error detected with the SIT (107 ± 34.20 ml/min) and CIT (154.37 ± 46.55 ml/min) measurements; in the experiments with an ER greater than 10%, the error with the CIT (15.70 ± 3.88 ml/min) was greater than the one attained with the SIT (8.20 ± 1.38 ml/min, $p<0.10>0.05$). It is concluded that both methods are reliable techniques for measuring HPF in livers with normal or near normal clearance capacity, but even in these ideal experimental conditions, the values for HPF are inaccurate when the liver clearance function is moderate or severely impaired.

3233 ISOLATION, COMPOSITION AND REACTIVITY OF THE NEUTRAL GLYCOPROTEINS FROM HUMAN MECONIUMS WITH SPECIFICITIES OF THE ABO AND LEWIS SYSTEM.

(Eng.) Cote, R. H.; Valet, J. P. (Universite Laval, Dept. Biochimie, Quebec, Quebec, G1K 7P4, Canada). *Biochem. J.* 153(1):63-73; 1976.

The chemical and immunological properties of blood group specific A$_1$, B, AB, H and Le^a neutral glycoproteins were studied. They were isolated from suitable pools of human normal meconiums by a preliminary fractionation with a cationic detergent at pH 5 and 9 (borate), followed by ion exchange and gel chromatography. Out of more than 500 meconiums tested, 19% were inactive to the ABH system. The ABH materials had sedimentation coefficients of 10S-11S, while the Le^a preparation, not strictly homogeneous, showed a coefficient of 7S. The glycoproteins all possessed a common peptide core, but they differed from one another with respect to their fructose, galactose, and hexosamine content. There were stable ratios of N-acetylglucosamine/galactose (4:3) in the B, H and Le^a materials and of N-acetylglucosamine/galactose (24:39) in the A, H, and Le^a materials, from which the numbers of A and B determinants were estimated. In the ABH substances, the ratio of glucosamine to the sum of threonine and serine was stable. Presumably because of genetic factors, the amount of fucose varied among the different glycoproteins, but it was always definitively lower than that in the average cyst substances. Various serological tests and precipitin methods were used to measure the potency, purity, and integrity of the preparations, including comparisons between A$_1$ and A$_2$ substances from this source. The Le^b activity did not appear to be as high as it is in glycoproteins from adults; this may have been a possible interpretation due to the immature Lewis system as observed on erythrocytes and it may explain their very strong inhibiting power to iso-agglutinins. It is concluded that the family of neutral glycoproteins isolated from human meconiums clearly differs in some aspects from the corresponding ones in cyst fluids. It is suggested that this is due to the source itself, and to the evolution of the integrated Lewis system.

3234 RABBIT GUT-ASSOCIATED LYMPHOID TISSUE: MAJOR PATHWAY FOR THORACIC DUCT LYMPHOCYTE CIRCULATION.

(Eng.) Perey, D. Y. E.; Milne, R. W. (McMaster Univ. Medical Center, Hamilton, Ontario, Canada). *Lab. Invest.* 33(6):678-686; 1975.

Cytokinetic studies were conducted in rabbits to characterize the distribution of both uridine- and thymidine-labeled thoracic duct lymphocytes (TDL) in various lymphoid tissues. Rabbits received i.v. injections of 8-11 x 10^8 autologous or allogeneic TDL 95% of which had incorporated ^{3}H-uridine during a 1-hr *in vitro* incubation. Autoradiographs of tissues collected 24 hr after injection of TDL failed to demonstrate any trapping of label in liver or *in vivo* reutilization of ^{3}H-uridine. No differences in the distribution of labeled cells were noted between recipients of autologous and allogeneic TDL. The paracortical areas of lymph nodes and periarterial areas of splenic follicles contained many heavily labeled cells; these areas therefore appear to correspond to thymus-dependent areas, as in other rodents. The tonsils contained densely packed sheets of labeled cells. In the tonsillar, but not in other germinal centers, evenly distributed, lightly labeled cells were seen. Small clusters of heavily labeled cells were seen in the bronchus-associated lymphoid tissue. In the gut-associated lymphoid tissue (GALT) such as the appendix, sacculus rotundus, and Peyer's patches, densely packed and heavily labeled cells were seen in the interfollicular areas; fewer heavily labeled cells were scattered throughout the dome and corona of GALT. In the dome and corona, however, there were many lightly labeled cells. The germinal centers of GALT were lacking totally in uridine-labeled cells. Some 20% of TDL collected 24 hr after injection of uridine-labeled TDL were labeled, thereby reflecting considerable recirculation of TDL. Thymidine-labeled immunoblasts (24-48 x 10^6), obtained from the TDL incubated with ^{3}H-thymidine *in vitro*, and injected into autologous or allogeneic recipients, which were killed 24 hr later, revealed heavily labeled cells in the intestinal lamina propria, the dome, corona, and interfollicular areas of GALT, as well as throughout the spleen, lymph nodes, and tonsils. There was a two to threefold higher concentration of labeled cells in the appendiceal and mesenteric lymph nodes than in respective popliteal nodes. It is concluded that rabbit GALT contains a substantial number of cells belonging to the pool of recirculating lymphocytes and that B and T cells in the thoracic duct may have different rates of uridine incorporation, as has been shown in other rodents.

3235 ENTERIC MIGRATION OF RADIOLABELED LYMPHOCYTES.

(Eng.) Solomon, G. E.; Taub, R. N. (Mt. Sinai Sch. Medicine, New York, NY 10029). *Cell. Immunol.* 23(1):108-116; 1976.

The migratory patterns of circulating radio-isotopically labeled lymphocytes were studied in mice by means of serial transfer into syngeneic recipients. Mice were injected with lymphocytes labeled with 5-iodo-2-deoxyuridine-^{125}I (IUDR) or sodium chromate-^{51}Cr. These lymphocytes were obtained from various lymph nodes, thymus, spleen, and

Peyer's patches. The radioactivities present in various enteric and non-enteric tissues of recipient mice were measured for up to 24 hr. The patterns of distribution of the two labels were very different. The labels were equally distributed amongst the non-enteric tissues; however, IUDR showed a marked accumulation in gut tissues. Only 1% of the total recovered ^{51}Cr was present in the gut after 2 hr; however, the amount of IUDR in gut increased from 2 to 24 hr, with approximately 41% of the label present in the gut at the end of the experiment. It is concluded that lymphocytes from all origins display this preference and that there is no species difference in migration patterns of the labels. It is suggested that the IUDR specific lymphocytes are a lymphocyte subpopulation, and that immature thymocytes possess migrational specificity and may leave the adult thymus and colonize gastrointestinal tissue.

3236 DEGRADATION OF BLOOD GROUP ANTIGENS IN HUMAN COLON ECOSYSTEMS. I. IN VITRO PRODUCTION OF ABH BLOOD GROUP-DEGRADING ENZYMES BY ENTERIC BACTERIA. (Eng.) Hoskins, L. C.; Boulding, E. T. (Veterans Admin. Hosp., Cleveland, OH 44106). *J. Clin. Invest.* 57(1):63-73; 1976.

The production of blood group degrading (BGD) enzymes in fecal cultures was investigated to determine whether the cultures are a source for enzyme purification and how blood group antigen degrading enzymes are adapted in individual human colon ecosystems. BGD enzymes were present in fecal cultures from 27 healthy subjects, including ABH nonsecretors. Heat sensitive obligate anaerobes were their major source. From 39 to 85% of the total enzyme activity produced by growing cultures was extracellular. Commercial hog gastric mucin (2 mg/ml) and salivary glycoproteins, including Le^a saliva which lacks A B, and H antigens, enhanced production of A-, B-, and H-degrading activity in anaerobic fecal cultures, irrespective of the glycoprotein's blood group specificity. The host's ABO blood type and secretor status affected the specificity of BGD enzymes produced by fecal bacteria *in vitro*. Fecal inocula from B secretors incubated with hog gastric mucin (A and H specificity), or with Le^a saliva, produced a 2- to 20-fold greater levels of B-degrading than A- or H-degrading activity and inocula from A secretors, in similar media, produced greater levels of A-degrading than B- or H-degrading activity. BGD enzymes produced in fecal cultures were glycosidases and not proteases. The B-degrading enzyme cleaves the B antigenic determinant α-D-galactose from the oligosaccharide side chains of mucin glycoproteins with B specificity. It is concluded that anaerobic fecal cultures containing blood group substances are a feasible source for purifying blood group antigen degrading enzymes.

3237 INDUCTION OF UNDIFFERENTIATED ADENOCARCINOMA IN THE STOMACH OF RATS BY N-METHYL-N'-NITRO-N-NITROSOGUANIDINE WITH VARIOUS KINDS OF SURFACTANT. (Eng.) Takahasi, M; Fukushima, S.; Hananouchi, M. (Nagoya City Univ. Med. Sch., Kawasumi 1, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan). *Gann* 17:255-267; 1975.

The carcinogenic effect of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) combined with four kinds of surfactant--polyoxyethylene sorbitan monostearate, polyoxyethylene nonylphenyl ether, and two types of alkylbenzenesulfonate--was investigated in male Wistar rats. The rats were divided into four groups and were administered either 100 mg/l MNNG containing 0.4% Tween 60 (group I), 100 mg/l MNNG containing 0.2% Nonipol (group II), 100 mg/l MNNG containing 0.1% hard type alkylbenzenesulfonate (group III), or 100 mg/l MNNG containing 0.1% soft type alkylbenzenesulfonate (group IV). Upon termination of the experiment, all rats that died or were killed were autopsied. The findings showed that the incidence of adenocarcinomas in the glandular stomach was 40-80% in all groups. The tumors formed polypoid nodules or ulcerative umbilicated nodules with elevated borders. Some infiltrated widely into the stomach wall and invaded the serosa. Undifferentiated adenocarcinomas were observed in 4 of 10 adenocarcinomas in group I, in 3 of 12 in group II, in 2 of 9 in group III, and in 2 of 4 in group IV. In contrast to the well differentiated tumors, the undifferentiated types were characterized by loss of glandular arrangement. The anaplastic tumor cells showed polymorphism, increased basophilia of the cytoplasm, and hyperchromatism of the nucleus. Electron microscopic examination revealed two types of signet ring cells: one type was closely packed with mucin, pushing the nucleus to one side and resembling a signet ring; the other type had a small cystic luminal structure in the cytoplasm, its wall lined with microvilli projecting into the lumen. It is concluded that the four groups exhibited prominent carcinogenesis as compared with the control group, and that undifferentiated adenocarcinoma of the experimental cancer resembles that of human gastric cancer.

3238 DUODENOGASTRIC REFLUX OF LYSOLECITHIN IN THE PATHOGENESIS OF EXPERIMENTAL PORCINE STRESS ULCERATION. (Eng.) Kivilaakso, E.; Ehnholm, C.; Kalima, T. V.; Lempinen, M. (Second Dept. Surgery, Univ. Helsinki, Haartmaninkatu 4, 00290 Helsinki 29, Finland). *Surgery* 79(1):65-69; 1976.

The role of duodenogastric reflux of lysolecithin in the pathogenesis of gastric stress ulcerations was investigated with a swine shock-ulcer model in 27 piglets weighing 8-12 kg. In an intact animal, the average concentration of intragastric lysolecithin before shock was 138 μg/ml. At the end of the shock period, the average concentration of lysolecithin was 540 μg/ml, and the overall amount in the gastric juice was 14.3 mg. Following hemorrhagic shock (3 hr duration; mean arterial pressure, 40 mm Hg), all six control animals with normal gastroduodenal continuity developed gastric ulcerations. Interruption of duodenogastric reflux by duodenal exclusion and gastrojejunostomy completely abolished the development of these ulcerations in six test animals. When the interrupted duodenogastric reflux was replaced artificially by intragastric instillation of lysolecithin (500 μg/ml, 25 ml), all six animals developed lesions. Intragastric lysolecithin without shock had no effect. The results support the concept that regurgitation of duodenal juice into the stomach is an essential factor in the pathogenesis of gastric stress ulceration and suggests that lysolecithin is one of the active components in duodenal juice.

3239 MICROVASCULAR CONTROL IN INTESTINAL MUCOSA OF NORMAL AND HEMORRHAGED RATS. (Eng.)

Bohlen, H. G.; Hutchins, P. M.; Rapela, C. E.; Green, H. D. (Wake Forest Univ., Bowman Gray Sch. Medicine, Winston-Salem, NC 27101). *Am. J. Physiol.* 229(5):1159-1164; 1975.

The mucosal microcirculation in innervated and denervated small intestine was investigated in anesthetized male Wistar rats. Denervation did not cause significant ($p>0.05$) diameter changes in the precapillary vasculature; however, venules did constrict significantly ($p<0.05$). Denervating a short loop of small intestine did not change the overall systemic cardiovascular response of the animals during and following hemorrhage. The control diameters of the innervated and denervated arterioles were not significantly different ($p>0.05$). The denervated vessels dilated significantly ($p<0.05$) and the innervated vessels constricted significantly ($p<0.05$) during the hemorrhage period. The innervated precapillary sphincters constricted significantly ($p<0.05$) and the denervated vessels dilated significantly ($p<0.05$) during the hemorrhage period. The innervated venules, which did not respond during the carotid occlusion, constricted significantly ($p<0.05$) during the hemorrhage period. In contrast, the denervated second order venules dilated significantly ($p<0.05$) during the hemorrhage period. The denervated collecting venules dilated significantly ($p<0.05$) during the first half of the hemorrhage period and constricted to their control diameter during the latter half of the hemorrhage period. The vasoconstriction of the innervated vasculature during hemorrhage contributed to a stoppage of blood and epithelial detachment; these responses did not occur in the dilated, denervated vasculature. It is concluded that neutral vasoconstriction, qualitatively similar to that in normal animals during the baroreceptor reflex, contributes to the vascular and tissue impairment in the intestinal mucosa during hemorrhage.

3240 THE EFFECTS OF CALCIUM AND MAGNESIUM ON INHIBITORY JUNCTIONAL TRANSMISSION IN SMOOTH MUSCLE OF GUINEA PIG SMALL INTESTINE. (Eng.)

Holman, M. E.; Weinrich, J. P. (Dept. Physiology, Monash Univ., Clayton, Victoria 3168, Australia). *Pfluegers Arch.* 360(2):109-119; 1975.

The effects of calcium and magnesium on inhibitory junctional transmission in smooth muscle of guinea pig small intestine was investigated using intracellular electrodes. Transmural stimulation in the presence of atropine (3×10^{-7} g/ml) caused a transient hyperpolarization and inhibitory junction potential (IJP). Both divalent cation concentrations affected the amplitudes of IJP's. When either the Mg concentration was increased (1-20 mM) or the Ca concentration was decreased (2.5-0.25 mM), there was a marked decrease in the amplitude of the IJP. At 0.25 mM Ca^{2+}, the IJP amplitude was reduced to about 20% of its normal value. Increased Mg^{2+} depressed the amplitude of the IJP's, so that a much larger Ca^{2+} concentration was required to produce IJP's with amplitudes comparable to those obtained with 1 mM Mg^{2+}. With 10 mM Mg^{2+} and 0.25 mM Ca^{2+}, the IJP was abolished. The IJP amplitude decreased to about 30% of its original value, with a 20-fold increase in Mg^{2+}. However, while reducing Ca^{2+} by one half reduced the IJP amplitude, increasing Mg^{2+} had no effect until 10 times the normal concentration was reached. Indirect evidence is presented suggesting that the decrease in amplitude of the IJP is due to a decrease in the amount of transmitter released. The results indicate that the size of the IJP is a function of the concentration of the Ca and Mg ions. It appears that the release of transmitter from these nerves utilizes the same mechanism as other nerve endings.

3241 THE ENTEROGLUCAGON RESPONSE TO INTRAJEJUNAL INFUSION OF GLUCOSE, TRIGLYCERIDES, AND SODIUM CHLORIDE, AND ITS RELATION TO JEJUNAL INHIBITION OF GASTRIC ACID SECRETION IN MAN. (Eng.)

Holst, J. J.; Christiansen, J.; Kuhl, C. (Bispebjerg Hosp., DK-2400, Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 11(3):297-304; 1976.

The enteroglucagon response to intrajejunal infusion of glucose, triglycerides, and sodium chloride, and its relation to jejunal inhibition of gastric acid secretion was investigated in four volunteers. Venous blood samples were obtained before and 15 min after a continuous infusion of 0.5 µg/kg/hr pentagastrin over 3 hr. After 90 min of infusion, 100 ml of 50% glucose, 100 ml 9.3% NaCl, or 100 ml 20% triglyceride emulsion was infused over 5 min into the jejunum. A plateau of gastric acid secretion was reached after 45 min of infusion. Total glucagon was significantly depressed during hyperglycemia and reached significance at 3 hr ($p<0.05$). The glucose infusion led to a more than fivefold increase in total glucagon concentration in each subject ($p<0.025$). Concentration of pancreatic glucagon was not significantly changed, but the insulin increase was significant at 120, 135, and 150 min ($p<0.01$, $p<0.025$ and $p<0.05$, resp.). The infusion of triglyceride emulsion elicited a marked total glucagon response ($p<0.05$ at 120-150 min, $p<0.025$ at 165 and 180 min). There was an increase in the concentration of pancreatic glucagon ($p<0.05$) at 135 and 150 min, while the insulin and glucose values were unchanged. The infusion of NaCl led to a late and modest rise in total glucagon concentration ($p<0.05$ at 165 min), while insulin pancreatic glucagon, and glucose were unchanged. In almost all cases, the pentagastrin infusion led to a small increase in insulin concentrations after 15 min of infusion ($p<0.01$). It is concluded that enteroglucagon is not responsible for the jejunal inhibition of gastric acid secretion by jejunal administration of hyperosmolol NaCl solution, but it may participate in the inhibition evoked by jejunal administration of glucose or triglycerides.

3242 PROTECTION OF THE INTESTINAL MUCOSA DURING ISCHAEMIA BY INTRALUMINAL PERFUSION. (Eng.)

Mirkovitch, V.; Menge, H.; Robinson, J. W.

L. (Departement de Chirurgie Experimentale, Hopital Cantonal Universitaire, Lausanne, Switzerland). *Res. Exp. Med. (Berl.)* 166(2):183-191; 1975.

The function of the intestinal mucosa following 1 hr of ischemia was examined in mongrel dogs *in vivo* and *in vitro*. During ischemia, the intestinal loop was perfused with media of different composition to determine which provided the best protection for the epithelium. The absorption of water, ions, and glucose was then monitored *in vivo*, and the uptake of 1 mM phenylalanine and 1 mM β-methyl-D-glucoside by slices of mucosa was determined *in vitro*. The unprotected mucosa lost all active transport capacity *in vitro* following 1 hr of ischemia, and it was the site of a pronounced loss of water and ions into the lumen *in vivo*. *In vivo* glucose absorption was also abolished. If the loop was perfused with 0.2% glucose containing Krebs bicarbonate buffer, much of the *in vitro* transport capacity was retained. The loss of ions and water was prevented, and *in vivo* glucose absorption occurred. Perfusion with other media, such as isotonic mannitol (300 mOsm/l), Krebs bicarbonate buffer (285 mOsm/l), or Ringer-lactate solution (295 mOsm/l) resulted in a marked protection of the mucosa in comparison with the unperfused loop, but the effects were not as pronounced as those of the glucose containing buffer. It is concluded that the act of perfusing the intestine is the most important protective factor but that the presence of glucose in the perfusate does increase protection.

3243 INCREASED CYCLIC ADENOSINE 3',5'-MONOPHOSPHATE CONTENT IN GUINEA PIG ILEUM AFTER EXPOSURE TO Staphylococcus aureus DELTA-TOXIN.

(Eng.) O'Brien, A. D.; Kapral, F. A. (Dept. Medical Microbiology, Ohio State Univ., Columbus, OH 43210). *Infect. Immun.* 13(1):152-162; 1976.

The effect of delta-toxin on the cyclic AMP (cAMP) content of guinea pig ileum maintained *in vitro* was studied to compare *Staphylococcus aureus* delta-toxin with cholera toxin, which is known to increase cellular cAMP. Concentrations of delta-toxin as low as 0.40 μg/ml increased cAMP levels in guinea pig ileum after 2 hr of incubation at 37 C. Histological damage was seen in ileum exposed for 2 hr to 100 μg/ml of delta-toxin. As little as 3 μg of delta-toxin increased vascular permeability in guinea pig skin. Permeability changes became evident within 5 min and were maximal within 6 hr, whereas those produced by cholera toxin required 24 hr to become maximal. Benadryl (50 mg/kg, i.p.) did not interfere with the ability of these toxins to alter vascular permeability. Purified egg lecithin reduced the effectiveness of delta-toxin in the skin but it did not inhibit cholera toxin. Delta-toxin in concentrations as low as 0.1 μg/ml caused dislodgement of HeLa cells in tissue cultures. Therefore, delta-toxin appears unique in being the only bacterial toxin, currently known to alter water absorption in the ileum, that is capable of both increasing cAMP levels and being cytotoxic. These findings suggest a possible role for delta-toxin in the pathogenesis of staphylococcal enteritis.

3244 MULTIPLE FORMS OF HUMAN GLUTATHIONE S-TRANSFERASE AND THEIR AFFINITY FOR BILIRUBIN.

(Eng.) Kamisaka, K.; Habig, W. H.; Ketley, J. N.; Arias, I. M.; Jakoby, W. B. (National Insts. Health, Bethesda, MD 20014). *Eur. J. Biochem.* 60(1):153-161; 1975.

Several species of glutathione-S-transferase, designated as transferases alpha, beta, gamma, delta, and epsilon on the basis of increasing isoelectric points, were isolated from human liver. Molecular weight of the transferases was estimated by gel filtration on standardized columns of Sephadex G-100, yielding a value between 48,000 and 49,000.
Each transferase had a similar specific activity for a given electrophilic substrate; this was highlighted by the K_m values for 1-chloro-2,4-dinitrobenzene with transferases alpha, beta, gamma, delta, and epsilon (0.45, 0.40, 0.51, 0.63, and 0.43 mM, resp.) and the V values (940, 1300, 1205, 2910, and 2340 mol/min/mol/protein, resp.). These values are in marked contrast to rat glutathione transferases; the sepcific activity for a given substrate may differ by a factor of a thousand or more. Differences in dissociation constants, D_d, for bilirubin among the transferases varied by 10-fold although each enzyme species was able to bind bilirubin. The K_d for bilirubin was estimated as 65, 110, 34, 18, and 34 μM for transferases alpha, beta, gamma, delta, and epsilon, resp. Transferases alpha and delta bound indocyanine green with a K_d of about 20 μM for each enzyme and bound hematin with a K_d of 10 μM. The results indicate that there is a close resemblance among the human proteins; this is reflected in the reaction of each with a monospecific antibody, the identical spectrum of substrates, and the minor differences observed in kinetic constants.

3245 SUSCEPTIBILITY OF THE LIVER AND BILIARY TRACT TO ANAEROBIC INFECTION IN EXTRAHEPATIC BILIARY TRACT OBSTRUCTION: BACTERIOLOGICAL INVESTIGATIONS--AN EXPERIMENTAL STUDY IN RABBITS.

(Eng.) Nielsen, M. L.; Justesen, T. (31 Sofievej, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 10(7):769-775; 1975.

The influence of common duct occlusion on susceptibility to infection with anaerobic gram-negative rods was investigated in 18 New Zealand White rabbits in which ligation of the common duct was performed. Three *Bacillus fragilis* strains isolated from human infections and a stock culture of *Fusobacterium mortiferum* (1.9 x 10^9, 2.0 x 10^9, and 0.9 x 10^9 organisms for *B. fragilis* I, II, and III, resp.; 1.2 x 10^9 organisms for *F. mortiferum*) were injected i.v. Liver tissue, gallbladder, bile, and blood were investigated. Anaerobic culture procedures were based on the use of a "glove-box" with an oxygen-free atmosphere and prereduced, anaerobically sterilized media. Anaerobic transport was based on flushing of samples with oxygen-free carbon dioxide and transport-time of less than 30 min. Common duct occlusion significantly increased the number of infected animals inoculated with *F. mortiferum* and with the first two *B. fragilis* strains as compared to a control group of 18 inoculated animals without common duct occlusion. Spontaneous infection did not arise in a control group of animals with common duct ligation. It is concluded that in biliary tract occlusion, anaerobic bacteria are able to invade the biliary tract from the blood stream, and that biliary tract occlusion produces sufficient anaerobic conditions for obligate anaerobic bacteria to multiply in the bile.

3246 ACTION OF INTRAGASTRIC ETHANOL ON THE PANCREATIC SECRETION OF CONSCIOUS RATS. (Eng.) Cavarzan, A.; Teixeira, A. S.; Sarles, H.; Palasciano, G.; Tiscornia, O. (Inserm U 31, 46, Chemin de la Gaye, F-13009 Marseille, France). *Digestion* 13(3):145-152; 1975.

The pancreatic response to intragastric alcohol and intraduodenal hydrochloric acid was investigated in conscious male Wistar rats. Rats were given either 20% alcohol (A) or water (W) daily for 13 months. In A rats, the intragastric injection of 2 g/kg 20% ethanol significantly increased the pancreatic secretion of protein ($p<0.05$), and to a lesser extent, of water. In control rats, the response was biphasic. In the first 30 min, flow rate and protein output were significantly increased, while in the second hour, flow rate, protein, and bicarbonate outputs were significantly ($p<0.05$) lower than in the basal period. Intraduodenal injection of HCl increased the flow rate in both groups, but the protein output was only increased in the W group. Bicarbonate concentration and output were not significantly modified. Since the action of intraduodenal HCl in alcoholics and in controls is not different, it is probable that the release of secretin is not greatly modified in cases of chronic alcoholism.

3247 ACUTE HEMORRHAGIC PANCREATIC NECROSIS IN MICE: INFLUENCE OF THE AGE AND SEX OF THE ANIMALS AND OF DIETARY ETHIONINE, CHOLINE, METHIONINE, AND ADENINE SULFATE. (Eng.) Lombardi, B.; Rao, N. K. (Dept. Pathology, Univ. Pittsburgh, Pittsburgh, PA 15261). *Am. J. Pathol.* 81(1):87-100; 1975.

Factors influencing the development of acute hemorrhagic pancreatitis (pancreatic necrosis, AHPN), with fat necrosis were investigated in Swiss-Webster mice fed DL-ethionine with a choline-deficient diet. In mice fed a choline-deficient diet containing 0.5% ethionine, the incidence of AHPN with fat necrosis was 100% in young female mice (30 days old), 65% in adult females (70 days old), 70% in young males, and only 41% in adult males. All young female mice died within 5 days, while some of the adult mice and young males, which developed AHPN died on the sixth or seventh day of treatment. The incidence of hemorrhagic pancreas and fat necrosis increased with increasing amounts of ethionine in the diet. It was 10, 80, and 100% in young mice when the ethionine level was 0.10, 0.25, and 0.35%, resp. A majority of young mice fed 0.10% ethionine survived for at least 29 days. Of those fed 0.35% ethionine, all died within 4-10 days. The incidence was only 10-20% when 0.5% ethionine was fed with either a choline-supplemented diet or with laboratory chow. The development of pancreatic pathology was completely prevented by including in the diet 0.5% methionine, but not 0.5% adenine. The results indicate that ethionine administration can induce a variety of lesions in the pancreas of mice, depending upon the experimental conditions employed and the length of the treatment.

3248 EVALUATION OF [^{14}C]AMINOPYRINE CLEARANCE FOR DETERMINATION OF GASTRIC MUCOSAL BLOOD FLOW. (Eng.) Tague, L. L.; Jacobson, E. D. (Univ. Texas Medical Sch. Houston, Houston, TX 77025). *Proc. Soc. Exp. Biol. Med.* 151(4):707-710; 1976.

Studies to reduce the assay time and to evaluate the low concentrations of ^{14}C-labeled aminopyrine for determining gastric mucosal blood flow were performed in both anesthetized dogs and in conscious dogs with a gastric fistula and a Heidenhain pouch. A bolus of 3 μCi of ^{14}C-aminopyrine was injected intravenously in 168 ml saline. Then, a continuous infusion was started at a rate of 0.0125 μCi/min. Clearance was measured by both radiometric and spectrophotometric methods. There was a high correlation between the radiometric and spectrophotometric determinations; the radiometric method was easier, safer, and it allowed a larger number of samples to be determined. No significant differences were found between mucosal blood flows estimated simultaneously by ^{14}C-aminopyrine clearance and by unlabeled aminopyrine in anesthetized dogs during manipulation of the flows with 1.2 μg/kg/min histamine and 10 U/hr vasopressin, demonstrating that the labeled base may be used alone, without protection against metabolic degradation afforded by unlabeled aminopyrine. In the conscious dog with Heidenhain pouch, disappearance of residual ^{14}C label was complete within 36 hr. The clearance of small amounts of ^{14}C-aminopyrine was unaffected by injection of an unlabeled bolus containing 2,000 times more absolute aminopyrine than the total labeled dose, showing that mucosal extraction is not concentration-limited. It is suggested that small amounts of labeled aminopyrine may provide an excellent tool for examining the role of mucosal blood flow in the pathogenesis of gastric disease in man.

3249 PROLONGED INTESTINAL ASSISTANCE IN THE DOG. (Fre.) Joyeux, H.; Astruc, B.; Martin, P.; Yakoun, M.; Lafont, J.; Solassol, Cl. (Laboratoire de Biochimie des proteines, Faculte des Sciences, 34000 Montpellier, France). *Ann. Chir.* 28(9):795-802; 1974.

3250 CHANGES IN THE CONTENT OF ACETYLCHOLINE IN THE WALL OF THE STOMACH IN FORMATION OF "STRESS" AND "STEROID" ULCERS OF THE STOMACH IN THE ANIMALS WITH DISTURBED FUNCTION OF THE THYROID. (Rus.) Rosolovskii, A. P. (Ternopol Medical Inst., Ternopol, USSR). *Patol. Fiziol. Eksp. Ter.* (4):44-48; 1975.

3251 STUDY OF CERTAIN FACTORS IN THE COLONIZATION OF THE DIGESTIVE TUBE OF THE WHITE MOUSE BY Candida Albicans. (Fre.) Auger, P.; Joly, J. (Dept. Microbiology and Immunology, Univ. Montreal, Montreal, Quebec H3G 3J7, Canada). *Can. J. Microbiol.* 22(3):334-337; 1976.

3252 ARTERIAL ANATOMY OF THE COLON. (Fre.) Lamarque, J. L.; Bruel, J. M.; Senac, J. P.; Boulet, P.; Alonzo, R. (Cliniques Saint-Eloi, F 34059 Montpellier Cedex, France). *Ann. Radiol. (Paris)* 19(3):315-316; 1976.

3253 RADIOLOGICAL ANATOMY OF THE HEPATIC ARTERY. (Fre.) Lamarque, J. L.; Senac, J. P.; Bruel, J. M.; Gau, A.; Toulza, A. (Cliniques Saint-Eloi, F 34059 Montpellier Cedex, France). *Ann. Radiol. (Paris)* 19(3):316-318; 1976.

3254 THE DEVELOPMENT OF BACTERIAL FLORA IN THE GASTROINTESTINAL TRACT OF THE MONGOLIAN GERBIL. (Eng.) Majumdar, S. K.; Mosher, R. H. (Dept. Biology, Lafayette Coll., Easton, PA 18042). *Proc. Pa. Acad. Sci.* 48:139-141; 1974.

3255 INTERACTION OF ANTIBODIES WITH CHOLERA ENTEROTOXIN IN RAT SMALL INTESTINE: AN IN VTIRO STUDY [Abstract]. (Eng.) Wu, A.-L.; Walker, W. A. (Massachusetts General Hosp., Boston, MA). *J. Cell. Biol.* 67:465a; 1975.

3256 BLOOD COAGULATION STUDIES DURING ORTHOTOPIC LIVER TRANSPLANTATION IN PIGS. (Ger.) Muntean, W.; Rigler, B.; Stenzl, W.; Hermann, W.; Tentzeris, M. (Universitats-Kinderklinik Graz, Graz, Austria). *Acta Chir. Austriaca* 7(5):112-117; 1975.

3257 THE APPLICATION OF GUTHYMINE [GUANYLTHIOUREA] FOR TREATMENT OF INTESTINAL PARESIS IN PERITONITIS UNDER EXPERIMENTAL AND CLINICAL CONDITIONS. (Rus.) Timofeev, N. N.; Frolov, S. F.; Zhitniuk, R. I. (I. P. Pavlov First Leningrad Medical Inst., Leningrad, USSR). *Vestn. Khir.* 115(8):39-43; 1975.

3258 PURIFICATION OF LIPID EMULSIONS USED IN PARENTERAL FEEDING: LIVER PERFUSION STUDY IN ISOLATED RATS AND IN VIVO EXPERIMENT IN GUINEA PIGS. (Fre.) 3260 THE EVALUATION OF MALIGNANT GASTRIC NEOPLASMS BY ULTRASONIC B-SCANNING. (Eng.) Walls, W. J. (Univ. Kansas Medical Center, 39th St. and Rainbow Blvd., Kansas City, KS 66103). *Radiology* 118(1):159-163; 1976.

The diagnostic accuracy of ultrasonic B-scanning was evaluated in 11 patients with malignant gastric neoplasms, and its advantages and limitations were illustrated in three case reports. Surgery and histological findings demonstrated six true positive cases and two true negative cases, giving a diagnostic accuracy of 73%. Five true positive cases had gastric neoplasms that invaded the serosa via regional spread and presented as exogastric masses; they were detectable by ultrasound. There were three false negative studies. All patients in the true negative and false negative categories represented at least one of the three following situations: (a) the lesion infiltrated the mucosa and muscularis but did not thicken the gastric wall or extend far enough through the serosa to provide a detectable exogastric mass; (b) the lesion was located in the proximal fourth of the stomach, particularly the fundus and gastroesophageal junction; and (c) the patient had regional or distant metastases within the abdomen, but they were so small that areas of involvement were beyond the resolution of the ultrasonic equipment. It is concluded that diagnostic ultrasound is useful for evaluating patients with suspected malignant gastric neoplasm and it often complements the upper gastrointestinal series. In addition, demonstration of a mass by ultrasound is highly suggestive of exogastric extension, which is usually not demonstrable by other radiographic techniques or endoscopy.

3261 VASODILATORS IN THE CANINE MESENTERIC CIRCULATION: EVALUATION OF A POTENTIAL AID IN THE DIAGNOSIS OF GASTROINTESTINAL BLEEDING. (Eng.) Sovak, M.; Rosch, J.; Lakin, R. C. (Univ. California, San Diego, Sch. Medicine, La Jolla, CA 92093). *Invest. Radiol.* 10(6):595-607; 1975.

The radiodiagnostic potential of intra-arterially injected vasodilating agents was investigated in mongrel dogs. Their effect on total and segmental resistances (VR) of mesenteric vasculature, blood flow in the superior mesenteric artery and its bleeding branch, heart rate, and ventricular and systemic blood pressure was studied. Standard concentrations of test solutions were infused into perfusion tubing, either as a bolus or with a Harvard pump, to simulate the clinical situation. Dipyridamole, isoxsuprine, prochlorperazine, lidocaine, meglumine diatrizoate, and carbon dioxide were poor dilators. Phentolamine produced hypotension; glucagon and serpasil produced an extremely long dilation. A large and short vasodilation was produced with 1.5 mg/ml tolazoline and 0.03 mg/ml nylidrin, but both agents increased VR of the postcapillary segment and caused transient hypotension and arrhythmias; the side effects with nylidrin were smaller. Oxygen produced large and long vasodilation and minimal systemic effects. It is concluded that oxygen, or possibly nylidrin, are suitable agents when an intermittently bleeding mesenteric artery must be dilated for diagnostic purposes prior to angiography.

3262 ASSESSMENT OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) AND PURE PANCREATIC JUICE CYTOLOGY IN PATIENTS WITH PANCREATIC DISEASE. (Eng.) Hatfield, A. R. W.; Smithies, A.; Wilkins, R.; Levi, A. J. (London Hosp., Whitechapel, London, E1 1BB, England). *Gut* 17(1):14-21; 1976.

Pure pancreatic juice was collected from 61 patients with suspected pancreatic and biliary disease at the time of endoscopic retrograde cholangiopancreatography (ERCP) to evaluate this combined diagnostic approach for pancreatic disease. Final diagnoses in these cases included 26 with no detectable pancreatic disease, 9 with pancreatitis (5 relapsing and 4 chronic), and 26 with pancreatic carcinoma. A normal pancreatogram was obtained in 25 of the 26 normal subjects. A pancreatogram, obtained for eight of nine pancreatitis patients, showed changes compatible with pancreatitis in six. A pancreatogram was also obtained for 20 of the 26 pancreatic carcinoma patients. In 18 cases, radiological changes considered diagnostic of carcinoma were seen, and in 2 cases, changes suggestive of carcinoma were noted. Cytological studies on the group of 26 normal subjects revealed normal duct cells in all cases. Normal duct cells were also seen in all nine pancreatitis patients. However, in eight of these nine, numerous degenerate cells were noted. Malignant cells were seen in 14 of the 26 pancreatic carcinoma patients, and suspicious cytological findings were noted in an additional 3 patients. For the patients with pancreatic carcinoma, ERCP alone was diagnostic in 18 patients (65%); pure juice cytology alone was diagnostic in 14 patients (54%). When the results of ERCP and cytology were combined, a diagnostic conclusion was obtained in 24 of the 26 patients (92%). ERCP was of particular importance where proximal pancreatic tumors made cannulation impossible. In the six patients who had tumors obstructing the pancreatic duct rendering ERCP impossible, the addition of pure juice cytology converted a negative investigation into a diagnostic one. It is concluded that in pancreatic carcinoma, combined ERCP and pure juice cytology provide a rapid and safe pre-operative diagnosis, thus reducing the time of inpatient stay.

3263 SUCCESSFUL INTRAVENOUS CHOLECYSTOCHOLANGIOGRAPHY IN THE JAUNDICED PATIENT USING MEGLUMINE IODOXAMATE (CHOLOVUE). (Eng.) Robbins, A. H.; Earampamoorthy, S.; Koff, R. S.; Di Fazio, L. T.; Wickis, E. A.; Gertler, A. N. (Veterans Admin. Hosp., 150 South Huntington Ave., Boston, MA 02130). *Am. J. Roentgenol.* 126(1):70-76; 1976.

A clinical trial of meglumine iodoxamate (Cholovue) for i.v. cholangiocholecystography was performed in 18 patients with elevated levels of serum bilirubin. Ten to 30 cm^3 of a 40% aqueous solution of the agent were given i.v. over a 10-min period, and roentgenographic examinations were conducted to document the agent's effectiveness, to determine optimal dosage levels, and to assess its safety. The common bile duct was visualized in 12 of 18 cases, and the gallbladder was visualized in 14 cases. The agent was effective with bilirubin levels up to 6.5 mg percent. The optimal dose in patients with elevated bilirubin was in the range of 20 cm^3. No important adverse clinical nor laboratory reactions was observed. The new agent appears to offer a significant improvement over Cholografin, particularly for patients with elevated bilirubin levels.

3264 PROSPECTIVE, RANDOMIZED STUDY OF DIAGNOSIS AND OUTCOME IN ACUTE UPPER-GASTROINTESTINAL BLEEDING: ENDOSCOPY VERSUS CONVENTIONAL RADIOGRAPHY.

(Eng.) Morris, D. W.; Levine, G. M.; Soloway, R. D.; Miller, W. T.; Marin, G. A.; *et. al.* (Hosp. Univ. Pennsylvania, Philadelphia, PA). *Am. J. Dig. Dis.* 20(12):1103-1109; 1975.

The diagnostic accuracy of panendoscopy was compared prospectively with upper gastrointestinal (UGI) barium series by randomly assigning 60 patients with mild to moderate UGI hemorrhage to one of these diagnostic procedures. The clinical significance of using either as the initial procedure was also evaluated. Definitive localization of the source of bleeding was made initially in 69% of the endoscopy group and in 21% of the UGI group ($p<0.0005$). Of 54 patients who underwent both studies, endoscopy was definitive in 67% and UGI series was definitive in 22%. Thus, endoscopy also made more diagnoses when used as the second study ($p<.01$). The use of endoscopy as the initial procedure led to significantly more rapid diagnosis than with UGI series. However, there were no significant differences between the two groups in clinical outcome. Endoscopy is the initial diagnostic procedure of choice in patients with mild to moderate upper-gastrointestinal bleeding because it enables detection of superficial bleeding lesions and has significantly increased the speed of diagnosis.

3265 DIAGNOSIS OF CARCINOMA OF THE PAPILLA OF VATER BY DUODENOFIBERSCOPY: SIMULTANEOUS ATTEMPT ON ENDOSCOPIC OBSERVATION, ASPIRATION CYTOLOGY, RETROGRADE PANCREATOCHOLANGIOGRAPHY AND BIOPSY.

(Eng.) Harada, H.; Mandai, H.; Tsurumi, T.; Yamamoto, N.; Tomiyama, Y.; Hinofuji, T.; Mandai, M.; Kikuchi, T.; Taguchi, H.; Matsuo, K. (Okayama Univ. Medical Sch., 5-1, Shikada-machi, 2-chome, Okayama City, 700 Japan). *Gastroenterol. Jpn.* 10(1):6-19; 1975.

Carcinoma of the papilla of Vater was diagnosed by duodenofiberoscopy and an endoscopic pancreatocholangiography in 13 patients. Carcinomas were divided into three types. Type I contained lesions that were endoscopically observed as polypoid or papillary tumors of the major papilla, originating from the duodenal surface and sometimes accompanied by crater. Type II contained lesions that were endoscopically observed as marked swelling of the longitudinal fold with no pathological findings of the major papilla other than redness. This type originates from the ampulla or the intraduodenal bile or pancreatic duct. Type III contained lesions that were endoscopically observed as normal papilla of Vater or minimal swelling of the major papilla, originating from the ampulla. General fatigue was noted in 10 cases, jaundice in 5, intermittent jaundice in 6 others, and fever in 8. Laboratory tests showed serum bilirubin, 0.45-25.9 mg/dl; SGOT, 17-240 U; SGPT, 34-350 U; and serum alkaline phosphatase, 7.0-31.2 BLU. Hypotonic duodenography diagnosed type I lesions, showing polypoid or papillary tumor with uneven or granular surface of the major papilla. Type II lesions were shown as swelling of the papilla of Vater with smooth surface. Type III lesions were hardly diagnosed by this method at all. For type I lesions, endoscopic observation and biopsy were usually sufficient. Type II lesions were not confirmed by endoscopic observation alone, and biopsy was usually negative. Type III lesions required aspiration cytology and pancreatocholangiography. Carcinomas of the papilla of Vater with crater can be differentiated without difficulty from choledochoduodenal fistula. It is concluded that duodenofiberscopic examination is the most useful method for diagnosing carcinomas of the papilla of Vater, as it not only allows elucidation of the presence and malignant nature of the lesion, but it also allows localization of the lesion by simultaneously performing endoscopic observation, aspiration cytology, pancreatocholangiography, and biopsy.

3266 CHOLEGRAPHY-INDUCED ACUTE RENAL FAILURE: ITS RELATION TO SUBSEQUENT SURGICAL THERAPY.

(Eng.) Gleysteen, J. J.; Aldrete, J. S.; Rutsky, E. A. (Univ. Station, Dept. Surgery, Birmingham, AL 35294). *South. Med. J.* 69(2):173-176; 1976.

The case reports of three patients who developed acute renal failure shortly after receiving p.o. or i.v. cholegraphic agents are presented, and the pertinent literature is reviewed. Two patients required subsequent surgical intervention; one had cholecystectomy and common bile duct exploration, and the other had right hemicolectomy and cholecystectomy for coexistent gangrenous cholecystitis and appendicitis. The third patient had chronic active liver disease. In all three, the cholegraphic agents were given while the patients were dehydrated. Two patients required hemodialysis. In all three, renal function returned to normal and was not altered by the subsequent surgical intervention. The cause of this complication remains uncertain, but hepatic dysfunction and the combination of uricosuria and dehydration are possible factors. It is concluded that patients should be properly hydrated prior to the administration of cholegraphic agents. Surgical intervention, if necessary, can be performed safely after renal function has returned to normal.

3267 ANGIOGRAPHIC PATTERNS IN EXPERIMENTAL OBSTRUCTION OF THE SMALL BOWEL.

(Eng.) Wojtowicz, J.; Wirga, Z.; Wirga, E. (Poznon Medical Sch., Poznan 61-833, Szkolna 8/12, Poland). *Invest. Radiol.* 10(6):583-594; 1975.

Angiographic studies were conducted in four main types of low small bowel obstruction, which were experimentally induced in the rabbit, to assess the dynamics of arterial changes in the intestinal wall. The angiographic patterns during the first 48 hr after obstruction were analyzed. Twenty-three rabbits had simple obstruction, 16 had strangulation, 17 had intussusception, and 13 had created volvulus. The type and rate of progression of peripheral arterial changes depended upon the mechanics of intestinal obstruction. Patency, caliber, and course of the ileal branches of the superior mesenteric artery were disturbed at different stages of strangulation, volvulus, and intussusception, but remained unchanged in simple obstruction. Stretching and displacement of the arteriae rectae and connecting branches occurred corresponding to the degree of distension of the obstructed bowel. In the strangulated or twisted loop, these arteries were subject to rapid thrombotic changes beginning at the antimesenteric border. The villus arterial network and arterial plexus of the mucosal and submucosal layer underwent massive thrombosis and destruction a few hours after strangulation and during later stages of volvulus. Destruction of the mucosal vessels, caused by progressive necrosis of the mucosa, appeared in simple obstruction and intussusception after 48 hr. The site of the obstruction corresponded to the clear-cut border between various arterial patterns of the distended and collapsed segment. Although each type of obstruction showed some specific findings, the most characteristic and individualistic pattern consisted of a parallel arrangement of arcuate arteries at the mesenteric border in intussusception.

3268 ANGIOGRAPHY IN CROHN'S DISEASE REVISITED.

(Eng.) Brahme, F.; Hildell, J. (Veterans Admin. Hosp., San Diego, CA 92161). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 126(5):941-951; 1976.

A total of 123 angiograms were performed in 116 patients with Crohn's disease to evaluate angiography as a diagnostic tool. Angiography provided information on the presence and location of the lesions in Crohn's disease in more than 90% of the cases. Diagnostic failures were mainly due to paucity of changes in lesions of mild inflammatory activity. Many angiographic features are nonspecific; only the zoning sign and the presence of para-intestinal mesenteric neovasculature were considered diagnostic. These signs were present in 30% of the cases. Right angle branching was frequently difficult to evaluate, and thickening of the gut was observed in ulcerative colitis. The presence of ileal abnormalities was diagnostically helpful in ileocolic Crohn's disease, but other signs must be used in patients with colonic involvement exclusively. Among eight patients with Crohn's disease confined to the colon, a clearly recognizable zoning sign was present in five (15%), but distinguishing features were absent in three. Colitis, caused by Crohn's disease, was distinguished from ulcerative colitis by angiography in only 30% of the cases. However, angiography along with barium studies will reveal the presence of lesions. It is concluded that angiography is a potential differential diagnostic aid in doubtful cases of inflammatory and malignant bowel disease.

3269 LONGITUDINAL SINUS TRACTS IN GRANULOMATOUS COLITIS AND DIVERTICULITIS.

(Eng.) Marshak, R. H.; Lindner, A. E.; Pochaczevsky, R.; Maklansky, D. (1075 Park Ave., New York, NY 10028). *Semin. Roentgenol.* 11(2):101-110; 1976.

The x-ray features that usually distinguish granulomatous colitis from diverticulitis are described. The linear extent of the longitudinal sinus tract in diverticulitis is usually short (3-6 cm) and is located in the sigmoid section, while the tracts in granulomatous colitis tend to exceed 10 cm and can be located anywhere in the colon. In diverticulitis, the diverticula are sharply defined and often contain a fecalith, while in granulomatous colitis, the diverticula appears as a triangular abscess with cap-like configuration. The diverticular abscess of diverticulitis has an intramural defect or an arcurate configuration of stretched fold. In granulomatous colitis, the folds are thickened and edematous with increased secretions. There are no transverse fissures in diverticulitis, and the folds usually have arcurate configuration. Transverse fissures are present in granulomatous colitis and mucosal edema produces a stepladder configuration. The mucosa is normal in diverticulitis, while in granulomatous colitis there are mucosal ulcerations or cobblestoning. It is suggested that in approximately 20% of patients who have diverticulitis alone, granulomatous colitis is simulated by a long segment of disease, marked spasm and irritability, multiple perforations, or a long fistulous tract.

3270 QUANTIFICATION OF CARCINOEMBRYONIC ANTIGEN-LIKE ACTIVITIES IN NORMAL HUMAN GASTROINTESTINAL SECRETIONS.

(Eng.) Go, V. L. W.; Ammon, H. V.; Hoitermuller, K. H.; Krag, E.; Phillips, S. F. (Mayo Clinic, Rochester, MN 55901). *Cancer* 36(6):2346-2350; 1975.

Carcinoembryonic antigen-like (CEA-like) activity in gastrointestinal, pancreatic, and biliary secretions of 28 fasting normal men were quantified by using intestinal perfusion techniques, and the chromatographic and immunologic properties of the CEA-like material in these secretions were determined. CEA-like activity was detected at all levels of the gastrointestinal tract. The secretory rate from the colon was the highest (mean ± SE, 2.41 ± 2.0 μg/min), followed by that of pancreatobiliary and pancreatic secretions. The secretory rate from the stomach, duodenum, jejunum, and ileum was less than 20 ng/min. After perchloric acid extraction, the CEA-like material from the colon had the same chromatographic and radioimmunologic properties as [^{125}I]-CEA. These data suggest that the CEA-like material is normally secreted into the gastrointestinal tract, particularly into the colon.

3271 THE RADIOLOGIC DEMONSTRATION OF EARLY CHANGES IN ULCERATIVE COLITIS BY DOUBLE CONTRAST TECHNIQUE.

(Eng.) Laufer, I. (McMaster Univ. Medical Center, Hamilton, Ontario, Canada). *J. Can. Assoc. Radiol.* 26(2):116-121; 1975.

The double contrast technique was used in 70 patients to demonstrate radiologically early changes in ulcerative colitis. Twelve of the 70 patients were also examined with the flexible colonoscope, while all of the others were examined with the standard rigid sigmoidoscope. The radiologic diagnosis differed from the endoscopic findings in only 3 of 70 cases, even though the severity of disease in the rectosigmoid was often less than in more proximal portions of the bowel. In two patients with ulcerative proctitis where inflammation was limited to the distal 5-10 cm of rectum, the double contrast enema was normal. There were no complications attributable to the air contrast study. In a survey of patients who had previously been examined by a filled colon technique and subsequently by the double contrast technique, a majority of almost 2:1 found the air contrast study to be less distressing. The results indicate that subtle changes in the colonic mucosa due to medical treatment can be demonstrated by this method. It may be important for distinguishing between structural improvement in the bowel as opposed to the psychological well being that is induced by steroid treatment.

3272 LIPOPROTEIN X IN HEPATOBILIARY DISEASE. (Ger.) Mordasini, R. C.; Berthold, S.; Schlumpf, E.; Keller, H.; Riva, G. (Tiefenauspital, Tiefenaustrasse 112, CH-3004 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 105(27):863-872; 1975.

The diagnostic and prognostic reliability of lipoprotein-X (Lp-X) in the diagnosis of cholestasis was evaluated in 80 patients with diseases of the liver and/or the biliary tracts, and in 103 subjects with various other diseases. The results of Lp-X detection were compared with the so-called "enzymes indicating cholestasis:" alkaline phosphatase, leucine arylamidase, and γ-glutamyltranspeptidase. Where possible, a histologic specimen of the liver was obtained. The correlation between Lp-X and enzymes indicating cholestasis was satisfactory in over 90% of the cases. When compared with the histologic findings, Lp-X proved to be more reliable than the enzymes. However, Lp-X did not show absolute specificity in the detection of cholestasis, as there were several negative results in cases with histologically proven cholestasis. Furthermore, the differentiation of intra- and extrahepatic cholestasis was not possible on the basis of Lp-X. In the control group, three were Lp-X-positive. Further investigations in these three patients revealed that primarily unsuspected hepatobiliary disease could not be ruled out. Follow-up of patients with hepatobiliary disease showed that the transition of Lp-X to negative indicated improvement of cholestasis 1-2 weeks earlier than using the enzymes mentioned above.

3273 THE RESPONSE OF THE LOCAL IMMUNOGLOBULIN SYSTEM TO MALIGNANT LESIONS OF THE STOMACH: A NEW DIAGNOSTIC TEST. (Eng.) Levy, M.; Petreshock, E. P.; Mandell, C.; Deysine, M.; Katzka, I.; Aufses, A. H., Jr. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Cancer* 36(6):1991-1995; 1975.

The response of the local secretory immunoglobulin system to tumor antigens was studied in 71 patients suspected of harboring a gastric malignancy. Gastric aspirates were obtained by fiberoptic endoscopy and measured on single radial immunodiffusion plates. Patients with malignant neoplasms of the stomach were divided into type I and type II lesions based upon the extent and stage of the disease. Secretory immunoglobulin (Ig) A titers were elevated in all patients with type I malignant tumor confirmed by histologic examination: mean, 43.8 mg/100 ml (standard deviation ± 40.6 mg/100 ml). Patients with type II malignant lesions, benign lesions or normal controls had significantly lower IgA titers: mean, 6.1 mg/100 ml (SD ± 3.7 mg/100 ml). This suggests that the host's response to malignant cells of the gastrointestinal system is an altered and elevated secretion of IgA. Evaluation of local immunoglobulin titers may be of value when used in conjunction with other diagnostic modalities in determining the nature of gastrointestinal lesions, particularly when the lesion is not metastatic or does not massively involve the gastric wall.

3274 ^{131}I ROSE BENGAL SCANNING AND CLEARANCE RATIOS IN THE INVESTIGATION OF JAUNDICED PATIENTS. (Eng.) Davies, E. R.; Morris, J. N.; Read, A. E.; Powell, N. (Univ. Dept. Medicine, United Bristol Hosps., U.K.). *Clin. Radiol.* 27(2):227-235; 1976.

The accuracy of the ^{131}I-rose bengal test in distinguishing between obstructive and nonobstructive jaundice was assessed in 70 jaundiced patients. Blood clearance traces, intestinal radioactivity traces, and serial abdominal scans were performed during a 3-hr period. The blood clearance ratios were not helpful discriminators, while the timing of intestinal radioactivity was the most helpful information. Its rapid appearance excluded mechanical obstruction. A delay of up to 3 hr in its appearance was characteristic of cholestasis. A delay of over 3 hr, found in all cases of mechanical obstruction, was also noted in 10 cases of severe cholestasis that could not be distinguished from those with mechanical obstruction. A follow-up examination within 10 days was of diagnostic value in two of these cases, and the overall accuracy of the test was 86%. It is concluded that the ^{131}I-rose bengal test is a helpful diagnostic discriminator in the great majority of patients with jaundice. It is offered as a screening procedure for specialized techniques.

3275 CORRELATION BETWEEN ISOTOPIC SCANNING AND PANCREATIC FUNCTION TESTS IN THE DIAGNOSIS OF PANCREATIC DISEASES: IMAGE AND DIGITAL COMPUTER TECHNIQUES. (Eng.) Fruhling, J.; Vincent, J. L.; Van der Hoeden, R.; Delcourt, A. (Institut J. Bordet, B-1000, Bruxelles, 1 rue Heger-Bordet, Belgium). *Int. J. Nucl. Med. Biol.* 2:145-152; 1975.

The effectiveness of the secretin-cerulein (or CCK) pancreatic function tests was compared with that of scintigraphy in 70 subjects to determine whether there is a correlation between the results of the two diagnostic methods. The Anger-camera was used for studying liver and gastrointestinal activity. The functional test measured secretory volume, bicarbonate concentration and output, and enzyme output, under secretin and pancreozymin stimulation. There was a good correlation between the final conclusion of functional investigation and the definitive protocol of the radionuclide pancreatic study. In 60 of the 70 cases (86%), results of both examinations were in agreement. Among the four functional parameters, the enzyme output showed results nearest to the scintigraphic image. Interpretation of results by evaluating the scintigraphic image and pancreatic function test has the advantage of correcting false positive results, which are obtained by either of the two methods used alone. In this study, there were no false negative results to be corrected. Thus, it is concluded that the two methods may have equal value in demonstrating pathologic findings of the pancreas.

3276 THE SIGNIFICANCE OF THERMOGRAPHY IN THE DIAGNOSIS OF ACUTE ABDOMINAL DISEASE. (Eng.) Peltokallio, P.; Svinhufvud, U.; Rantakaulio, M.; Varjoranta, K. (Univ. Helsinki, Haartmanink 4, Helsinki, Finland). *Amer. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):164-171; 1975.

The use of thermography in the diagnosis of acute appendicitis, acute cholecystitis, and abscesses in the abdominal cavity was investigated during the examination of 100 patients with acute abdominal disease. In 41 cases in the acute biliary group, thermography yielded findings supporting the diagnosis in 24 patients (59%), insignificant findings in 14 patients (34%), and findings that were misleading in 3 patients (7%). In the appendicitis group, thermographic results supported the diagnosis in 17 (63%), were insignificant in 6 (22%), and misleading in 4 cases (15%). In the abscess/tumor group, thermographic findings supported the diagnosis in 16 patients (50%), were insignificant in 11 patients (35%), and misleading in 4 patients (12%). Also, thermography was the sole source of diagnosis in the case of a 52-yr-old man with distinct signs suggesting a periappendicular abscess. There were nine tumors of the cecum and ascending colon in which a very clear thermographic finding supporting tumor diagnosis was obtained. All had palpable resistance in the lower right abdomen. Thermographic examination supported the tumor versus abscess diagnosis in half of the patients. In all three groups, misleading test results were obtained in patients who were obese and had thick abdominal covers. It is suggested that thermography has significance in the diagnosis of acute abdominal disease, as an aid to existing examinations. Thermography should also have an obvious application in the localization of postoperative suppurative foci.

3277 CONTRIBUTION OF ARTERIOGRAPHY TO THE DIAGNOSIS OF MALIGNANT TUMORS OF THE BILE DUCTS. (Fre.) Geindre, M.; Coulomb, M.; Marty, F. (C.H.U. de Grenoble, F 38700 La Tronche, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9):602-603; 1975.

GASTROINTESTINAL DISEASES

ESOPHAGUS

3317 EPIDEMIOLOGY OF OESOPHAGEAL CANCER IN FRANCE: INCREASING MORTALITY AND PERSISTENT CORRELATION WITH ALCOHOLISM. (Eng.) Audigier, J. C.; Tuyns, A. J.; Lambert, R. (Hopital Edouard-Herriot, place d'Arsonval, F-69374 Lyon Cedex 2, France). *Digestion* 13(4):209-219; 1975.

The geographic distribution of esophageal carcinoma in France, its time trend, and a possible correlation with alcoholism were investigated. For the year 1967-1968, 10,237 deaths from esophageal cancer were reported in France. The disease was much more common in men, with the sex ratio of 12.88:1. For men, the incidence was particularly high in three western provinces: Normandie, Bretagne, and Pays de la Loire. From the years 1961-1963 to 1967-1968, an increase of 8% in the number of men afflicted with this disease was found for the whole of France. In women, the rate of incidence did not change. Correlation coefficients were calculated between esophageal cancer, cirrhosis, and alcoholism. These demonstrate a marked correlation in men with cirrhosis and alcoholism. The correlation found with alcoholism was higher and appeared in all age groups. In women, the result was not so clear, but there was a correlation with cirrhosis mortality in the age group 65-74. The relation of alcohol in the etiology of esophageal cancer in France is confirmed by this strong and persistent correlation between esophageal cancer mortality and mortality from cirrhosis and alcoholism. The mechanism by which alcohol consumption induces esophageal cancer is closer to that leading to alcoholism and alcoholic psychosis than to that resulting in liver cirrhosis. It is suggested that for cancer of the esophagus, alcohol may be one specific carcinogen.

3318 ESOPHAGEAL REFLUX--AN UNRECOGNIZED CAUSE OF RECURRENT OBSTRUCTIVE BRONCHITIS IN CHILDREN. (Eng.) Danus, O.; Casar, C.; Larrain, A.; Pope, C. E., II. (Hospital Roberto del Rio, Santiago, Chile). *J. Pediatr.* 89(2):220-224; 1976.

Forty-three children (aged 4 months-5 yr) with recurrent obstructive bronchitis but without prominent gastrointestinal symptoms were studied roentgenographically and by manometry for esophageal reflux. Roentgenographic evidence for reflux was observed in 26 patients; these patients had a mean lower esophageal sphincter (LES) pressure of 6.3 mm Hg as compared to a mean LES pressure of 21.9 mm Hg in 10 normal control infants. The remaining 17 patients had a mean LES pressure of 10.0 mm Hg, also significantly lower than that of control subjects. Fifteen of 20 patients with recurrent obstructive bronchitis noted alleviation of their pulmonary symptoms after medical treatment of their reflux. Sequential studies of another group of 21 patients with radiologically demonstrated reflux who were followed for 6 months showed increases in sphincter pressures and disappearance of radiologically observed reflux in one-third of the patients. It is suggested that esophageal reflux should be sought in patients with recurrent bronchitis, and that antireflux therapy might improve the pulmonary symptomatology.

3319 HIGH PEPTIC STRICTURE OF THE OESOPHAGUS. (Eng.) Davidson, J. S. (Bradford Royal Infirmary, Duckworth Lane, Bradford, West Yorkshire, BD9 6RJ, U.K.). *Thorax* 31(1):1-14; 1976.

A clinical account of high peptic stricture with the lower esophagus lined by columnar epithelium of gastric type, is reported in 57 patients. In 42 of the patients, the strictures were at the level of the aortic arch. In 15 patients, strictures were located not lower than midway between the aortic arch and the hiatus. There was little difference in symptoms between high and low strictures. Radiologically, most of the high strictures were short and smooth, but other types were also illustrated. Carcinoma and congenital mid-esophageal web were considered in the differential diagnoses. Duodenal ulcer was associated in 10% of the cases. A high stricture developed soon after an abdominal operation or period of recumbency in six patients. A Barrett ulcer was noted, in addition to a high stricture, in one patient. In one patient, the mucosa of the lower esophagus appeared to be replaced by jejunal mucosa, following esophagojejunostomy. A stricture was noted to be ascending the esophagus, over a period of 6 yr, in one patient. Treatment by dilatation was performed in 33 patients; 24 underwent surgery. Hernial repair appears to be an effective method of treatment when no pathology is found in the region of the pylorus and duodenum. However, if such pathology is present, it is suggested that vagotomy be included in the treatment procedure. Of the 19 patients who were treated with hernial repair, significant dysphagia persisted in 2 and slight dysphagia persisted in one.

3320 EFFECT OF PENTAGASTRIN AND GASTRIC ALKALINIZATION ON LOWER ESOPHAGEAL SPHINCTER PRESSURE IN DIFFUSE ESOPHAGEAL SPASM. (Eng.) Eckardt, V. F.; Holtermuller, K. H. (Lemuel Shattuck Hosp., 170 Morton St., Boston, MA 02130). *Digestion* 13(1/2):1-7; 1975.

The effect of i.v. pentagastrin and gastric alkalinization on the lower esophageal sphincter (LES) pressure was evaluated in seven patients with diffuse esophageal spasm and was compared with responses in nine normal controls. Injections of 0.2 and 0.4 μg pentagastrin/kg increased LES pressure significantly more in patients than in control subjects ($p<0.05$, $p<0.01$). Following gastric alkalinization with 5 ml of 0.1 N $NaHCO_3$/min (over 20 min), both groups showed increases in LES pressure, but these were significantly greater for patients with diffuse esophageal spasm ($p<0.05$) than for controls. The results indicate that the LES in patients with diffuse esophageal spasm is supersensitive to pentagastrin and gastric alkalinization.

STOMACH

3342 ENDOSCOPIC DIAGNOSIS OF ADVANCED GASTRIC CANCER: FACTORS INFLUENCING YIELD. (Eng.) Winawer, S. J.; Posner, G.; Lightdale, C. J.; Sherlock, P.; Melamed, M.; Fortner, J. G. (Memorial Hosp., 1275 York Ave., New York, NY 10021). *Gastroenterology* 69(6):1183-1187; 1975.

Factors that influence diagnostic yield by directed endoscopic biopsy and cytology were studied in 50 patients with advanced gastric cancer, using a forward-viewing panendoscope. Cytological and/or histological confirmation of carcinoma was obtained in 92% of the 26 exophytic tumors but in only 50% of the 24 that were infiltrative, for an overall diagnostic yield of 72%. There was a positive yield of 85% for brush cytology alone compared to 65% for biopsy alone, in exophytic lesions; and there was a positive yield of 50% for brush cytology alone compared to 33% for biopsy alone, in infiltrative lesions. The overall yield for brush cytology alone was 68% compared to 50% for biopsy alone. The lesions that provided non-diagnostic tissue were mostly recurrent or infiltrative cancers, and were most often in the cardia, antrum, or were of the linitis plastica type. The combination of infiltrative character and location in antrum or cardia, especially if recurrent, often resulted in nondiagnostic biopsy and cytology specimens. It is concluded that currently available fiberoptic endoscopes generally provide a fairly high degree of diagnostic accuracy for certain types of gastric cancers and that addition of cytological techniques has also increased the diagnostic yield.

3343 VARIATION IN DISTRIBUTION OF ANTRAL GASTRIN CELLS. (Eng.) Asnoes, S.; Johansen, A. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Acta Pathol. Microbiol. Scand. (A)* 83(6):737-738; 1975.

The variation in distribution of gastrin-producing cells was studied by an immunoperoxidase technique in biopsy specimens from 65 patients with gastric disorders. The number of gastrin cells varied considerably in the pyloric mucosa. Illustrations of four biopsies taken from a small area of antral mucosa in a patient with atrophic gastritis are presented; the number of gastrin cells varies from 1 to 165 per biopsy. It is concluded that estimating the gastrin cell mass from a small number of biopsies is very difficult and that the variation of the number of cells at different stages of gastritis must be determined.

3344 PRACTICAL SIGNIFICANCE OF GASTRIC RUGAL FOLDS. (Eng.) Press, A. J. (Lankenau Hosp., Lancaster and City Line Ave., Philadelphia, PA 19151). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):172-183; 1975.

The practical value of gastric fold assessment was studied in 33 cases of gastric carcinoma and in 47 cases of gastric or duodenal ulcer. Older patients with carcinomas fell into the lowest atrophic grouping; however, younger patients (below 60 yr of age) with carcinomas may have rugose stomachs, a condition that is more commonly found in the elderly patient. In normal patients, some proportionality of gastric folds to acid output was found to exist. Such a correlation may also be present in cases of peptic disease of the distal stomach or duodenum. A local area of gastric fold exaggeration reflected tumor or inflammation in specific cases. Hyperrugosity with a "bland" duodenum suggested underlying chronic mucosal disease, possibly of diverse etiology, but with low acid output, as contrasted with the "reactive" duodenum reflecting a more normal or increased acid output. Gastric atrophy consistently aroused a high suspicion of any lesion, especially in the diagnosis of "chronic peptic scarring." A possible upper limit of "physiologic" fold thickness was reported at 4 to 5 mm, beyond which an additional pathologic process was inferred. It is suggested that hypertrophic gastritis and gastric body ulcer disease may illustrate this progression and possibly share similar underlying mucosal pathology and rugal characteristics.

3345 THE EFFECT OF BETA-ADRENERGIC BLOCKADE UPON BASAL AND PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION AND UPON GASTRIN RESPONSE TO FOOD. (Eng.) Kronborg, O. (Bispebjerg Hosp., Kajerodvej 124, 3460 Birkerod, Denmark). *Scand. J. Gastroenterol.* 10(7):757-762; 1975.

The effects of β-adrenergic blockade with propanolol on the spontaneous and maximum gastric acid secretion and on gastrin response to food were investigated in normal subjects and in duodenal ulcer patients. In spontaneous secretion studies, propanolol did not affect acidity, and the total acid output during 2 hr after propanolol was similar to that before the drug was administered. The pulse rate was significantly decreased. In spite of a significant β-adrenergic blockade, maximum secretion was not changed by 5 mg propanolol. At 10 mg, a reduction in maximum acid output was seen in all of seven healthy subjects and in four of five ulcer patients. However, acidity changes were insignificant. Serum gastrin concentrations in normal subjects after food ingestion were insignificantly higher after propanolol during the period from 140 to 210 min. However, at 210 min this difference became significant. The 5 duodenal ulcer patients had a higher gastrin response than the 10 normal subjects, but the response after propanolol and placebo were not significantly different. Blood glucose concentrations increased to the same degree after food in both normal and ulcer subjects. The results support a stimulation of β-receptors during pentagastrin infusion. The insignificantly higher gastrin concentration after a meal, during β-blockade, suggests a reduced antral suppression by acid causing a gastrin release. An adrenergic gastrin response to food, which may be inhibited by β-bloackage, was not demonstrated in this study. Gastrin response to food was apparently not directly related to activation of β-adrenergic receptors.

3346 GASTROINTESTINAL CANCER: ITS GEOGRAPHIC DISTRIBUTION AND CORRELATION TO BREAST CANCER. (Eng.) Jansson, B.; Seibert, G. B.; Speer, J. F. (M.D. Anderson Hosp. and Tumor Inst., Houston, TX). *Cancer* 36(6):2373-2384; 1975.

Maps of mortality rates in all U.S. counties for cancer of the stomach, colon, and rectum are presented and the relation between large bowel cancer and all other cancer sites is analyzed in terms of geographic distribution and geographic variation. Highest colon and rectum cancer rates are concentrated in the northeast and north central United States with the Ohio River as an especially sharp boundary between high and low rate counties. The distribution rates of stomach cancer are particularly high in New Mexico, North Dakota, and around Lake Superior. This supports the possibility of chemical protectors (e.g., selenium), which affect the rates of colon and rectum cancers in the United States. The urban-rural differences, which had been observed in the past, are not readily apparent. Evaluation of all cancer sites demonstrates that the geographic dependence was highest for organs most exposed to the environment, such as the organs along the alimentary canal, and it is lowest for unexposed organs such as prostate, pancreas, and brain. The correlation coefficients between mortality rates for cancer of different organ sites are grouped in subsets with high correlations for each pair in the same subset. Cancers of colon, rectum, and breast are highly correlated in United States data as well as in international data. The analyses suggest that new epidemiologic studies may be helpful in further elucidating the interrelation between the factors suspected to be involved in the cause of large bowel cancer.

3347 GASTRIC ULCER AND CANCER. (Eng.) Montgomery, R. D.; Richardson, B. P. (East Birmingham Hosp., Birmingham, B9 5ST, England). *Q. J. Med.* 44(176):591-599; 1975.

The incidence of gastric carcinoma was studied in a series of 210 patients presenting with apparently benign gastric ulcer. Ten cases underwent immediate surgery. The remainder, most of whom were treated with carbenoxolone, were followed up as outpatients for periods of 2-13 yr. During this time, additional 75 patients had elective surgery. In all, there were 78 gastrectomies and 7 vagotomies with pyloroplasty. In nine cases, carcinoma was diagnosed within 18 months and was almost certainly present from the outset. Superficial spreading carcinoma was detected by histology, four cases after routine gastrectomy, which revealed no gross evidence of malignancy. Four cases of unsuspected superficial spreading carcinoma were found in a total of 74 gastrectomy specimens. Altogether, 8 cases of carcinomatous ulcer were initially misdiagnosed in a series of 210. In five of these patients operation was delayed for more than 3 months. The 5-year death rate due to gastric carcinoma was 3.2% for the whole series. The operative mortality for elective surgery was 1.3%. The mean follow-up was 5.7 yr for the remaining 201 cases. Three fresh cases of gastric carcinoma were found, and in two of these, the cancer was at a different site from the ulcer. The 5-yr incidence of fresh gastric carcinoma was 0.6%. Unsuspected superficial spreading carcinoma was detected by histology in 5.4% of gastrectomy specimens. It is concluded that there is a need for vigilance, both in family practice and in hospital, in the detection and assessment of fresh gastric ulcers at the earliest stage of their evolution.

3348 GASTRIC ULCER AND CARCINOMA IN FUNDIC GLAND AREA. (Eng.) Yamagiwa, H.; Ishihara, A.; Hamazaki, M. (Mie Univ., Sch. Medicine, 174 Edobashi 2-chome, Tsu, Japan). *Gastroenterol. Jpn.* 10(4):290-299; 1975.

The clinicopathologic findings of the ulcer and carcinoma in the fundic gland area are compared with those in the pyrolic gland area in surgically resected tissue. The frequency of ulcer in the fundic gland area was 8.2% in 2,194 cases of gastric ulcer and that of carcinoma was 8.4% in 780 cases of gastric carcinoma. Both diseases showed high frequency in the 40-50 yr age group, and were common in females. Ulcers in the fundic gland area usually showed high acidity and high frequency of massive bleeding, as melena and hematemesis in 19 of 82 cases (23%). In contrast, in carcinoma of the fundic gland area, the acidity was usually low and the massive bleeding was seen in 20%. The ratio of low differentiated carcinomas to well differentiated ones was about 3.7:1 in the fundic gland area and 1:1.3 in the pyrolic gland area. The frequency of early gastric carcinomas was 27% and 41% in the fundic and pyrolic gland areas, resp. In the fundic gland area, as in the pyrolic gland area, the low differentiated carcinomas usually occurred on the nonmetaplastic mucosa and the majority of well differentiated ones were found in association with the intestinal metaplasia. Although the solitary carcinoma in the anterior wall or greater curvature was observed, the solitary ulcer was not found in these sites in this series. The results indicate that the pathology of ulcers in the fundic area is similar to that of ulcers in the pyrolic gland area.

3349 GANGLIOSIDE PATTERN AND NEURAMINIC ACID CONTENT OF HUMAN GASTRIC AND COLONIC CARCINOMA.

(Eng.) Keranen, A.; Lempinen, M.; Puro, K. (Dept. Medical Chemistry, Univ. Helsinki, Siltavuorenpenger 10A, SF-00170 Helsinki 17, Finland). *Clin. Chim. Acta* 70(1):103-112; 1976.

The ganglioside pattern of 25 human gastric and 11 human colonic adenocarcinomas was analyzed to determine whether the ganglioside pattern and neuraminic acid content of human malignant tissue differ from those of normal tissue. Most of the gastric tumors and all of the colonic tumors contained about four times more lipid-bound neuraminic acid, i.e., gangliosides, than corresponding normal tissue. The ganglioside pattern seemed normal in all of the tumors. No differences were found between the ganglioside compositions of human gastric and colonic adenocarcinomas and corresponding normal mucosas. The total amount of gangliosides was increased about fourfold in malignant tissues. The amount of protein-bound neuraminic acid was higher (up to 22.6 μmol/100 g) than normal in all gastric carcinomas examined. In the colon carcinomas, it was high in most, but low in some ranging from 170 to 814 μmol/100 g (normal=310 μmol/100 g). The ratio of lipid-bound neuraminic acid content (L) to protein-bound neuraminic acid content (P) was chosen as the common denominator for the grouping of the carcinoma material. The six gastric carcinomas with an L/P ratio lower than normal gastric mucosa (<2.5%) were significantly larger than those having an L/P ratio within normal limits (2.5-4.4%) or higher (>4.4%) than normal tissue. In this group, the content of protein-bound neuraminic acid was increased, as in the total material, but the content of lipid-bound neuraminic acid was decreased. The relevance of these findings is not clear at present.

3350 HETEROGENICITY IN SUSCEPTIBILITY TO CHRONIC GASTRITIS IN RELATIVES OF GASTRIC CANCER PATIENTS WITH DIFFERENT HISTOLOGY OF CARCINOMA.

(Eng.) Kekki, M.; Ihamaki, T.; Sipponen, P.; Hovinen, E. (Dept. Medicine, Haartmaninkatu 4, 00290 Helsinki 29, Finland). *Scand. J. Gastroenterol.* 10(7): 737-745; 1975.

The morphological state of gastric body mucosa was examined in 269 first degree relatives of 64 index patients with gastric carcinoma and in 142 randomly selected subjects. Gastric carcinoma was divided into three groups according to histological properties: carcinoma mucocellulare, carcinoma adenomatosum, and carcinoma anaplasticum. The state of gastric body mucosa was divided into five states: normal, superficial gastritis, slight, moderate, and severe atrophic gastritis. The results were subjected to numerical analysis based on the stochastic theory. The term age-adjusted score (AAS) was used to define the individual susceptibility to chronic gastritis. In terms of AAS, the material was divided into high and low gastritis risk families. The subjects belonging to carcinoma mucocellulare index patient families had a significantly higher ($p<0.01$) susceptibility to chronic gastritis than the other relatives examined. These families were also significantly ($p<0.001$) concentrated in the group of high risk families. It is suggested that the heterogeneity of the relatives of gastric cancer patients, as regards their gastritis risk, should be taken into account in future epidemiological studies. These findings constitute further justification of the genetic approach in studies of the gastritis-gastric cancer relationship.

3351 GASTROINTESTINAL CHANGES IN PATIENTS WITH HYPOGAMMAGLOBULINEMIA.

(Eng.) Horoszek-Maziarx, S.; Kryszewski, A.; Lehman-Borowska, J.; Rynkiewicz, H.; Bardzik, I.; Krupa-Wojciechowska, B. (Inst. Internal Medicine, Medical Acad. in Gdansk. Gdansk, Poland). *Pol. Med. Sci. Hist. Bull.* 15/3(5/6):561-566; 1975.

Three cases of hypogammaglobulinemia are described. In all cases, the first symptoms of disease were pulmonary infections preceded by diarrhea. Diarrhea could have been caused by changes in the stomach as well as in the small intestine. Histamine fast anacidity was found and biopsy examinations of gastric mucosa disclosed atrophic gastritis. The strikingly thin gastric mucosa, devoid of parietal and chief cells, made it similar to the mucosa of the small intestine. In the first case, there was an increased number of lymphatic nodules in large parts of the digestive tract, usually without or with only small germinative centers. The xylose test and glucose loading test showed normal values. Schilling's test demonstrated impaired intestinal absorption of vitamin B_{12}. In all patients, there was a low iron level in the serum and a flat curve of serum iron after oral loading; the normal iron binding capacity by the serum indicated impairment of intestinal absorption. There was an absence of immunoglobulin (Ig) A in the serum; this may be the primary common cause of digestive tract changes, since IgA is the main Ig secreted into the digestive tract lumen, and plasma cells in the intestinal mucosa are its principal source. It is concluded that in patients with primary hypogammaglobulinemia showing mainly IgA deficiency, disturbances are found in the structure and functions of the digestive tract with atrophic gastritis, histamine fast anacidity, and impaired intestinal absorption.

3352 EFFECTS OF PARENTERAL ALIMENTATION ON POSTOPERATIVE GASTRIC FUNCTION. (Eng.)

Byrd, H. S.; Lazarus, H. M.; Torma, M. J. (Univ. Utah Medical Center, 50 North Medical Drive, Salt Lake City, UT 84132). *Am. J. Surg.* 130(6):688-693; 1975.

The effects of parenteral hyperalimentation on postoperative gastric function were studied in 11 patients undergoing abdominal aortic surgery. Five patients received standard isotonic postoperative i.v. solution, vitamins, and an electrolyte solution. The other six received parenteral FreAmine® and hypertonic glucose solution, providing 2,500 kcal and 16 g nitrogen/day. A positive nitrogen balance was accomplished in patients in the hyperalimented group. Excluding patients with gastric bleeding, gastric cell exfoliation rates were similar between patients in control (8.5×10^5 cells/min) and hyperalimented (8.9×10^5 cells/min) groups both pre- and postoperatively. In the three patients who had gastric bleeding on the third postoperative day, the corresponding abrupt increase in exfoliation rates of two of the patients to 8.5×10^6 cells/min a slough or shed of injured gastric surface epithelial cells. In response to the stress of surgery, a marked decrease occurred in gastric volumes of all patients, from 80.6 to 12.8 ml/hr for controls and from 68.9 to 6.5 ml/hr for hyperalimented patients. Total acid secretion was generally decreased in both groups, but was less clearly differentiated. However, hyperalimented patients had a gradual increase in acid secretion, achieving normal range between the third and fourth postoperative days. Control subjects were less predictable. Thus, it appears that the postoperative patient can be placed in positive nitrogen balance, and the stress of surgery apparently does not alter gastric cell exfoliation rates as long as the basic nutritional requirements are provided. However, in the postoperative semistarved patient, some derangement of the protective mucosal mechanism or the basic metabolic processes of the surface epithelial cells exists. It is concluded that parenteral hyperalimentation augments gastric mucosal regeneration, allowing for more physiologic secretory patterns and the maintenance of the protective gastric mucosal mechanism.

3353 JEJUNOGASTRIC INTUSSUSCEPTION FOLLOWING GASTRIC SURGERY. REVIEW OF THE LITERATURE AND REPORT OF TWO CASES. (Eng.)

Makris, G.; Galanis, N.; Koutsikos, S.; Giannakos, V.; Dalainas, V. (Univ. Thessaloniki, Medical Sch., Thessalonika, Greece). *Chir. Gastroenterol.* 9(1):93-98; 1975.

Two cases of jejunogastric intussusception following gastric surgery are presented. The two male patients presented, 14 and 20 yr resp., after Billroth II gastrectomy with epigastric pain and vomiting of food, bile, and blood. Gastrotomy was necessary only in the first patient. In this patient, there was invagination of the efferent loop, and the intussuscepted loop was long. The second patient underwent surgery 3 yr previously to correct rapid gastric emptying, and three nylon sutures encircling the serosa were used to constrict the lumen. The common feature, in both cases, was the massive hematemesis in the absence of melena. Both patients have maintained good health, following reduction of hematemesis.

3354 GASTRIC MUCOSA AFTER PARTIAL GASTRECTOMY. (Eng.)

Pulimood, B. M.; Knudsen, A.; Coghill, N. F. (West Middlesex Hosp., Isleworth, Middlesex, TW7 6AF England). *Gut* 17(2):463-470; 1976.

Histological changes in the body mucosa of the gastric remnant were investigated in 146 patients with peptic ulcer 2 yr after partial gastrectomy. Postoperative gastric biopsy specimens were compared with those at the time of operation. Of 138 patients without body atrophic gastritis (AG) before operation, this condition was found in 74 ($p<0.005$) 2 yr after operation [46% of duodenal ulcer (DU) patients and 73% of gastric ulcer (GU) patients]. The difference in the postoperative rates of AG in DU and GU was significant ($p<0.025$). The difference in the postoperative rates of AG in DU patients and in those with body GU was significant ($p<0.025$). Those with antral or pyloric canal ulcers were particularly liable to develop AG (81%). There was a marginally lower incidence of AG after ordinary Polya partial gastrectomy, when a Hofmeister value was incorporated ($p>0.05$). In DU's, there was a higher incidence of AG 2 yr after operation in men (51%) than in women (33%, $p>0.05$). A similar ratio was found for metaplasia in DU's (46% and 37%, resp.). There was an even chance of developing hypochromic anemia associated with AG, but at the time of biopsy, 88% of patients with AG were not anemic. Gastric parietal cell antibodies were not found in any patient with AG. The results indicate that there is no particular relation between the type of operation and age, postoperative appetite, body weight dumping, and diarrhea.

3355 USE OF ROUX-EN-Y DIVERSION OF DUODENAL SECRETIONS IN THE TREATMENT OF REFLUX GASTRITIS. (Eng.)

Bushkin, F. L.; Wickbom, G.; Woodward, E. R. (Coll. Medicine, Univ. Florida, Gainesville, FL 32610). *South. Med. J.* 69(2):132-137; 1976.

Roux-en-Y diversion of duodenal secretions was evaluated as treatment for postoperative reflux gastritis in 15 patients. All patients underwent surgery originally for benign ulcer disease; seven had a Billroth II gastric resection, six had a Billroth I gastric resection, and two had a vagotomy and pyloroplasty. Three of the patients had Henley jejunal loop interpositions, but their symptoms continued. The time between initial operation and the Roux-en-Y technique ranged from 1 to 22 yr. All patients showed marked subjective improvement within the first few weeks after operation. The hypochlorhydria or achlorhydria, which was present before revision, was essentially unchanged. Gross endoscopic improvement of the gastric remnant was noted in all 15 patients. Biopsy revealed a return to a more normal gastric mucosa in 14 of the 15 patients. It is concluded that the Roux-en-Y procedure is a technically simple method, has a low morbidity, and provides dramatic, expeditious relief of symptoms. After this procedure is performed, further revisional surgery is rarely necessary.

3356 SELECTIVE AND HIGHLY SELECTIVE VAGOTOMY WITH AND WITHOUT GASTRIC DRAINAGE. (Eng.) Cooperman, A. M. (Cleveland Clinic, Cleveland, OH). *Cleveland Clin. Q.* 43(2):51-60; 1976.

Two surgical procedures, selective gastric vagotomy (total gastric denervation) and highly selective vagotomy (partial gastric denervation) are reviewed. The advantages of selective vagotomy over truncal vagotomy include better results with postoperative Hollander tests and less diarrhea. In addition, there is a higher incidence of dumping and a drainage procedure may be omitted if obstruction is absent. Patients who undergo this procedure should be followed closely because gastric stasis requiring a drainage procedure may develop. After highly selective vagotomy, a newer operation, the results of secretory studies are satisfactory and there is a very low incidence of diarrhea, dumping, and other gastrointestinal complications when compared to other ulcer operations. However, the longest follow-up has been only 4 yr so its long-term value has not yet been evaluated.

3386 RESPONSE TO JEJUNAL ACIDIFICATION IN MAN. I. CHANGES IN COMPOSITION OF PERFUSATE. (Eng.) Thjodleifsson, B.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee, Scotland). *Scand. J. Gastroenterol.* 11(3):273-281; 1976.

The jejunal reaction to intraluminal acid was studied in 11 control subjects and in 12 duodenal ulcer patients. The study revealed that the human jejunum can dispose of large amounts of acid, and that the mechanism whereby acid is removed from the jejunal lumen involves buffering with bicarbonate secreted by the jejunal mucosa. Results indicate that the rate of secretion of bicarbonate into the jejunum is determined, in some manner, by the magnitude of the intraluminal stimulus provided by the acid, but that the maximal capacity to secrete bicarbonate per unit length of jejunum is limited. The amounts of bicarbonate, which can be secreted by 30 cm of jejunum, are not much different from the amounts of bicarbonate secreted by the pancreas in response to the same amounts of acid. The study confirmed earlier results that bicarbonate concentrations of up to 120 mmol/l may be required to account for the observed removal of acid and that the total calculated ionic composition of the net secreted fluid may be as high as 600 mmol/l, so that the secreted fluid is apparently hypertonic to extracellular fluid. It is concluded that the whole of the upper small intestine responds abnormally to acid. Whether the abnormal response of the small intestine to acid in patients with duodenal ulcer is secondary to the gastric hypersecretion and consequent excessive acidification of the small intestine is not known. It is also unclear whether the abnormal gastric secretory patterns in duodenal ulcer are secondary to the small intestinal dysfunction, because the abnormal intestine releases too little gastric inhibitor or an excessive amount of stimulation of the stomach, or whether both gastric and small intestinal dysfunction are common manifestations of an underlying pathophysiological state.

3387 24-HOUR CONTROL IN INTRAGASTRIC ACIDITY BY CIMETIDINE IN DUODENAL-ULCER PATIENTS.

(Eng.) Pounder, R. E.; Williams, J. G.; Milton-Thompson, G. J.; Misiewicz, J. J. (Central Middlesex Hosp., Park Royal, London NW10 7NS, England). *Lancet* 2(7944):1069-1072; 1975.

The effects of two dose regimens of cimetidine on 24-hr intragastric acidity were investigated in six untreated patients with duodenal ulcer and in four patients who had undergone truncal vagotomy and pyloroplasty for duodenal ulcer. The subjects received placebo capsules on the first day and cimetidine on the second day. Cimetidine at 0.8 g/day decreased 24-hr mean H^+ activity by 55% in the untreated patients, but 1.6 g/day decreased it by 67%; the difference was due to a greater nocturnal decrease in the high-dose group. Intragastric pH remained below 2.0 for much of the treatment day, but similar values were found in four post-vagotomy patients. It is concluded that cimetidine results in a decrease of intragastric acidity that is compatible with successful medical treatment of duodenal ulceration.

3388 GASTRIC ACID RESPONSES TO GRADED I.V. INFUSION OF PENTAGASTRIN AND HISTALOG IN PEPTIC ULCER PATIENTS BEFORE AND AFTER ANTRUM-BULB RESECTION.

(Eng.) Bergegardh, S.; Broman, G.; Knutson, U.; Palmer, L.; Olbe, L. (Sahlgren's Hosp., Gothenburg, Sweden). *Scand. J. Gastroenterol.* 11(4): 337-346; 1976.

The effect of antrum-bulb resection on the parietal cell responsiveness to pentagastrin and Histalog was studied in 46 men with duodenal ulcer and in 9 men with gastric ulcer by analyzing dose-response curves before and after antrum-bulb resection. Graded i.v. infusions of pentagastrin and Histalog (0.52, 1.62, 9.0, 29.8, 90.8, and 298 μg/hr pentagastrin; 0.9, 3, 9, 52, and 162 mg/hr Histalog) were infused, increasing the dose every 60 min. Single-day multiple-dose tests were performed. The sensitivity to the humoral stimuli, as determined by the calculated ED_{50}'s, was not significantly different by duodenal ulcer patients with moderate (DU_{mod}) or massive (DU_{mass}) observed hypersecretion or for gastric ulcer (GU) patients before operation; the median ED_{50}'s of pentagastrin were 6.2, 6.6, and 13.1 μg/hr in 18 DU_{mod}, 22 DU_{mass}, and 7 GU patients, resp., and the median ED_{50}'s of Histalog were 16.6, 25.3, and 17.1 mg/hr in 14 DU_{mod}, 10 DU_{mass}, and 6 GU patients, resp. Antrum-bulb resection significantly reduced basal acid secretion and maximal acid responses to the humoral stimuli (about 45% reduction) but did not significantly change the loss of gastric contents to the intestine or the sensitivity to the humoral stimuli (median ED_{50} of pentagastrin increased from 5.2 to 6.7 μg/hr in 14 patients, and median ED_{50} of Histalog increased from 16.0 to 20.8 mg/hr in 12 patients). The results suggest that the intact antrum-bulb region of the ulcer patient controls the capacity to secrete acid. It is concluded that antrum-bulb gastrin is an important trophic factor for the parietal cells in man.

3389 THE EFFECT OF LONG-TERM POSTOPERATIVE PENTAGASTRIN INFUSION ON THE MAXIMAL ACID RESPONSES TO PENTAGASTRIN IN PATIENTS SUBJECTED TO ANTRECTOMY.

(Eng.) Bergegardh, S.; Olbe, L. (Sahlgren's Hosp., S-413 45 Gothenburg, Sweden). *Scand. J. Gastroenterol.* 11(4):347-351; 1976.

The effect of postoperative pentagastrin infusion on post-antrectomy decrease of the maximal acid response to pentagastrin in duodenal ulcer patients was investigated. Six duodenal ulcer patients subjected to antrectomy were given a continuous i.v. infusion of pentagastrin in a dose just below ED_{50} (5.0, 1.0, 3.0, 2.5, 5.0, and 1.0 μg/hr, resp.) during the first week after operation. The peak acid output following stimulation with pentagastrin (PAO_G) was determined pre-operatively and 1 and 5 weeks postoperatively. PAO_G was determined pre-operatively and 1 week after antrectomy in a control group of 25 duodenal ulcer patients, and pre-operatively and 5 weeks after antrectomy in another control group of 19 duodenal ulcer patients. One week post-antrectomy, the PAO_G was significantly less reduced (23%) in the pentagastrin infusion group than in the control group (46%). The reductions of PAO_G, 5 weeks post-antrectomy, were not significantly different in the pentagastrin infusion group and the control group. The results indicate that the dysfunction of the parietal cells, reflected in a decreased capacity to secrete acid following antrectomy, can be partially reversed by continuous administration of pentagastrin in the immediate post-operative course. It is suggested that in addition to its ability to stimulate acid secretion, antral gastrin in man also has a trophic effect on the parietal cells. This is analogous with the postulated trophic effect of antral gastrin in rats.

3390 TREATMENT OF DUODENAL ULCER WITH A LONG-ACTING SYNTHETIC SECRETIN: A PILOT TRIAL.

(Eng.) Demling, L.; Domschke, W.; Domschke, S.; Belohlavek, D.; Baenkler, H. W.; Fruhmorgen, P.; Lingenberg, G.; Wunsch, E.; Jaeger, E. (Depts. Medicine, Immunology, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-852 Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 22(5):310-313; 1975.

The effects of 4 weeks of treatment with long-acting synthetic secretin (10 clinical U/kg/day, s.c.) were assessed clinically, endoscopically, immunologically, and by means of gastric and pancreatic secretory analyses in three men with duodenal ulcer. Reduction of epigastric pain was noted within a few days following the onset of secretin therapy. In all cases, duodenoscopy revealed complete healing of ulcers after a 2- to 3-week treatment period. Before therapy, cutaneous anaphylactoid reactions due to intradermal injections of secretin were elicited in each subject; skin reactions were found mitigated after 4 weeks of therapeutic secretin administration, thus suggesting some desensitization. Neither gastric acid secretion nor pancreatic bicarbonate production were substantially influenced by the 4-week course of secretin therapy; consequently, prevention of ulcer relapse is unlikely to be achieved with the conditions employed in this study. However, the results are promising, in that the duodenal ulcers showed complete healing after only 2-3 weeks of secretin administration.

3391 ENDOSCOPIC EVALUATION OF THE EFFECT OF ULCERONE AND PLACEBO ON DUODENAL ULCERS.

(Eng.) Moshal, M. G. (Dept. Medicine, Natal Univ., Durban, South Africa). *S. Afr. Med. J.* 50(21):801-802; 1976.

The therapeutic effects of 50 courses of tripotassium di citrato bismuthate (Ulcerone) and placebo administered to ambulant patients with duodenal ulcers were investigated in a double blind trial for 6 weeks. Duodenoscopy was used for initial assessment and to judge improvement. The ulcers of 20 out of 30 patients (67%) healed completely with Ulcerone treatment, while another 7 patients showed partial improvement. The ulcers of 4 out of 20 patients (20%) on placebo showed healing. The difference is highly significant (x^2=20.0; p<0.001). The time for abatement of symptoms on Ulcerone was 4.9 ± 2.3 days and on placebo it was 13.6 ± 5.7 days, which was significant (p<0.01). There were no significant age differences, but the duration of illness in the male patients on placebo, who achieved complete symptomatic and endoscopically visible healing, was significantly less than that of patients treated with Ulcerone (p<0.005). No side effects were observed with Ulcerone treatment. It is concluded that Ulcerone therapy is safe and effective for ambulant patients with duodenal ulcers.

3392 RECURRENCE OF GASTRIC ULCER AFTER SELECTIVE VAGOTOMY AND PYLOROPLASTY FOR CHRONIC UNCOMPLICATED GASTRIC ULCER: A 5-10 YEAR FOLLOW UP.

(Eng.) De Miguel, J. (Pasco de Zorrilla 30, Vailadolid, Spain). *Br. J. Surg.* 62(11):875-878; 1975.

The recurrence of gastric ulcer after selective vagotomy and pyloroplasty for chronic uncomplicated gastric ulcer was investigated in a 5-10 yr follow-up study of 67 patients. Recurrence of gastric ulcer was found in 13 of 73 patients (19.1%). It occurred equally as often after treatment of primary and secondary gastric ulcers and it was twice as common in women as in men. In three patients, recurrence was diagnosed within the first year after operation. In 10 patients, recurrence took place between 2-7 yr after operation, with an average of 5 yr. In each case, the ulcers appeared in the same place as the original ulcer. It is concluded that vagotomy and pyloroplasty cure benign gastric ulcer in about 80% of patients and should be taken into account in the choice of surgical treatment, especially in cases when a gastrectomy might be a risk. Because of the high recurrence rate, it is doubtful whether this operation should be considered as the treatment of choice for all cases of gastric ulcer.

3393 GASTRIC OUTLET OBSTRUCTION AFTER OMENTOPEXY FOR PERFORATED ACUTE AND CHRONIC DUODENAL ULCERATION.

(Eng.) Read, R. C.; Thompson, B. W. (Veterans Admin. Hosp., 300 East Roosevelt Road, Little Rock, AK 72206). *Am. J. Surg.* 130(6):682-687; 1975.

The incidence of gastric outlet obstruction after omentopexy for perforated acute and chronic duodenal ulceration was investigated in 187 patients. Seventeen patients received an immediate definitive procedure; none died. Nine (5%) of the remaining 170 patients who had omentopexy died 1-15 days postoperatively. A total of 121 patients were adequately followed; 39 had acute perforation and 82 had chronic perforation. Twenty-four chronic patients underwent definitive operation within 3 months without mortality. Of the 99 patients followed after omentopexy, 25% required re-operation within 12 months. In contrast, only 3 of the 39 with acute perforation required operation as compared with 21 of the 58 with chronic perforation. In the chronic group, obstruction was the main cause of early operation; 21% of the patients failed to empty their stomach immediately or soon after omentopexy and half as many had pain or bled severely within 12 months; they also required re-operation. Overall, 57% of the 99 patients required a definitive operation 1-24 yr later; only 10 of the 39 patients in the acute group required definitive operation as compared with 45 of the 58 patients in the chronic group. Outlet obstruction of the stomach was the main indication for definitive surgery in 26 of the 55 reoperations. It is recommended that patients with chronic perforation should undergo immediate vagotomy and a drainage procedure rather than omentopexy.

3429 ADJUSTMENT OF ALKALINE pH IN AN ISOLATED JEJUNAL LOOP IN RELATION TO THE RATE OF PERFUSION.

(Fre.) Ardisson, J. L.; Dolisi, C.; Ozon, C. (Faculte de Medecine de Nice, avenue de Vallombrose, 06100 Nice, France). *C. R. Soc. Biol. (Paris)* 168(10/12):1382-1388; 1974.

The Thiry-Vella jejunal ansa (50 cm) of a dog was perfused with 6 ml/min and 3 ml/min solutions of NaCl-glucose at various pH levels (7.3-10.0) to determine the adjustment rate of alkaline pH values. Results indicate that the jejunal ansa adjusted quickly to a pH of about 7.6 and that solutions with a pH above 10.0 caused serious absorption disorders. The rate of perfusion influenced the adjustment; for 6 ml/min, the correlation between the pH at entry and the pH at exit persisted, implying that the adjustment is not completely finished upon exit. This correlation was not found with the 3 ml/min perfusion.

3430 ARTERIOMESENTERIC DUODENAL COMPRESSION SYNDROME: COMPARISON OF METHODS OF TREATMENT.

(Eng.) Appel, M. F.; Bentlif, P. S.; Dickson, J. H. (6624 Fannin St., Houston, TX 77025). *South. Med. J.* 69(3):340-342; 1976.

The clinical features and treatment methods for a group of 80 patients with arteriomesenteric duodenal compression syndrome is reviewed. Forty-eight patients were from a VA hospital. Vomiting was the most common symptom, present in 73% of patients in the accumulated series, followed by pain in 42%, and distension in 21% of the patients. Typical roentgenographic findings included duodenal, and sometimes gastric distension, which was sometimes accompanied by reverse peristalsis in the duodenum. Complete or nearly complete obstruction was seen in the transverse portion of the duodenum. These findings were present in 100% of the VA series and in 84% of the accumulated series. The incidence of ulcer disease and alcoholism with pancreatitis was much greater in the VA series, while in the accumulated series, the associations with asthenia and scoliosis were most common. The success and failure rates were fairly similar between medically (17) and surgically (15) managed patients in the VA series. In the accumulated series, the surgical results were superior to the nonsurgical results. Of the 27 patients initially treated medically, 9 recovered and 18 had early failure. Of the 102 treated surgically, only 3 required a second procedure for ultimate cure. The two most commonly performed operations were section of the ligament of Treitz and duodenojejunostomy. The greatest success for both groups occurred after duodenojejunostomy. It is concluded that duodenojejunostomy is a safe and effective operation for the majority of patients who require surgery for arteriomesenteric duodenal compression syndrome.

3431 PRIMARY INTESTINAL LYMPHOMA AND ITS RELATION TO ALPHA HEAVY CHAIN DISEASE.

(Eng.) Ramot, B.; Hulu, N. (Chaim Sheba Medical Center, Tel-Hashomer, Israel). *Br. J. Cancer* 31(Suppl. 2):343-349; 1975.

Clinical manifestations and the course of intestinal lymphoma, as well as its relation to α-heavy chain disease, are described. Two cases occurring in Arab men are presented. Both presented with severe malabsorption and αI type heavy chain disease in the serum. In one case, x-ray of the intestine showed an abnormal mucosal pattern with signs of pressure suggesting intestinal lymphoma. In the other case, only a malabsorption pattern was seen. In both cases, a diagnosis of intestinal lymphoma was reached. The first patient received tetracycline (1 g/day) and later intermittent Alkeran (melphalan) later and the immunoglobulin G level diminished. The second patient responded to tetracycline therapy to the point of possible recovery, casting doubt on the original diagnosis of a malignant condition. The α-heavy chain diminished from 2,600 mg/100 ml to 550 mg/100 ml in this second patient. Thus, α-heavy chain disease may be regarded as an immune response of the gut to a noxious agent, followed by a clonal evolution of a functionally abnormal plasma cell. However, when severe monotonous uniform cell infiltration with destruction of the glands is present, a malignant process is suggested. Observations have indicated that the Arab population is exposed to repeated infections. However, studies of immunoglobulin levels to determine predisposing factors were discouraging.

3432 CONGENITAL CHLORIDORRHOEA: A QUESTION OF REVERSED BRUSH BORDER TRANSPORT PROCESSES AND VARYING JUNCTIONAL TIGHTNESS.

(Eng.) Rask-Madsen, J.; Kamper, J.; Oddsson, E.; Krag, E. (Herlev Hosp., DK-2730 Copenhagen/Herlev, Denmark). *Scand. J. Gastroenterol.* 11(4):377-383; 1976.

The effect of glycochenodeoxycholic acid (GCDC) on transepithelial ionic fluxes and the transmural potential difference (PD) in the perfused small and large intestine were studied in an 8-month-old boy with congenital chloridorrhea. Na, K, and Cl, as well as water, were secreted in the ileum, and HCO_3 was absorbed. The lumen was 91 mV negative to blood. Only Cl was transported against both electrical and chemical gradients, but discrepancies between observed and predicted Na flux ratios suggested the presence of a Na-absorbing mechanism as well. Mucosa was impermeable to Cl from the lumen side. GCDC, 2.5 mM, mediated Na and water absorption and abolished any transport of Cl. The PD was -95 mV. In the colon, a similar pattern was observed, and mucosa to serosa fluxes of Cl were abnormally low. Rectal PD was -116 mV. GCDC made the epithelium more absorptive in function, but contrary to ileum, the effect was due to an increase of Na and Cl fluxes from mucosa to serosa. The patient was at that time in severe electrolyte imbalance. He was reinvestigated 3 months later and was found to be in good clinical condition with normal serum electrolytes. Net transfer of electrolytes and water and bidirectional fluxes of Cl and K were unchanged while bidirectional Na fluxes increased considerably and PD decreased to -18 mV. Rectal PD was -45 mV. In the jejunum, water and electrolyte transport were normal, and PD was -3 mV. It is tentatively concluded that the abnormal transport in ileum is due to an inversion of the brush border transport processes, which also satisfies the paradoxical effects of GCDC. Na and Cl seem to migrate through separate pathways. A varying degree of junctional tightness, which is almost completely cationic, may be responsible for the functional differences observed in response to improvement of the general electrolyte status.

3433 DECREASED TRYPSIN AND BILE ACIDS IN ILEAL FISTULA DRAINAGE DURING THE ADMINISTRATION OF A CHEMICALLY DEFINED LIQUID ELEMENTAL DIET.

(Eng.) Hill, G. L.; Mair, W. S. J.; Edwards, J. P.; Goligher, J. C. (Univ. Dept. Surgery, General Infirmary, Leeds, England). *Br. J. Surg.* 63(2):133-136; 1976.

Ten patients with a well established ileostomy were studied, and alterations in ileostomy content of trypsin and bile acids were measured during the ingestion of an elemental diet. After a 4-day control study, the patients were given an elemental diet as the sole nutritional source for a 10-day period. For the last 3 days of the study, an additional 2 l of water were consumed with the elemental diet. The mean daily fecal output for the group during the control period was 578 ± 300 ml, and during administration of the elemental diet the fistula output fell to 418 ± 190 ml ($p<0.02$); there was also a decrease in the concentration of sodium in the ileal fluid (104.7 ± 22 mEq/l to 80.2 ± 25 mEq/l, $p<0.01$). For the group as a whole, there was a decrease in the concentration of trypsin (0.671 IU/ml to 0.554 IU/ml, $p<0.025$) and bile acids (0.911 mmol/ml to 0.662 mmol/ml, $p<0.005$) in the ileal excreta. Although the concentration of amylase in the ileal fluid rose, the total output was not altered. Oral administration of an additional 2 l of water did not alter the concentration of trypsin or bile acids in the ileal fluid. It is concluded that elemental diet ingestion produces changes in ileal fistula output that are beneficial to the patient with an enterocutaneous fistula. Output from the fistula of fluid and electrolyte, and the corrosive nature of the discharge are both reduced.

3434 EXPERIENCE WITH 26 RESERVOIR ILEOSTOMIES.

(Eng.) Goligher, J. C.; Lintott, D. (General Infirmary, Leeds, England). *Br. J. Surg.* 62(11):893-900; 1975.

Experience gained in establishing reservoir ileostomies in 26 patients is presented. In 13 cases, the operation represented a conversion from a previous conventional ileostomy, and in the other 13 cases, the reservoir ileostomy was part of the primary colectomy or proctocolectomy. In two or three cases, the original pathological state was Crohn's disease; in the rest, it was ulcerative colitis. In eight patients, recovery was seriously impeded by complications related to the reservoir technique. Of the 23 patients who left the hospital with a reservoir ileostomy, 8 had a reservoir without nipple valves and 15 had reservoirs with nipple valves. Nine of the patients with nipple valves were fully continent and had no need for an external ileostomy appliance; these nine operations were considered completely successful. The best chance for obtaining a truly continent reservoir requires the creation of an efficient valve in the exit conduit. In patients who suffered extrusion of the valve, it was sometimes possible to effect a reconstruction of the valve at a subsequent operation; this yielded good results or at least some improvement. In cases where refashioning was not attempted, and intubation was difficult or impossible, the stoma could be managed like a conventional ileostomy, allowing ileal contents to drain incontinently into an ileostomy bag. In patients with an intact functioning valve and periodic obstruction to the passage of the tube, together with complete retention in the reservoir, a further surgical approach to the valve to alter its axis was occasionally beneficial. There was no operative mortality in this series.

3435 ARTHRITIS ASSOCIATED WITH INTESTINAL-BYPASS PROCEDURE FOR MORBID OBESITY: COMPLEMENT ACTIVATION AND CHARACTERIZATION OF CIRCULATING CRYOPROTEINS.

(Eng.) Wands, J. R.; LaMont, J. T.; Mann, E.; Isselbacher, K. J. (Massachusetts General Hosp., Boston, MA 02114). *N. Engl. J. Med.* 294(3):121-124; 1976.

Five patients were studied after intestinal bypass operations for morbid obesity to determine if the arthritis observed in three of these patients was associated with circulating cryoproteins. The case reports of the arthritic patients are presented. Only serum from the three patients with acute arthritis contained cryoprotein complexes. The complexes comprised immunoglobulin (Ig) G, IgM, IgA, complement components C_3, C_4, C_5, and IgG antibody against *Escherichia coli* and *Bacillus fragilis*. The C_3-activator fragment of the properdin complex was identified in fresh serum samples obtained from two of the three patients with circulating cryoprotein complexes and arthritis. These observations suggest that systemically absorbed intestinal bacterial antigens may lead to (or contribute to) the formation of circulating cryoprotein complexes. Circulating cryoprotein complexes activate both the classical and alternate complement pathways and may be important in the pathogenesis of the arthritis associated with the intestinal bypass procedure for morbid obesity.

3436 IMMUNOLOGICAL FUNCTION IN PATIENTS OPERATED ON WITH SMALL INTESTINAL SHUNTS FOR MORBID OBESITY.

(Eng.) Hallberg, D.; Nilsson, B. S.; Backman, L. (Karolinska Hosp., S-104 01, Stockholm 60, Sweden). *Scand. J. Gastroenterol.* 11(1):41-48; 1976.

Immunological functions were studied in obese patients before and at 4, 8, and 12 months after ileojejunal bypass operation. Four patients underwent a jejuno-ileostomy end-to-side operation; others underwent a jejuno-ileostomy end-to-end with an ileo-coecostomy of the blind loop. No serious postoperative complications occurred. Weight loss was about 40 kg/patient 12 months after operation. In all but one case, there was an increased reactivity to PPD tuberculin after operation, rising from a preoperative level of 13.2 to 33.2 mm diameter at 12 months after operation. Immediate reactions to *Candida albi-*

cans were noted in 2/11 patients before operation and in 8/8 patients at 12 months after operation. No essential changes were noted in WBC and differential counts during the study period, nor were there changes in immunoglobulin concentrations. For the group as a whole, there was no significant change in sheep erythrocyte-binding lymphocytes. A statistically insignificant increase occurred in the lymphocyte reactivity to phytohemagglutinin. Lymphocyte reactivity to PPD and tetanus toxoid increased only slightly. Thus, within a year after operation, an increased immunological reactivity against two unrelated antigens, as measured by skin tests, was noted. This reactivity seems to be of both B cell type (immediate reactions to *Candida*) and T cell type, as evidenced by delayed reactions. At present, there is no explanation of the findings.

3437 POST-PRANDIAL CHANGES IN pH AND ELECTROLYTE CONCENTRATION, IN THE UPPER JEJUNUM AFTER TRUNCAL VAGOTOMY AND DRAINAGE IN MAN. (Eng.) Temple, J. G.; Birch, A.; Shields, R. (Manchester Univ., Dept. Surgery, Salford, Lancs, England). *Gut* 16(12):961-965; 1975.

Changes in pH and electrolyte concentrations in the lumen of the upper small bowel were studied in 21 patients after truncal vagotomy and drainage and in a control group of subjects who had no gastric operation. Generally, the jejunal pH of post-vagotomy patients was related to the results of the insulin test. In insulin-negative patients, the jejunal content was more alkaline throughout the test than in either insulin-positive or control subjects. There was no relation between jejunal pH and post-vagotomy diarrhea. The jejunal sodium concentration pattern in post-vagotomy subjects was different from that in controls. There was a rapidly increasing sodium concentration throughout the first 60 min of the test. At 120 and 150 min, sodium concentration in the incomplete vagotomy group was similar to controls. However, patients with a complete vagotomy maintained a higher sodium concentration than either the incomplete vagotomy or the control subjects throughout the test. No relation was found between post-vagotomy diarrhea and jejunal sodium concentration. All post-vagotomy patients showed a steady fall in potassium concentration, but the value at 60 min in both insulin-negative and insulin-positive patients was significantly lower than that in controls regardless of the presence or absence of diarrhea. During the first 30 min of the test, both the complete and incomplete vagotomy patients showed chloride concentrations significantly lower than controls. After 60 min, the incomplete vagotomy patients had potassium levels that were similar to controls while those with complete vagotomies continued to demonstrate lowered potassium lelvels. Chloride concentrations of post-vagotomy subjects showed no variations between those who were insulin-negative or insulin-postive. It is concluded that after truncal vagotomy and drainage, the pH and concentrations of sodium and potassium in the upper small bowel are related chiefly to the completeness of vagal section. Post-vagotomy diarrhea has no particular association with these findings.

Malabsorption

3467 SPECIFICITY OF ULTRASTRUCTURAL CHANGES OF SMALL INTESTINAL EPITHELIUM IN EARLY CHILDHOOD. (Eng.) Araya, M.; Walker-Smith, J. A. (Royal Alexandra Hosp. Children, Camperdown, N.S.W., 2050, Australia). *Arch. Dis. Child.* 50(11):844-855; 1975.

Ultrastructure of the small intestinal mucosa was studied in 30 consecutive small intestinal biopsies taken from 30 children with probable celiac disease (14) or nonspecific mucosal damage (16) due to chronic intermittent diarrhea from various causes. Findings were compared to normal small intestinal mucosa. The most common findings in celiac biopsies included an abnormal brush border, increased number of free ribosomes, rich rough endoplasmic reticulum, poorly developed smooth endoplasmic reticulum, large Golgi complexes, and thickened basal lamina. These changes are suggestive of abnormal cellular metabolism. However, they were also observed in children with a variety of clinical conditions and could not be specifically related to celiac disease. In small children, different causes leading to different degrees of abnormal small intestinal mucosa produce nonspecific changes of the cellular ultrastructure, which cannot be related to the degree of abnormality observed at the light microscopic level.

3468 HYPERSENSITIVITY TO COW'S MILK: NEW STUDY OF 33 CASES. (Fre.) Despres, P.; Gendrel, D.; Plainfosse, B.; Chirazi, S.; Seringe, P. (Hopital des Enfants Malades, 75730 Paris Cedex 15, France). *Ann. Pediatr.* 21(5):375-384; 1975.

Case reports of 33 nursing infants who developed intolerance to cow's milk are presented. Similar hypersensitivity occurred in close family members in 14 cases, and 7 cases had a family history of allergy (asthma, eczema, urticaria, etc.). Symptoms appeared when infants were less than 3 weeks old in 24 cases and before 3 months in the other cases. Diarrhea occurred in all 33 infants and concomitant dehydration was the reason for hospitalization in 26 of the cases. Additional symptoms included vomiting, severe shock, anorexia, and excessive thirst. Eczematous erythema was observed in 12 cases, usually on the face, and 22 infants were anemic. Examination of stools usually revealed a pH greater than 7, which distinguished the diarrhea from that of sugar intolerance. Sugar or blood was frequently present in the stools, and gram positive bacteria were predominant. Mild steatorrhea was often observed after prolonged periods. Indications of malabsorption included hyperglycemia, after oral glucose or xylose, and hypoproteinemia. Barium x-rays of the small intestine revealed hypersecretion, jejunal dilation, and thickening of the mucosa. Utilizing lactoglobulin and lactoalbumin as antigens, the lymphoblast transformation test proved positive in 17 of the 33 cases. Infants were treated with i.v. diets or with carrot soup until their digestive systems became normal. Synthetic, reconstituted milk or milk from humans or horses was substituted for cow's milk. Hypersensitivity to cow's milk disappeared spontaneously, most often between the ages of 10 months and 2.5 yr.

3469 DEFICIENCY OF SECRETORY Ig-A AND INTESTINAL MALABSORPTION. (Eng.) Krakauer, R.; Zinneman, H. H.; Hong, R. (Minneapolis Veterans Admin. Hosp., Minneapolis, MN). *Am. J. Gastroenterol.* 64(4):319-323; 1975.

Deficiency in secretory immunoglobulin (Ig) A and near abscence of secretory component (S.C.) in the jejunal contents of a 52-yr-old uremic man with diarrhea and malabsorption syndrome were investigated. Secretory IgA was present only in trace amounts in the jejunal contents and parotid secretions, whereas normal subjects showed secretory IgA in concentrations of 70-340 mg/100 ml. Serum concentrations of IgA were normal. Only traces of S.C. were found in the jejunal aspirate. The jejunal aspirate yielded bacterial growth of 10^8 colonies of *Streptococci*/mm^3, which were sensitive to cephalothin, tetracycline, chloramphenicol, and lincomycin. When the patient was given human colostrum (20-30 ml/day), his diarrhea disappeared within a week. By 6 weeks, the malabsorption parameters had improved; serum carotene concentration rose from 51 to 73 µg/100 ml and the 2-hr calcium absorption rose to 1.18%/1. At this point, the patient refused further colostrum, and weakness and diarrhea reappeared. The case poses questions concerning the etiology of a malabsorption syndrome appearing during chronic renal insufficiency. The reversal of diarrhea and malabsorption following p.o. administration of human colostrum may have been due to the relatively modest amount of secretory IgA present in the colostrum. Lactoferrin may also have been involved, as enterococci may have been affected by the iron-binding activity of lactoferrin.

3470 THE ABSORPTION OF ANTIBIOTICS IN ADULT PATIENTS WITH COELIAC DISEASE. (Eng.)

Parsons, R. L.; Hossack, G.; Paddock, G. (Guy's Hosp. Medical Sch., St. Thomas' St., London SE1 9RT, England). *J. ANtimicrobiol. Chemother.* 1(1):39-50; 1975.

Patterns of antibiotic absorption were studied in groups of normal subjects and adults with celiac disease. Drugs studied included amoxycillin, ampicillin, cephalexin, clindamycin, erythromycin ethyl succinate, erythromycin stearate, sodium fusidate, lincomycin, pivampicillin, rifampicin, sulfamethoxoazole, and trimethoprim. Four different patterns of antibiotic absorption were noted in celiac patients. A significant increase in the mean plasma levels 2 hr after dosing in celiacs compared with normal subjects was noted for trimethoprim (1.58 versus 1.18 μg/ml), sulfamethoxazole (48.35 versus 39.67 μg/ml), fucidin (24.12 versus 14.45 μg/ml), cephalexin (10.31 versus 6.90 μg/ml), and clindamycin (2.57 versus 2.10 μg/ml). The absorption of amoxycillin and pivampicillin was definitely impaired. Peak absorption of rifampicin was delayed from 4.99 μg/ml at 1 hr for normal controls to 4.82 2 hr for celiac patients. Ampicillin, erythromycin ethyl succinate and stearate, and lincomycin absorption was not significantly different in celiacs as compared with normal subjects. Conventional factors said to control drug absorption, such as lipid solubility, molecular weight, or pK_a did not account for these findings. The etiology of changes in antibiotic absorption in celiac disease is probably multifactorial, including alterations in the rate of gastric emptying, changes in intestinal motility, alterations in the concentration gradient across the intestinal lipid membrane, and increased permeability across the damaged mucosa. Impaired absorption of drugs requiring hydrolysis to their active constituents is probably related to deficiencies of enzymes such as esterase, which occur in celiac disease.

3471 CELL-MEDIATED IMMUNITY TO GLUTEN FRACTION III IN ADULT COELIAC DISEASE. (Eng.)

Holmes, G. K. T.; Asquith, P.; Cooke, W. T. (Dept. Experimental Pathology, Univ. Birmingham, England). *Clin. Exp. Immunol.* 24(2):259-265; 1976.

The *in vitro* response to 2 and 4 mg of gluten fraction III of peripheral blood lymphocytes from 27 healthy control subjects, 21 celiac patients on a gluten free diet, and 14 patients on a normal diet was investigated. The cell-mediated response to gluten was determined by measuring the degree of stimulation of lymphocytes cultured in the presence of antigen and tritiated thymidine (0.5 μCi, 150 mCi/mM). There were significant increases in the mean ratios of response for lymphocytes from gluten free celiacs as compared with healthy controls, after 4, 5, and 6 days of culture. There was no significant difference between the mean response of celiacs on a normal diet and controls at 2 mg, although with 4 mg gluten the difference was significant ($p<0.05$) on days four and five of culture. For each day of harvest, a greater percentage of gluten free celiacs had increased ratios compared with those on a normal diet, for both 2 and 4 mg gluten. The percentage of patients on a gluten free diet with at least one abnormal result on day 4, 5, or 6, irrespective of the amount of gluten fraction III used in the cultures, was 52% (11/21) compared with 29% (4/14) for normal diet subjects. When three additional patients were changed from a normal to a gluten free diet, the ratios of response for their lymphocytes increased. The results suggest that certain celiacs may exhibit a delayed hypersensitivity reaction to gluten.

3472 ELECTROGENIC GLUCOSE ABSORPTION IN UNTREATED AND TREATED COELIAC DISEASE. (Eng.)

Read, N. W.; Levin, R. J.; Holdsworth, C. D. (Royal Infirmary, Sheffield, England). *Gut* 17(2):444-449; 1976.

Changes in electrogenic glucose absorption was investigated in patients with active and treated celiac disease and in healthy volunteers. The operational kinetic parameters of "Apparent KM" and potential difference (PD) max were estimated using a method for measuring changes in transmural PD across the human jejunum *in vivo*. The transfer PD generated by 10 mM glucose was much higher in patients with untreated celiac disease ($p<0.0001$). At 20 mM ($p<0.005$) and at 50 mM ($p<0.05$), the differences in PD became less significant and at 100 mM, the transfer PD's were virtually identical. Both the Apparent KM (17 ± 2 mM) and the PD max (8.6 ± 0.7 mV) in nine patients with untreated celiac disease were significantly lower ($p<0.005$) than in the control group (Apparent KM, 74 ± 5 mM; PD max, 12.8 ± 0.9 mV). Treatment of five celiac patients with gluten withdrawal for less than 3 months increased significantly the values of both the Apparent Km (35 ± 6 mM) and the PD max (11.4 ± 1.2 mV). Treatment of five patients for more than 6 months caused a further increase in the values of both kinetic parameters (Apparent KM, 108 ± 13 mM, $p<0.005$; PD max, 15.6 ± 2.7 mV, $p>0.05$) to levels which exceeded those in healthy subjects. The results indicate that the operational kinetic parameters of electrogenic glucose absorption are greatly affected by celiac disease.

3473 JEJUNAL PERFUSION OF SIMPLE AND CONJUGATED FOLATES IN TROPICAL SPRUE. (Eng.)

Corcino, J. J.; Reisenauer, A. M.; Halsted, C. H. (Univ. Puerto Rico Sch. Medicine, San Juan, PR 00936). *J. Clin. Invest.* 58(2):298-305; 1976.

Absorption of labeled simple 3',5',9'-^{3}H pteroylmonoglutamate ([^{3}H]PG-1) and conjugated pteroyl-μ[^{14}C]glutamyl-γ-hexaglutamate ([^{14}C]PG-7) folates was assessed in six patients with tropical sprue, before and after 6 months of treatment, utilizing jejunal perfusion and urinary recovery techniques. Degradation products of [^{14}C]PG-7 produced during perfusion were identified by DEAE-cellulose column chromatography. Jejunal mucosal activities of folate conjugase, lactase, sucrase, and maltase were measured in every patient. Malabsorption of both [^{3}H]-PG-1 and [^{14}C]PG-7 was found in all patients prior to treatment; significant improvement was observed after therapy. The urinary excretion of ^3H and ^{14}C paralleled the luminal disappearance of both isotopes. The chromatographic patterns of intraluminal degradation products of [^{14}C]PG-7 obtained during perfusion did not differ from those previously found in normal subjects and were similar in studies performed before and after treatment. The activity of folate conjugase was increased in the mucosa of the untreated patients when compared to the post-treatment levels, while the activities of mucosal lactase, sucrase, and maltase were originally low and increased significantly ($p<0.01$, $p<0.01$, $p<0.005$ for lactase, sucrase, and maltase, resp.) after therapy. It is suggested that folate conjugase originates at a different mucosal locus than the brush border disaccharidases and that folate conjugase is an intracellular enzyme. The results demonstrate unequivocal malabsorption of both simple and conjugated folates in tropical sprue. In tropical sprue, folate malabsorption is the reflection of impaired folate transport and not of impaired hydrolysis.

3474 CHRONIC IDIOPATHIC HYPERPHOSPHATASIA: A CASE WITH MALABSORPTION SYNDROME. (Ita.) Duillo, M. T.; Pelizza, A.; Caramia, G. (Istituto di Puericultura "L. Gaslini" dell'Universita di Genova, Genova, Italy). *Minerva Pediatr.* 27(27): 1465-1477; 1975.

LARGE INTESTINE

3479 AN OPTICAL AND ULTRASTRUCTURAL STUDY OF THE LOCALIZATION OF CARCINOEMBRYONIC ANTIGEN (CEA) IN NORMAL AND CANCEROUS HUMAN RECTOCOLONIC MUCOSA. (Eng.) Huitric, E.; Laumonier, R.; Burtin, P.; Von Kleist, S.; Chavanel, G.; (Centre Regional de Lutte Contre le Cancer, 76038 Rouen, France). *Lab. Invest.* 34(1):97-107; 1976.

An immunoenzymologic method using peroxidase-labeled antibodies was applied on frozen sections, on Araldite-embedded sections, and on isolated cell preparations of normal rectocolonic mucosa and of rectal and colonic cancers (adenocarcinomas and one villous tumor) for the localization of carcinoembryonic antigen (CEA). CEA appeared intimately associated with the external coating of the striated border of the normal columnar cell and with the external coating of the apical pole of the cancerous cell. CEA was also found as an intracellular component of the normal epithelial cell of the rectocolonic mucosa, mainly the goblet cell. In tumors, it appeared as an intracellular component of the mucous-secreting cell. Its presence in the cell coat and interior of the cell correlated with the degree of differentiation of the cells, whether cancerous or not. Progressive accumulation of CEA in the normal colonic epithelial cell was observed in cells undergoing maturation, and its release by the mature goblet cell was also observed. These results confirm that CEA is a normal glycoprotein constituent of the epithelial cell of the human adult rectocolonic mucosa, synthesized and discharged by this cell. The previously reported difference in CEA content between the cancerous and the normal rectocolonic mucosa appears to be quantitative and not qualitative.

3480 THE EVOLUTION OF CANCER OF THE COLON AND RECTUM. (Eng.) Muto, T.; Bussey, H. J. R.; Morson, B. C. (St. Mark's Hosp., City Road, London, EC1V 2PS, England). *Cancer* 36(6):2251-2270; 1975.

The malignant potential of adenomatous polyps and villous adenomas of the colon and rectum was analyzed. The material included 2,231 polyps and 275 cancers, which were wholly or partially macroscopically benign. The presence of contiguous benign and malignant tissue suggested that the cancer arose from a previously benign tumor. About 60% of the polyps were less than 1 cm in diameter, 20-25% were 1-2 cm and only 15-20% were over 2 cm in diameter. As polyps grew, cancer risk increased. Of the benign tumors, 75% were classified as adenomatous polyps, and only 10% were classified as villous adenomas. An intermediate or tubulo-villous architecture was noted in 15%. The malignant potential varied in relation to size and histological type. The very common adenomatous polyp under 1 cm in diameter had a 1% malignant potential, while the rare small villous tumor had a malignancy rate of 9.5%. The rare intermediate histological type had a 4% malignant potential. In tumors between 1-2 cm in diameter, the malignancy rate did not differ significantly for the three histological types, being 10.2%, 10.3%, and 7.4%, resp. Tumors over 2 cm in diameter had malignant potentials of 34.7%, 52.9%, and 45.8%, resp., for the three types. About 70% of all polyps showed mild atypia and had a malignant rate of 5.7%. Severe atypia occurred in 10% of the polyps, with 34.5% containing invasive cancer. Polyps graded as moderate atypic accounted for 20% of the whole and of these, 18.0% had invasive cancer. A gradual transition from benign to malignant situations, passing through stages of increasingly severe epithelial atypia before becoming invasive was suggested. The evolution of cancer from isolated adenomatous polyps took 10-15 yr. Cancer risk increased with the number of adenomas. Of the 1,199 patients with only one adenoma, 263 (21.9%) had cancer; of the 66 with three adenomas, 30 (45.5%) had cancer; of the 12 with five adenomas, 9 (75%) had cancer; and of the 16 with six or more adenomas, 11 (68.8%) had cancer. While evidence indicates that removal of polyps can be equated with prevention of cancer, this cannot be accurately measured at present.

3481 END RESULTS OF RADIATION THERAPY ALONE AND COMBINATION WITH 5-FLUOROURACIL IN COLORECTAL CANCERS.

(Eng.) Vongtama, V.; Douglass, H. O.; Moore, R. H.; Holyoke, E. D.; Webster, J. H. (Buffalo General Hosp., 100 High St., Buffalo, NY 14203). *Cancer* 36(6):2020-2025; 1975.

The clinicopathologic behavior of 148 patients with recurrent (95) and inoperable (53) colorectal cancers and their responses to and survival rates following irradiation alone or combined with 5-fluorouracil (5-FU) were investigated. Uninterrupted radiotherapy (1138 or 1250 RET) was applied in 118 cases and split course technique was used in 30 cases (1591 RET). Eleven patients received combined radiotherapy and surgery. Seventy-eight patients received a combination of 15 mg 5-FU and irradiation. Of the patients treated with split course technique, 87% had good to excellent responses, while only 70% of the patients with uninterrupted radiotherapy had the same response. The cumulative survival of all 148 patients was 20.6% at 24 months and 9.6% at 5 yr. Survival was more favorable in the patients with distant metastasis to lumbar spines and pelvic disease ($p<0.01$), and significantly higher survival was found for patients with pelvic disease in comparison to patients with only distant metastasis ($p<0.01$). A significantly higher survival rate ($p<0.05$) was found for the split course technique in comparison to uninterrupted radiotherapy. There was a significantly higher survival rate for patients treated with 5-FU in the inoperable group ($p<0.01$). It is concluded that the split course technique yields in comparison higher survival rates and longer palliation than does uninterrupted radiotherapy. Combined radiotherapy and 5-FU causes significantly higher survival rates in patients with inoperable colorectal cancers.

3482 ADJUVANT IMMUNOTHERAPY AND CHEMOTHERAPY IN COLORECTAL CANCER OF THE DUKES' C CLASSIFICATION: PRELIMINARY CLINICAL RESULTS.

(Eng.) Mavligit, G. M.; Gutterman, J. U.; Burgess, M. A.; Khankhanian, N.; Seibert, G. B.; Speer, J. F.; Reed, R. C.; Jubert, A. V.; Martin, R. C.; McBride, C. M.; Copeland, E. M.; Gehan, E. A.; Hersh, E. M. (M.D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX 77025). *Cancer* 36(6):2421-2427; 1975.

Fifty-eight patients with Dukes' C classification of carcinoma of the large bowel were placed on adjuvant immuno- or chemoimmunotherapy with Bacillus calmette guerin (BCG) or combination of 5-fluorouracil (5-FU) plus BCG following primary and definitive surgery, and were followed for up to 21 months. Of 26 patients receiving BCG, alone, by scarification (6×10^8 viable organisms/week for 3 months, and then every other week thereafter), 5 had relapse with 75% of freedom from disease estimated at 15.1 months compared with 10.1 months in 73 selected histor ical controls who had surgery alone ($p=0.12$). The survival of all patients receiving BCG alone has not yet reached the 75 percentile, and the difference from controls is currently estimated at the 18% level. The combination of 5-FU (100 or 150 mg/m^2, 4 x daily for 5 days and repeated every 4 weeks) plus BCG (studied in 32 patients) appears to more effectively protect against tumor recurrence (75 percentile not yet reached compared with control, ($p=0.08$). The survival of patients on 5-FU plus BCG also appears to be improved ($p=0.09$). No patients have expired as compared to a 75 percentile survival of 16.6 months in the control. Serial determination of plasma carcinoembryonic antigen (CEA) was crucial in the clinical follow-up of these patients. Frequent CEA determinations led to early detection of clinical relapse. In the absence of any other unequivocal signs of relapse, a persistent and progressive elevation of CEA suggests tumor recurrence with a high degree of probability in patients with past history of cancer of the large bowel.

3483 FECAL BACTERIOLOGY OF COLONIC POLYP PATIENTS AND CONTROL PATIENTS.

(Eng.) Finegold, S. M.; Flora, D. J.; Attebery, H. R.; Sutter, V. L. (Wadsworth Hosp. Center, Los Angeles, CA 90024). *Cancer Res.* 35(11):3407-3417; 1975.

The fecal bacterial flora in feces from 25 subjects with colonic polyps (multiple adenomatous, large single, or single with atypia) and from 25 matched control subjects were investigated by detailed quantitative aerobic and anaerobic techniques, using a large battery of culture media under several atmospheric conditions. Over 55% of organisms detected on microscopic count were recovered anaerobically. When extremely oxygen sensitive anaerobes were present, they accounted for about 20% of the anaerobic flora. Although certain differences between the polyp and control patients were statistically significant, a few so called statistically significant differences occurred by chance alone. While the same genera (*Streptococcus*, *Eubacterium*, *Bifidobacterium*, and *Peptostreptococcus*) were often noted in this study, and in an earlier comparison of Japanese Americans on a Japanese diet versus those on a western diet, the species involved were always different. It is concluded that additional studies are necessary to investigate the interrelation between diet, intestinal bacteria, and bowel cancer.

3484 ARYLSULFATASE B IN COLORECTAL CANCER. (Eng.) Morgan, L. R., Jr.; Samuels, M. S.; Thomas, W.; Krementz, E. T.; Meeker, W. (Louisiana State Univ. Medical Center, 1542 Tulane Ave., New Orleans, LA 70112). *Cancer* 36(6):2337-2345; 1975.

Arylsulfatase B activity was determined in 24-hr urine samples and/or tissues from 243 patients with colorectal cancer and it was compared to that in 20 normal subjects. Elevated activity of the enzyme [9.8 ± 2.4 to 28.9 ± 9.2 mg of 5-nitrocatechol liberated/24-hr specimen/hr; these values were significantly different ($p<0.05$) from levels in normal urine] was observed in 172 patients. Employing Dukes' modified classification of colorectal cancer (type A, confined to the mucosa and submucosa; B, invasion through the muscularis with nodal metastasis; C, metastasis to regional lymph nodes; and D, metastasis to distant organs), urine arylsulfatase B activity was elevated in Dukes' A lesions (12%), Dukes' B lesions (55%), Dukes' C lesions (80%), and Dukes' D lesions (82%). Arylsulfatase B activity in urine, when elevated, may be used to follow response to therapy since in those patients with elevated urine arylsulfatase B values who subsequently responded to therapy, the enzyme values became or approached normal. Urine arylsulfatase B activity also correlated with plasma carcinoembryonal antigen (CEA) as a diagnostic indicator of colorectal cancer in 33 of 46 patients. In contrast to the urinary findings, arylsulfatase B activity in tumor tissue was elevated in only 27 of 110 of the specimens of colorectal cancer. In 55 patients treated with 5-fluorouracil, all of the 13 patients who showed objective response to therapy had activities of arylsulfatase B in the tumor tissue within the normal range for large bowel mucosa. Nevertheless, 22-26 of the 43 patients who did not respond also presented values in the normal range. It is concluded that increased cellular proliferation in colorectal cancer may be related to the changes in lysosomal arylsulfatase B activities. A pathogenic role for arylsulfatase and other lysosomal hydrolases is not peculiar to colorectal carcinoma, and has been noted in other diseases of the large bowel.

3485 ACUTE COLITIS IN THE RENAL ALLOGRAFT RECIPIENT. (Eng.) Perloff, L. J.; Chon, H.; Petrella, E. J.; Grossman, R. A.; Barker, C. F. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Ann. Surg.* 183(1):77-83; 1976.

Four renal allograft recipients with evidence of ischemic damage to the colon are presented and compared with 11 cases from five major series. Similarities in the patients included: deterioration of renal function, multiple immunosuppressive and antibiotic regimens, the use of cadaver renal allografts, and diagnostic and therapeutic measures requiring frequent barium and ion-exchange resin enemas. Two of the four allograft recipients underwent surgery for the removal of segments of necrotic colon after several weeks of fever and abdominal pain that was initially attributed to either acute rejection, viral infection, or pancreatitis. One patient had 3 days of melena and responded to nonoperative therapy. The fourth patient developed ischemic colonic changes 10 weeks after allograft nephrectomy and was receiving no immunosuppressive therapy at the time. Broad spectrum antibiotics were used at various times in all patients. Early aggressive evaluation of gastrointestinal complaints--including barium enema, upper gastrointestinal series with small bowel follow-through, proctosigmoidoscopy or colonoscopy, and arteriography--is indicated, in view of the lethality of the complication of colonic ulceration. The clinical pictures presented emphasize the fact that renal allograft recipients are commonly heir to many complications that are rare in the normal population.

3486 ISCHEMIA OF THE COLON. (Eng.) O'Connell, T. X.; Kadell, B.; Tompkins, R. K. (Univ. California School Medicine, Los Angeles, CA). *Surg. Gynecol. Obstet.* 142(3):337-342; 1976.

A discussion of ischemic colitis as it occurred in 26 patients is presented. In 10 patients, the splenic flexure was the only involved portion of the colon. This portion was involved together with the descending colon in another seven patients. The sigmoid colon was the site in three patients, the total colon in three, multiple skip areas in two, and the right side of the colon in one patient. Barium enema was the most helpful roentgenologic examination in the 16 patients in whom it was performed. Mucosal irregularity was noted in 11, narrowed lumen in 6, thumbprinting in 5, stricture in 2, and perforation in 1 patient. Twelve patients had a history of significant atherosclerotic vascular disease. Three patients with atherosclerosis had ischemia secondary to cholesterol emboli of the colonic vasculature, two had occlusion of the inferior mesenteric artery with poor collateral supply, and three subjects were taking antihypertensive medications that may have caused ischemia of the colon. Eight patients had malinant disease of the hematopoietic reticuloendothelial system, five had leukemia, and two had lymphoma. Colonic ischemia was a terminal condition in eight patients. Conservative treatment was given to seven patients; this involves maintenance on fluids given i.v., intestinal intubation to decrease intraluminal pressure and minimize metabolic needs of the colonic wall, antibiotics to counteract invasion of intraluminal bacteria into or through damaged colonic wall, and a low molecular weight dextran to expand the intravascular volume and prevent sludging of the blood in the small colonic vessels. Five patients underwent hemicolectomy. It is suggested that early intervention be recommended if prompt response to conservative treatment does not appear, provided that associated diseases do not contra-indicate operation.

3487 BENIGN EXTRINSIC LESIONS OF THE LARGE BOWEL SIMULATING A CARCINOMA OF THE COLON: REPORT OF 16 CASES. (Fre.) Govoni, A. F. (234 Warner Ave., Roslyn Heights, NY 11577). *J. Radiol. Electrol. Med. Nucl.* 56(1):61-70; 1975.

Sixteen cases of benign extrinsic lesions involving the colon and producing roentgen findings simulating a neoplasm are reported. Details and x-ray photos of the 16 cases, which included 5 inflamed epiploic appendages, 4 congenital fibrous bands, 3 adhesions, 2 cases of pancreatitis, and 1 case each of a paricecal abscess and an endometriosis, are presented. Pain was the presenting symptom in nine of the cases. Hemorrhage was present in two cases, and symptoms of occlusion were present in two cases. In the majority of cases, radiological signs were indistinguishable from those of an intrinsic lesion. Neoplasm was considered as a diagnosis in four of the cases. It is concluded that a correct diagnosis can be made if history, clinical, and physical signs are thoroughly analyzed. Similar cases reported in the literature are also reviewed.

3488 CEA LEVELS IN PATIENTS WITH COLORECTAL POLYPS. (Eng.) Doos, W. G.; Wolff, W. I.; Shinya, H.; DeChabon, A.; Stenger, R. J.; Gottlieb, L. S.; Zamcheck, N. (Boston City Hosp., Boston, MA). *Cancer* 36(6):1996-2003; 1975.

Pre-operative plasma carcinoembryonic antigen (CEA) levels were measured in 93 patients with histologically defined colorectal adenomata removed at fibroptic colonoscopy to determine whether CEA levels are elevated in patients with colonic polyps or whether they vary with different histologic patterns. None of the patients had inflammatory bowel disease, previous history of carcinoma, or evidence of liver disease. Fifteen percent of the patients had elevated CEA levels (≥2.5 ng/ml), and two-thirds of these were between 2.5 and 4.0 ng/ml. Increased association of elevated CEA levels was noted with old age, villous adenomas (two- to fourfold), and increased tumor size (>2.3-cm diameter; twofold), but not with foci of dysplasia or carcinoma *in situ.* The following observations were made in seven of the 14 patients with elevated CEA levels: 2 patients had villous tumors with carcinoma *in situ,* 1 patient had a villous adenoma, 2 patients had mixed villous and tubular adenomas (with a high proportion of villous pattern), and 2 were subsequently shown to have carcinoma elsewhere in the colon. It is uncertain that the polyps were the source of the elevated circulating CEA levels; other factors including smoking and patient selection need to be considered. This preliminary study suggests that patients with colorectal adenomata and elevated circulating CEA may be at higher risk for the development of carcinoma. Further follow-up studies of the malignant potential of the polyp-bearing colon are essential.

LARGE INTESTINE

Ulcerative Colitis

3511 THE PATHOLOGY OF THE APPENDIX IN ULCERATIVE COLITIS. (Eng.) Jahadi, M. R.; Shaw, M. L. (2202 Avenue L, Galveston, TX 77550). *Dis. Colon Rectum* 19(4):345-349; 1976.

The involvement of the appendix was evaluated in 65 patients with chronic ulcerative colitis, and the histopathologic changes that occur in the appendix during this disease are described. Twenty-two patients had appendectomies prior to resection of the bowel: 17 could not be evaluated, two had nonulcerative acute appendicitis, one had fibrous obliteration of the appendiceal lumen, and two had normal appendices. In the remaining 43 patients, no section was taken from the appendix in seven patients; six were reclassified as having Crohn's disease; six appendices were normal; fibrous obliteration occurred in six; and peri-appendicitis was found in four cases. The appendices of the remaining 14 patients manifested some form of inflammatory change, and were classified as being in the acute phase of disease, the resolving phase, the remission phase, or as nonspecific inflammation. All but one of seven patients with ulcerative colitis in the active phase in the appendix had a similar stage of activity in the resected colon; the patient with dissimilarity in the stages had remission in the colon. Of the three patients in whom the inflammatory reaction in the appendix was the resolving phase, one had a combination of resolving and remission phases in the colon, one had active disease in the colon, and the third had similar changes in the appendix and colon. The histologic findings in the two locations in the one patient with disease in remission were similar. Both patients with nonspecific inflammatory reactions had active stage colitis in the colon. A patient with evidence of all three stages in the appendix had a similar histopathologic change in the colon. The findings reveal that 78% of the patients with appendiceal involvement had similar changes in the colon and appendix, indicating a positive correlation between the stages of disease in these two locations.

3512 THE DETECTION OF SEROLOGICAL FACTORS IN ACUTE ULCERATIVE COLITIS INDICATING A FAVOURABLE SHORT-TERM PROGNOSIS. (Eng.) Hunt, P. S.; Trotter, S. (Prince Henry's Hosp., St. Kilda Road, Melbourne, Victoria 3004, Australia). *Aust. N.Z. J. Surg.* 46(1):88-91; 1976.

Experiments were conducted to determine serological factors that are indicative of a favorable short-term prognosis in acute ulcerative colitis. Colonic epithelial cells were obtained from operation specimens and by biopsy at sigmoidoscopy from 16 patients with severe acute mucosal ulcerative colitis and from 11 control subjects with normal large-bowel mucosa. The ability of lymphocytes to release ^{51}Cr label from large intestinal epithelial cells was quantitatively assessed as percentage lymphocyte activity. The mean ± standard deviation of percentage lymphocyte activity in 16 patients with acute ulcerative colitis on admission to hospital (88 ± 8%) was significantly greater than that in 11 normal subjects (16 ± 8%, $p<0.01$). Samples of autologous serum were added to two reactions between lymphocytes and autologous large intestinal epithelial cells. The results in the seven patients who had emergency colectomy differed significantly from those in the nine who responded to corticosteroid treatments. The mean serological inhibition of lymphocyte activity in the group who had colectomy was 44 ± 16%, and in those responding to steroids it was 12 ± 5%. When the serum of these patients was studied for immunofluorescent autoantibodies to normal human colonic mucosa, none of the seven patients treated by colectomy had detectable autoantibodies, in contrast with three of the nine patients with a more favorable short-term prognosis (i.e., those who responded to steroid treatment). It is suggested that some patients have a serological factor that blocks the *in vitro* action of cytotoxic lymphocytes.

3513 THE DISEASE ACTIVITY OF ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Talstad, I.; Gjone, E. (Haukeland Sykehus, 5000 Bergen, Norway). *Scand. J. Gastroenterol.* 11(4):403-408; 1976.

The disease activity in ulcerative colitis and Crohn's disease was studied in 114 patients with ulcerative colitis and in 44 patients with Crohn's disease affecting the large bowel (7), the small bowel (11), and both bowels (19). Parameters found to reflect the disease activity were given scores from 1 to 4. The score obtained by a patient was compared with the maximum scores, yielding a percentage of disease activity. In ulcerative colitis, highly significant regressions were found between the erythrocyte sedimentation rate (ESR), Hb, thrombocytes, serum albumin, immunoglobulin A, and the total binding capacity (TIBC, $p<0.001$ for all); less significant regressions were found for total serum protein, serum iron, and serum folic acid ($p<0.01$ for all). In Crohn's disease, the regression between the ESR and Hb ($p<0.001$), thrombocytes ($p<0.01$), and serum iron ($p<0.01$) resembled that found in ulcerative colitis. However, no significant regressions were found between the ESR and total serum protein, serum albumin, TIBC, and the Schilling test. Normal ESR was found in 10% of patients with severe Crohn's disease who had depressed total serum protein and albumin. The regressions between the percentage of disease activity and the ESR in ulcerative colitis and Crohn's disease were $p<0.001$ and $p<0.001$, resp. Mild, moderate, and severe ulcerative colitis or Crohn's disease roughly corresponded to the percentage disease activity of less than 30, 30-70, and greater than 70%, resp. It is proposed that these disease activities be used to define mild, moderate, and severe cases of ulcerative colitis and Crohn's disease.

3514 MUSCLE CELL ELECTROLYTES IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Valentin, N.; Nielsen, O. V.; Olesen, K. H. (Abovaenge 4, DK-2700 Copenhagen, Brh., Denmark). *Digestion* 13(5):284-290; 1975.

The intracellular electrolyte concentrations in skeletal muscle, from 15 patients with ulcerative colitis or Crohn's disease, were examined to determine the possible influence of potassium supplements and glucocorticoid treatment on the muscle electrolytes. Groups I, II, and III consisted of patients with ulcerative colitis (3), Crohn's disease (3), and ileostomy (3). Diarrhea was common in groups I and II. The patients in group IV (two with diarrhea and one with ileostomy) all received regular daily potassium supplements (50-100 mmol/day). Group V consisted of three patients with Crohn's disease and one with ulcerative colitis, but no diarrhea. Group VI was a control group. Glucocorticoid treatment was given to patients in all groups. Maintenance doses of prednisone were usually 20-30 mg/day. Many patients in groups I-III had low values of plasma sodium. Intracellular potassium and magnesium were low in patients of groups I and II. There were significant ($p<0.01$) reductions of plasma sodium and of intracellular potassium and magnesium concentrations in the patients with diarrhea (groups I, II, and III). The patients receiving potassium supplements (group IV) appeared to have a roughly normal electrolyte composition, except for low values of plasma potassium. No electrolyte abnormalities were found in group V or VI. The results strongly suggest that the compositional abnormalities seen in groups I and II are characteristic of chronic diarrhea rather than ulcerative colitis and Crohn's disease. The data from patients with ileostomy (group III) were not conclusive.

3515 CURRENT DIAGNOSIS OF NONSPECIFIC ULCERATIVE COLITIS IN CHILDREN. (Rus.) Kanshina, O. A.; Tukina, G. M.; Ginzburg, S. N.; Ivanova, L. M. (Moscow Scientific Res. Inst. Epidemiology and Microbiology, Moscow, USSR). *Vopr. Okhr. Materin. Det.* 20(12):23-27; 1975.

PANCREAS

3521 THE PANCREAS IN CYSTIC FIBROSIS: CHEMICAL COMPOSITION AND COMPARATIVE MORPHOLOGY. (Eng.) Kopito, L. E.; Shwachman, H.; Vawter, G. F.; Edlow, J. (Harvard Medical Sch., Boston, MA 02115). *Pediatr. Res.* 10(8):742-749; 1976.

Sections of pancreas from 16 individuals who died with cystic fibrosis (CF) were classified by morphometric criteria into categories in increasing order of pancreatic involvement. In addition, biochemical studies of the pancreas from 35 patients who died of CF were undertaken, and the results were compared to the severity of pancreatic involvement. The concentration of acini, islets, main ducts, lobular ducts, connective tissue, and fat was compared with levels obtained in pancreatic tissue from 17 normal controls. In the least involved pancreases, from neonates who died under 5 months of age, acini were reduced to 33% of control levels and the following were increased: islets to 410%, lobular ducts to 250%, and main ducts to 1700% of controls. With increasing severity of the pancreatic disease, the acini were further reduced to 5% and lobular ducts to 37% of control levels, resp. Main ducts increased by 19-fold, and fatty infiltration accounted for more than 25% of the fresh weight of the pancreas in 9 of the 16 specimens. Comparative biochemical studies of 35 fibrocystic pancreases showed that water and volatile matter, normally accounting for 80% of the weight of the fresh pancreas, was reduced to less than 30% in the most affected organs. The concentration of zinc diminished from near normal mean levels of 193 μg Zn/g dry pancreas to 10% of this amount in the severely involved pancreas. Elevated concentrations of calcium, amounting to over 10 times control level, were found in obstructed ductal structures. Calcium was depleted from pancreatic sections adjacent to the obstructions. The following biochemical indicators were significantly different in their mean levels in the 35 fibrocystic pancreases when compared with the 17 controls: ($p \leq 0.001$) fat, water, zinc, calcium, copper, magnesium, potassium, and sodium ($p \leq 0.01$). It is concluded that biochemical changes in the pancreas are quantitatively related to the severity of pancreatic involvement in CF.

3529 HEMORRHAGE IN THE PANCREATIC DUCT DURING THE EVOLUTION OF CHRONIC PANCREATITIS: OBSERVATION OF TWO NEW CASES. (Fre.) Gautier-Benoit, C.; Luez, J.; Vermesse, G.; Pinchon-Marsy, S.; Cecile, J. -P. (No affiliation given). *Lille Chir.* 30(4):74-76; 1975.

The difficulty of diagnosing hemorrhage in the pancreatic duct is illustrated in two cases of hemorrhage as a result of chronic pancreatitis. The first patient was hospitalized initially for pain in the hypochondrium. Acute pancreatitis was diagnosed on the basis of serum and urine amylase levels. The patient was treated medically and returned home. Two yr later, he was rehospitalized because of pain and bloody stools. Radiography of the gastrointestinal tract was negative as was arteriography of the celiac and mesenteric arteries. Anemia and bloody stools persisted, and further radiography revealed pancreatic calcification. A duodenoscopy detected blood at the level of the bile duct. A duodenopancreatectomy was performed. Histopathological examination of the excised pancreas confirmed the diagnosis of chronic pancreatitis and revealed a pseudocyst communicating with an artery and the pancreatic duct. The other patient developed chronic pancreatitis as a result of alcoholism. Anemia was attributed to the metabolic disorder. A duodenopancreatectomy was performed and fresh blood was observed in the pancreatic duct. Above the pancreatic duct, a necrotic area (about 1 cm^3 in size), which had ulcerated into the superior mesenteric vein, was discovered, accounting for the blood in the duct. Histopathological examination confirmed the diagnosis of chronic pancreatitis. Treatment of a ruptured blood vessel into the pancreatic duct can be accomplished by hemostasis followed by external or internal drainage of the pseudocyst or pancreatic ducts; however, excision of the involved area of the pancreas is preferable.

3530 INADEQUATE PARATHYROID RESPONSE IN ACUTE PANCREATITIS. (Eng.) Robertson, G. M., Jr.; Moore, E. W.; Switz, D. M.; Sizemore, G. W.; Estep, H. L. (Veterans Admin. Hosp., Richmond, VA 23298). *N. Engl. J. Med.* 294(10):512-516; 1976.

Nine consecutive hypocalcemic patients with acute pancreatitis were studied to elucidate the mechanism of hypocalcemia. Mean serum ionized calcium, 0.97 mM, was below the normal mean of 1.16 mM ($p<0.001$). Seven of eight patients tested had normal parathyroid hormone levels. All responded to parenteral parathyroid extract (200 U) by increasing serum ionized calcium and urinary cyclic AMP, indicating parathyroid hormone responsive target organs. Calcitonin and glucagon concentrations were increased above normal in some patients, but there was no relation with serum ionized calcium. Parenteral glucagon had no significant effect on serum ionized calcium or calcitonin concentrations. These findings suggest that neither glucagon nor calcitonin was primarily responsible for the hypocalcemia, which did not produce expected increases in serum parathyroid hormone concentrations. It is suggested that relative parathyroid insufficiency may account for the persistent hypocalcemia observed in patients with acute pancreatitis.

LIVER AND BILIARY TRACT

3540 THE CONSTITUTIONAL INDOCYANINE GREEN EXCRETORY DEFECT: REPORT OF FOUR CASES. (Eng.) Namihisa, T.; Nambu, M.; Kobayashi, N.; Kuroda, H. (Juntendo Univ. Sch. Medicine, Hongo 3-1-3, Bunkyo-ku, Tokyo, 113 Japan). *Gastroenterol. Jpn.* 10(1):70-76; 1975.

Case reports of four patients with high indocyanine green (ICG) secretory defects and without overt liver diseases are reported. The ICG retention rate at 15 min after a single i.v. injection of 0.5 mg/kg ranged from 69.4% to 78.4%, while the BSP retention rate at 45 min after an injection of 5 mg/kg ranged from 2.9% to 6.0%. The plasma disappearance rate of ICG ranged from 0.017 to 0.025, while the plasma disappearance rate of BSP ranged from 0.069 to 0.126. The transfer rate of ICG from plasma to liver decreased by two on the study of compartmental analysis, and a slightly reduced transfer rate of BSP from plasma to liver was also observed. The step formation was observed on both the ICG and BSP disappearance curves, 20-25 min after the injection, in all cases and in repeated observations. The serum containing

ICG or BSP was eluted through Sephadex G-200, and the eluted serum protein fraction showed three peaks (I, II, and III in order of elution). The ICG binding capacity of serum protein decreased in the first peak and increased in the third peak. Light microscopic findings showed the increase of lipofuscin-like lysome, modification and paracrystalline-like array of mitochondria, and increase of reticulum fiber in Disse's space. The father of one of the patients showed ICG retention without BSP retention. Five cases with this discrepancy of dyes in three generations of a kindred are known, and the characteristic impaired hepatic removal of ICG in these cases was suspected to be congenital or constitutional. The results suggest that the subjects reported in this study exhibit a new type of the dye excretory disorder associated with heredity.

3541 ENDOTHELIAL AND BILE CANALICULAR ALKALINE PHOSPHATASE IN HUMAN LIVER AND SERUM.

(Eng.) Hagerstrand, I.; Lindholm, K.; Lindroth, Y. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Clin. Lab. Invest.* 36(2):131-135; 1976.

Evidence to support identification of endothelial and bile canalicular alkaline phosphatase isoenzymes in serum samples is presented. In addition, the relation between hepatic and serum increases in bile canalicular isoenzymes was studied. The alkaline phosphatase in homogenates of human liver was separated into two components by the addition of Triton X-100 to an agarose gel electrophoretic system. One of these components migrated at a rate identical to that of the original one and at a rate similar to alpha$_2$-macroglobulin. The other component migrated more slowly, at a rate that resembled that of beta$_1$-transferrin. Human serum samples regularly contained an identical fast-migrating fraction, whereas an identical slowly migrating fraction only appeared in serum obtained from patients with various diseases, especially from patients with malignant tumors, even though the liver did not contain tumor metastases. Slow isoenzyme was found in a few sera that had alkaline phosphatase activity within the normal range. Histochemical examinations of liver tissue from patients whose serum contained the slowly migrating isoenzyme showed a pronounced reaction of alkaline phosphatase in the bile canaliculi, and this isoenzyme seemed to arise from the canaliculi. It is suggested that the fast-migrating isoenzyme arises from the endothelial cells of the liver to which the activity is usually confined in histochemical stainings. It is also suggested that malignant tumors, collagen diseases, and chronic biliary obstruction increase bile canalicular isoenzyme in serum.

3542 MORPHOLOGICAL ASPECTS OF THE LYMPH VESSEL SYSTEM OF THE LIVER.

(Ger.) Huth, F. (Pathologisches Institut der Universitat, D-4000 Dusseldorf, Moorenstrasse 5, W. Germany). *Leber Magen Darm* 4(6):262-273; 1974.

Morphologic aspects of the lymph vessel system of the liver are described. The system originates in capillaries ending blindly in interlobular septa. The lymphatic capillaries do not have basal membranes. Physiologic and electron microscope studies have shown that intercellular spaces of the endothelium of the lymphatic vessels allow rapid resorption of high molecular proteins, corpuscular substances, and cells by the surrounding tissue. Lymphostasis in the liver can be brought about experimentally by ligating efferent lymph vessels, by blocking the ductus thoracicus, by encapsulating the liver, or by displacing the liver. Hepatic lymphostasis in man is to be expected in cases where there are inflammatory-fibrotic processes, tumors, or certain pathologic processes caused by parasites in the hilar area; it can also be seen in cases of aplasia or hypoplasia of the lymphatic vessels of the liver. In experimental cholestasis, as well as in biliary obstructive diseases in man, bile flow into the lymphatic system occurs as a compensatory mechanism. Consequently, lymphostasis aggravates the effects of cholestasis experimentally. Intrahepatic lymphangitis has been described in a few patients with hepatitis. Ascension of infections to the liver by way of the lymphatic system from a pericholecystitic or another inflammatory focus has never been proven. The increase in number and diameter of lymphatic vessels in cirrhosis of the liver has been proven by endoscopic, radiographic, and anatomical investigations. However, the role of the hepatic lymph vessel system in many other liver diseases has yet to be clarified.

3543 ULTRASTRUCTURAL ALTERATIONS IN LIVERS WITH METASTASIS.

(Eng.) Albukerk, J.; Duffy, J. L. (Health Sciences Center, State Univ. New York at Stony Brook, Stony Brook, NY). *Arch. Pathol. Lab. Med.* 100(3):168-171; 1976.

Thirteen biopsy specimens of livers that contained metastatic carcinoma were examined with the electron microscope. Degenerative alterations of the mitochondria, cystic dilatation of the endoplasmic reticulum, increased amounts of osmiophilic material, some in various stages of autophagocytosis, and lipid vacuoles within the hepatocytes were observed. In 10 of 13 cases, the hepatocytes demonstrated mitochondrial paracrystalline inclusions of various sizes (0.8μ-3μ). The observation of the latter structures in edematous hepatocytes containing phospholipid-rich osmiophilic deposits supports the hypothesis that paracrystalline inclusions are caused by the precipitation of unmasked phospholipids. The spectrum of ultrastructural findings suggests hypoxia and impaired lipid metabolism of the hepatic tissue as a result of congestion and bile stasis caused by the tumor nodules.

3544 STUDIES OF LIVER FUNCTION AND STRUCTURE IN PATIENTS WITH GALLSTONES BEFORE AND DURING TREATMENT WITH CHENODEOXYCHOLIC ACID.

(Eng.) Fromm, H.; Holz-Slomczyk, M.; Zobl, H.; Schmidt, E.; Schmidt, F. W. (Medizinische Hochschule, D-3 Hannover 61, Postfach 610 180, W. Germany). *Acta Hepatogastroenterol (Stuttg.)* 22(6):359-369; 1975.

Liver function and structure were studied before and during the treatment of 12 patients with radiolucent gallstones. Patients received chenodeoxycholic acid (CDCA, 20 mg/kg/day) for 3-22 months. No signs of hepatotoxicity were observed. Activities of several enzymes, including transaminases, glutamate dehydrogenase, and γ-glutamyl transferase were frequently abnormal in this group of patients; however, there was no statistically significant difference between treatment and pretreatment levels. Serum bilirubin and protein electrophoresis remained normal throughout the study. The BSP retention test was not significantly altered by CDCA treatment. Light microscopic examination in eight patients revealed no changes of liver structure during 3-19 months of CDCA administration, except for a decrease in fatty changes in three patients; in these patients, changes affected 25-50% of hepatocytes before treatment. The ultrastructure of liver cells was normal in five patients in whom electron microscopy was also done. The evidence suggests that CDCA is a safe and effective drug for the treatment of radiolucent gallstones.

3545 DIAGNOSIS OF CYSTIC LESIONS OF THE LIVER WITH SPECIAL REFERENCE TO THE VALUE OF DIAGNOSTIC ULTRASOUND. (Eng.) Thijs, L. G.; Snel, P. (Free Univ. Hosp., Amsterdam, Netherlands). *Neth. J. Med.* 18(6):234-244; 1975.

All cases of cystic liver disease encountered in a hospital during the last 9 yr were reviewed with emphasis on diagnostic procedures. Eighteen patients with liver cysts were traced from the available records, but the presence of liver cysts was not suspected clinically in 12 cases. A liver scan was performed in only five patients of the whole series. In three patients, the cysts were less than 3 cm in diameter, which is generally considered clinically undetectable. In all other patients, the cysts were large enough to have been discovered if looked for with presently available diagnostic methods. Ultrasound is a valuable diagnostic tool, and case histories of four patients in whom ultrasonic investigations of the liver were carried out are presented. Several factors should be considered in the decision of which sequence of tests to follow for a particular patient including: inconvenience and hazards for the patient and specific skill and experience of the investigator. Based upon present experience, it is concluded that a radioisotope should be the first diagnostic step in a case of suspected cystic lesion of the liver, and ultrasonic examination should be the second.

3546 THE CURRENT STATUS OF α-1-ANTITRYPSIN, A PROTEASE INHIBITOR, IN GASTROINTESTINAL DISEASE. (Eng.) Sharp, H. L. (Univ. Minnesota Hosps., Minneapolis, MN 55455). *Gastroenterology* 70(4):611-621; 1976.

The relation between extremely deficient levels of α-1-antitrypsin (α1AT), a glycoprotein synthesized in the liver, and predisposition to the development of cirrhosis and emphysema is reviewed. Cirrhosis, characterized by a distinctive hepatocyte abnormality (eosinophilic cytoplasmic globules), usually has its onset in childhood. Depressed levels of α1AT are also observed in celiac disease and peptic ulcers, and minimal glomerular lesions are frequently observed in the postmortem examination of cirrhotics. Emphysema associated with α1AT deficiency is characterized by onset in early adulthood, equal sex distribution, and predisposition for the lower lobes. Respiratory distress syndrome in the newborn has been associated with low levels of α1AT on a nongenetic basis. Pathogenic hypotheses are discussed for both liver and lung lesions. Treatment is largely supportive. Steroids have been tried, but have generally been without demonstrable effect. Liver transplant resulted in a return of serum α1AT to normal levels, but the two patients in whom this was tried died of complications of the procedure. It is concluded that although biochemical advances in defining the nature of α1AT deficiency are progressing, the pathogenesis of the disease remains an enigma.

3547 OBSERVATIONS OF INCREASED LEVELS OF BLOOD COAGULATION FACTORS AND OTHER PLASMA PROTEINS IN CHOLESTATIC LIVER DISEASE. (Eng.) Cederblad, G.; Korsan-Bengtsen, K.; Olsson, R. (Sahlgren's Hosp., S-413 45, Goteborg, Sweden). *Scand. J. Gastroenterol.* 11(4):391-396; 1976.

The levels of blood coagulation factors and other plasma proteins in eight primary biliary cirrhosis (PBC) patients were compared with the levels in seven patients with common duct stone (CDS) and six patients with chronic active hepatitis (CAH). The PBC and DCS patients generally had coagulation factor levels above 100%. In contrast, the CAH patients generally had median values of the different hemostatic factors below 100%. Statistically significant differences were observed between CAH and PBC patients for all hemostatic factors except VIII, IX, and XI and between CAH and CDS patients for all hemostatic factors except II, VII, VIII, X, and XII. All the PBC patients had immunoglobulin (Ig) M and ceruloplasmin values above the normal range in the laboratory. In contrast, the CAH patients had beta$_{1c}$/$_{1a}$-globulin and orosomucoid values below the lower reference limit. All the CDS patients showed ceruloplasmin values above the upper reference limit. In comparison with the PBC and CDS patients, the CAH patients had significantly lower levels of orosomucoid, ceruloplasmin, beta$_{1c}$-$_{1a}$-globulin, beta$_{1e}$-globulin, and a higher level of IgG. The CDS patients differed from PBC patients in having significantly lower IgM and ceruloplasmin levels and higher transferrin levels. The results indicate that there is an increase of wide range of liver synthesized proteins in cholestatic liver disease.

3548 IS CHOLESTASIS DUE TO MICROFILAMENT FAILURE? (Eng.) French, S. W. (Univ. California Sch. Medicine, Davis, CA). *Hum. Pathol.* 7(3):243-244; 1976.

The hypothesis that cholestasis is due to the failure of microfilaments to contract is reviewed. Evidence indicates that microfilaments are located in the pericanalicular region and that the pericanalicular microfilaments contain contractile proteins. It has also been shown that agents known to affect microfilament function, such as cytochalasin B, also cause cholestasis. Evidence that bile flow is mediated through cyclic contraction and relaxation of the microfilaments is indirect and circumstantial. Some characteristics of bile flow and bile pressure suggest that a smooth muscle-like action is involved. Cholestasis could result from any agent that interferes with the hormone receptor-stimulated contraction of the pericanalicular microfilaments. It is suggested that direct evidence linking hormonal receptor-mediated microfilament contraction to bile flow is necessary to establish whether microfilaments play a role in bile flow and cholestasis.

3549 BILE ACIDS IN RECURRENT BENIGN CHOLESTASIS. (Fre.) Levy, V. G.; Bereziat, G. (C.H.U. Saint-Antoine, 184, Rue du Faubourg-St.-Antoine, F 75571 Paris Cedex 12, France). *Nouv. Presse Med.* 4(36):2599-2600; 1975.

Bile acid (BA) rates were determined (Sandberg modified Roovers technique) in three patients with benign recurrent cholestasis. In the first two patients (mother and daughter), a vesicular lithiasis accompanied the cholestasis; the mother also had jaundice during all of her five pregnancies. The third patient had very high BA rates at each recurrence. High BA rates in his father support the familial character of this illness. High BA rates were also found during remission in all three patients; this may be indicative of the latent illness, causing a disorder in bile excretion, or it may be indicative of a primary excess of BA synthesis, requiring cholestyramine treatment. The presence of biliary lithiasis supports the first hypothesis.

3550 PROGRESSION IN HEMOCHROMATOSIS. (Fre.) Bercovici, J. P.; Leuzinger, D. (C.H.U., 29279 Brest Cedex, France). *Nouv. Presse Med.* 4(31):2257-2258; 1975.

The case of a 42-year-old diabetic patient with hemochromatosis who developed a cancer of the liver accompanied by polycythemia, alpha-fetoprotein secretion, and hypoglycemia is presented. The tumor grew rapidly, and nodal, pleuropulmonary, endocardial, and adrenal metastases appeared. Blood volume increased due to liver cirrhosis. Polycythemia necessitated the removal of 5.6 l of blood in 2 months. There was also a sizable drop in blood iron levels in the liver, most probably related to the blood removal and the iron consumption of an exacerbated erythropoiesis. High rates of the latter were noted in the plasma and in the hepatic tumor. The patient died from cardiac arrythmia with complete auriculoventricular dissociation. It appears that the liver is active in the biological inactivation of erythropoietin. The high degree of plasmatic erythropoietic activity in certain patients with hepatoma and polycythemia suggests the disappearance of a feedback mechanism followed by inappropriate synthesis of a protein that is identical or similar to erythropoietin. Alpha-fetoprotein is usually associated with a primary liver cancer.

3551 REYE SYNDROME: TREATMENT BY EXCHANGE TRANSFUSION WITH SPECIAL REFERENCE TO THE 1974 EPIDEMIC IN CINCINNATI, OHIO. (Eng.) Bobo, R. C.; Schubert, W. K.; Partin, J. C.; Partin, J. S. (Univ. Cincinnati Coll. Medicine, Cincinnati, OH). *J. Pediatr.* 87(6):881-886; 1975.

The treatment of 66 patients with Reye's syndrome established by hepatic biopsy or autopsy is described. Particular attention is given to 26 patients treated during the 1974 epidemic in Cincinnati. Prior to the utilization of exchange transfusion early in the course of disease, the case fatality rate was 100% in nine patients. With early diagnosis and early exchange transfusion, the case fatality rate was reduced to 27% in 44 patients. During the 1974 epidemic of Reye's syndrome, 18 of 26 children who were treated were diagnosed by hepatic biopsy; 16 received one or more exchange transfusions. There were no deaths among these 26 patients. During the 1974 epidemic, the national case fatality rate was estimated at 40%. It is proposed that both early diagnosis and prompt exchange transfusion improve survival in children with Reye's syndrome and that prompt action by the practicing pediatrician can reduce the case fatality rate by 50% or more.

3552 THORIUM INDUCED HEPATIC HEMANGIOENDOTHELIOMA. ROENTGEN-ANGIOGRAPHIC FINDINGS IN TWO ADDITIONAL CASES WITH CLINICAL "INFORM AND CONSENT" PROBLEMS. (Eng.) Curry, J. L.; Johnson, W. G.; Feinberg, D. H.; Updegrove, J. H. (Easton Hosp., Easton, PA 18042). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(3):671-677; 1975.

Two cases of presumed thorium induced hemangioendothelioma of the liver are reported. A 52-yr-old woman presented with a subjective feeling of generalized puffiness. A chest roentgenogram showed thorium deposits in the liver, spleen, and lymph nodes. There were marked increases in alkaline phosphatase and SGOT levels. The patient underwent thorotrast cerebral angiography 26 yr previously. One yr after presentation, the patient showed weight loss and a slightly enlarged liver. Two yr following, there was severe pain, a markedly enlarged liver, and hepatomegaly. Celiac angiography revealed hepatic replacement by large vascular lakes, which remained opacified for more than 30 sec. The patient continued to lose ground and died 4.5 yr after initial presentation. The autopsy revealed microscopic hemangioendothelioma in the bone marrow, adrenal gland, and kidney. In the bone marrow specimens, angiosarcomas were accompanied by regional thorium deposits, which were not present within the malignant cells. A 54-yr-old acutely ill man also showed roentgenological evidence of thorium deposits and large diffused vascular lakes, which opacified for 45 sec. This patient also had a thorotrast cerebral angiogram 28 yr previously. The patient underwent an emergency laparotomy because of severe bleeding, but expired 8 days postoperatively. These are the first reports of angiography of the thorotrast liver, before and after clinical evolution of malignancy. It is suggested that angiography may have therapeutic and prognostic value in such cases.

3553 OBSERVATIONS ON THE ORAL ADMINSTRATION AND TOXICITY OF VINYL CHLORIDE IN RATS. (Eng.) Feron, V. J.; Speek, A. J.; Willems, M. I.; van Battum, D.; de Groot, A. P. (Central Inst. Nutrition Food Res. [CIVO] TNO, Utrechtseweg 48, Zeist, Netherlands). *Food Cosmet. Toxicol.* 13(6): 633-638; 1975.

The p.o. administration of vinyl chloride monomer (VCM) and its toxicity were studied in male and female Wistar rats. Upon storage, solutions of VCM in soybean oil appeared to be stable with respect to their VCM content and the fatty acid composition of the oil. In addition, no oligomers of vinyl chloride or reaction products of VCM with components of the oil were detected. Gastric incubation of such solutions was considered an acceptable method of p.o. administration of VCM to rats in short-term toxicity studies. Within 4 hr following intragastric intubation of VCM in soybean oil (300 mg VCM/kg), over 92% of the VCM administered was recovered from the gases excreted by the animals. Eructation did not appear to be involved in the excretion of VCM. VCM dissolved in soybean oil was administered by gavage to male and female rats at 0, 30, 100, and 300 mg/kg, once daily for 6 days per week for 13 weeks. Several hematological, biochemical, and organ weight values differed significantly from those of the controls, but these differences were considered to have only minor, if any, toxicological significance. A slight increase in liver-to-body weight ratio occurred in males and females at the highest level. This increase was not accompanied by liver damage, as was evident from histological examination, enzyme histochemistry, and electron microscopy. The no-effect level in this 90-day study was conservatively placed at 30 mg VCM/kg body weight, but it was probably higher, since the effects occurring at 100 and 300 mg/kg body weight were of doubtful toxicological significance. The results indicate that feeding rats with diets containing polyvinyl chloride (PVC) powder with a high VCM content is a more practical method for the long-term p.o. exposure of rats to VCM than is stomach intubation of VCM in oil. VCM was almost completely released from PVC powder during passage through the digestive tract.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

3591 BILIRUBIN AND PARANITROPHENOL GLUCURONYL TRANSFERASE ACTIVITIES OF THE LIVER IN PATIENTS WITH GILBERT'S SYNDROME: AN ATTEMPT AT A BIOCHEMICAL BREAKDOWN OF THE GILBERT'S SYNDROME. (Eng.) Auclair, C.; Hakim, J.; Boivin, P.; Troube, H.; Boucherot, J. (Unite de Recherches 24 de l'INSERM, Hopital Beaujon, F92110 Clichy, France). *Enzyme* 21(2):97-107; 1976.

Hepatic bilirubin (Bil-GT) and paranitrophenol glucuronyl transferase (PNP-GT) activities were measured in 26 patients with Gilbert's syndrome (GS) and in 1 patient with Crigler-Najjar type syndrome. Three groups of patients in GS were distinguished. In the first group, Bil-GT activity was decreased by 25% of that of the controls, and PNP-GT activity was normal. In the second group, Bil-GT was decreased by 25% of that of the controls, and PNP-GT was decreased by 50% of that of the controls. In the third group, Bil-GT was decreased by 50% of that of the controls, and PNP-GT activity was normal. In the Crigler-Najjar syndrome type 2, Bil-GT activity was 25% of that of the controls, and PNP-GT was 10% of that of the controls. The authors hypothesize that (a) the subjects of the third GS group were probably heterozygous to the homozygous disease that affected the subjects of the first GS group, and (b) the subjects of the second GS group were most likely heterozygous to the homozygous disease that affected the patient with Crigler-Najjar type 2. It is concluded that the proposed GS classification scheme requires confirmation.

Nonviral Hepatitis and Hepatic Injury

3593 UNDIFFERENTIATED PATTERNS OF KEY CARBOHYDRATE-METABOLIZING ENZYMES IN INJURED LIVERS: I. ACUTE CARBON-TETRACHLORIDE INTOXICATION OF RAT. (Eng.) Taketa, K.; Tanaka, A.; Watanabe, A.; Takesue, A.; Aoe, H.; Kosaka, K. (Okayama Univ. Medical Sch., 5-1 2-Chome, Shikata-cho, Okayama 700, Japan). *Enzyme* 21(2):158-173; 1976.

An undifferentiated pattern of key glycolytic, gluconeogenic, and pentose phosphate pathway enzymes was studied in carbon tetrachloride-injured male Sprague-Dawley rat liver, and it was compared with enzyme patterns in livers of various differentiated states. Acute carbon tetrachloride injury caused marked increases in activities of low hexokinase (18.9), glucose-6-phosphate dehydrogenase (101), phosphofructokinase (53), aldolase A (104), and pyruvate kinase M_2 (1.073 mU/mg protein) with concomitant decreases in activities of high hexokinase (1.8), glucose-6-phosphatase (35.4), fructose-1,6-diphosphatase (125), aldolase B, and pyruvate kinase L (89 mU/mg protein) as compared with the activities in control starved rats. These changes following carbon tetrachloride intoxication were different from enzyme changes induced by dietary alteration such as starvation and refeeding on a high carbohydrate fat-free diet, and were similar to those found in less differentiated liver tissues such as fetal liver and hepatoma AH 130. The deviation of hepatectomized animals from the adult liver group was minimal, indicating that the regenerating liver after partial hepatectomy was fairly well differentiated in enzyme composition. It is also suggested that refed and starved livers can be readily distinguished by their enzyme patterns.

3594 METHYLDOPA-INDUCED LIVER INJURY: RAPID PROGRESSION TO FATAL POSTNECROTIC CIRRHOSIS. (Eng.) Thomas, E.; Bhuta, S.; Rosenthal, W. S. (New York Medical Coll., Fifth Ave. at 106th St., New York, NY 10029). *Arch. Pathol. Lab. Med.* 100(3):132-135; 1976.

The case of a 55-yr-old woman who developed symptoms suggestive of hepatitis 12 weeks after first receiving methyldopa for hypertension is presented. Liver biopsy showed chronic aggressive hepatitis with subacute hepatic necrosis. Methyldopa was discontinued, but after exhibiting transient clinical improvement, the patient's condition progressively deteriorated until she died of hepatic failure, in spite of therapy with massive doses of corticosteroids and other nonspecific measures. During the terminal stage, a considerable decrease in the size of the liver was observed. At autopsy, the liver was found to be small, shrunken, and scarred; histological sections demonstrated postnecrotic cirrhosis. Such a rapid progression of methyldopa-induced liver injury is undoubtedly rare, but it may be prevented by careful supervision of patients who exhibit liver function abnormalities early in the course of therapy.

3595 ISONIAZID LIVER INJURY: CLINICAL SPECTRUM, PATHOLOGY, AND PROBABLE PATHOGENESIS. (Eng.) Mitchell, J. R.; Zimmerman, H. J.; Ishak, K. G.; Thorgeirsson, U. P.; Timbrell, J. A.; Snodgrass, W. R.; Nelson, S. D. (Natl. Heart and Lung Inst., Bldg. 10, Room 8N-115, Natl. Insts. Health, Bethesda, MD 20014). *Ann. Intern. Med.* 84(2):181-192; 1976.

A blind prospective evaluation of the prevalence and course of isoniazid associated liver injury was conducted in 358 hospitalized male psychiatric patients. All patients were housed in buildings where an outbreak of tuberculosis had occurred. Almost two-thirds of the patients were tuberculin reactors and received isoniazid. Patients who received 0.007-15.5 μg/ml isoniazid had a higher frequency of SGOT elevations than controls. Of 173 patients who completed at least 24 weeks of isoniazid therapy, 66 had at least one SGOT value of 30+ mU/ml, and 23 had at least one value of 60+. The frequency of SGOT abnormalities increased with the age of patients. Eight of the 23 had abnormal total bilirubin concentrations (greater than 1.2 mg/dl). In seven of these, elevation of total bilirubin concentration coincided both chronologically and proportionally with the degree of SGOT abnormality, showing that the elevated SGOT values were indicative of liver injury. Only 10 of 123 patients in whom the rate of isoniazid metabolism was determined during the 48th week of study had a positive fluorescent antinuclear antibody test. No antibodies to isoniazid were detected in any of the sera. It is concluded that the actual frequency of isoniazid related hepatic damage is difficult to determine, because many of the patients received other potentially hepatotoxic drugs concomitantly, particularly phenothiazine tranquilizers. Administration of isoniazid to this population caused hepatic injury in at least 10.5% and possibly in 22.9% of the patients.

3596 GRANULOMATOUS HEPATITIS ASSOCIATED WITH ACQUIRED TOXOPLASMOSIS IN ADULTS. (Fre.) Martinez-Vazquez, J. M.; Guardia, J.; Pahissa, A.; Moragas, A.; Mirada, A.; Tornos, J.; Bacardi, R. (Dept. Internal Medicine, Free Univ., Barcelona, Spain). *Sem. Hop. Paris* 51(14):963-965; 1975.

The case of a 34-yr-old man with granulomatous hepatitis associated with acquired toxoplasmosis is presented. The patient presented with prolonged fever hepatomegaly, and splenomegaly. Hepatic biopsy revealed small granulomas, which were bordered by epithelioid cells and round cells with fibrinoid necrosis. Positive tests included: antitoxoplasm antibodies (immunofluorescence, IgM 1/300, IgG 1/1,200), and complement fixation with the toxoplasmic antigen (1/64); sero-agglutination was specific (1/256). The patient was treated with pyrimethamine and sulfadiazone leading to a rapid regression of the fever and disappearance of the granulomas. The diagnosis of toxoplasmosis is supported by the serological data, especially the presence of IgM antibody, specific agglutination, and complement fixation with the toxoplasmic antigen; all were present during the acute phase of the illness and subsequently diminished. The relation between the granulomas and the toxoplasmosis seems likely, since the granulomas disappeared following therapy, and the patient fully recovered.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

3601 EPIDEMIOLOGY AND MODE OF TRANSMISSION OF VIRAL HEPATITIS A AND B. (Eng.) Deinhardt, F. (Rush-Presbyterian-St. Luke's Medical Center, 1753 West Congress Parkway, Chicago, IL 60612). *Am. J. Clin. Pathol.* 65(5):890-897; 1976.

The epidemiology and mode of transmission of viral hepatitis A (HA, epidemic or short incubation period hepatitis), hepatitis B (HB, homologous serum or post-transfusion hepatitis), and hepatitis C are reviewed. The incidence of hepatitis on a worldwide basis increased from 1959-1971 with a steady decline thereafter. About 40,000-50,000 cases of HA and 6,000-9,000 cases of HB are reported annually in the United States. It ranks fourth on a list of notifiable infectious diseases. Hepatitis A is usually transmitted by the anal-oral route and occurs endemically and epidemically (principally fecal contamination of food, drinking water, and swimming pools or lakes). Hepatitis B is transmitted by direct inoculation, but probably almost as frequently by nonparenteral routes (saliva or droplet infection from upper respiratory secretions) and is usually endemic. Hepatitis C, which is non-A-non-B hepatitis, occurs after transfusion and may account for more cases of post-transfusion hepatitis than HA and HB together. Both HA and HB can be diagnosed accurately by their respective antigens and corresponding antibodies. In contrast, little is known about the characteristics of HC.

3602 VIRAL HEPATITIS IN PAEDIATRIC AGE. (Eng.) Tolentino, P. (Dept. Infectious Diseases, Univ. Genoa, Genoa, Italy). *Paediatrician* 4(2/3): 93-102; 1975.

Recent advances in the epidemiology of hepatitis A and B viruses and the discovery of Australia antigen are reviewed. Viral hepatitis has a high lethality, as much as 30%, during early infancy and the first semester of life, and it presents some puzzling diagnostic problems in neonates. Hepatitis in older children represents a minor problem as most cases are mild, anicteric or subicteric, with a mild course and short duration. In the school age child, there is a higher incidence of icteric and prolonged diseases. Approaching the pubertal age, the disease more closely resembles the adult forms. Cholestatic forms, characterized by prolonged high values of bilirubinemia and itching, are infrequent in childhood. Fulminant forms are a major problem due to a massive hepatic necrosis and are clinically characterized by a new peak of fever, increasing icterus, neurological and psychical signs, and hemorrhages. Mild cases of hepatitis in childhood require no special treatment, except rest and a diet rich in proteins and carbohydrates and poor in lipids and salts. Ascorbic acid, B-complex, and non-17-alkylated protein anabolic steroids may be useful. Cortisone is not indicated in HBAg-positive cases as it may cause relapses and allow evolution to the chronic form. Cortisone may be indicated in the cholestatic forms. In fulminant hepatitis, several therapies are proposed including glucocorticoids in high dosage, hyperimmune serum or gammaglobulins, levodopa, heparin in high dosage, exsanguine transfusion or plasmapheresis, hemodialysis and peritoneal dialysis, cross-circulation with baboons, or extracorporeal circulation in pig's liver. These different techniques can be employed to permit liver regeneration in the case of partial necrosis. Temporary improvement of the clinical, biochemical, and sometimes histological findings were obtained in children with chronic hepatitis by using the anti-inflammatory and immunoderepressive treatment with glucocorticoids and azathioprine formerly employed in adults.

3603 GENETIC FACTORS AND AUTOIMMUNITY IN VIRAL HEPATITIS. (Eng.) Hug, G. (Univ. Cincinnati Med. Coll., Cincinnati, OH 45229). *Am. J. Clin. Pathol.* 65(5):870-875; 1976.

Studies on genetic factors and autoimmunity in viral hepatitis are reviewed, and the finding of hepatitis B surface antigen (HBsAg) in 166 children with a variety of diseases is reported. The development of the HBsAg carrier state may depend upon a patient's genome. The HBsAg subtypes may reflect the viral genome and may be of prognostic significance. The hepatitis B virus surface antigen of a given individual can be expressed as HBsAg/adw. Different subtypes predominate in different populations throughout the world. Altered immune response, as in patients with Down's syndrome, may increase the HBsAg carrier rate (30% in Down's syndrome as compared with 10% in other conditions of mental retardation). The difference between the carrier rates of the two patient groups indicates that patients who have Down's syndrome are particularly susceptible to becoming HBsAg carriers. Auto-antibodies have been used to differentiate various types of hepatitis. There is an increased incidence of histocompatibility antigen HL-A1 and HL-A8 in patients who have chronic aggressive hepatitis. In primary hepatic carcinoma, the HBsAg carrier rate is increased. Because neonatal hepatitis, biliary atresia, and choledochal cyst may all result from infantile obstructive cholangiopathy, with the precise outcome depending upon the presence of other conditions such as α_1-antitrypsin deficiency, a study of HBsAg was made in 166 children. They had a variety of diseases including Reye's syndrome, α_1-antitrypsin deficiency, and renal disorders. The HBsAg rate in the sera of these patients was normal.

3604 FAMILIAL CLUSTERING OF HEPATITIS B ANTIGEN AND LIVER DISEASES IN FAMILIES WITH A HIGH INCIDENCE OF VIRAL HEPATITIS. (Eng.) Piccinino, F.; Manzillo, G.; Sagnelli, E.; Balestrieri, G.; Maio, G. (First Medical Sch., Univ. Naples, Via D. Cotugno 1, 80135 Naples, Italy). *Infection* 3(2):99-104; 1975.

Twenty-three families, in which two or more cases of acute hepatitis-like jaundice (index cases) occurred, all were studied to evaluate hepatitis B antigen (HBAg) clustering and the incidence of asymptomatic liver disease. There were 49 "index cases" of hepatitis-like jaundice: 38 cases of acute viral hepatitis, 5 of chronic aggressive hepatitis, and 6 of active cirrhosis. The overall number of members in these families (excluding index cases) was 170, and 155 of these were tested by clinical examination, laboratory tests, and needle liver biopsy. In 27 of the 155 subjects, there was evidence of liver diseases (10 non-icteric hepatitis cases, 12 CAH cases, and 5 cirrhosis cases). HBAg was present in the serum of 19 of these patients, and 2 of the cirrhotic patients were positive. Furthermore, 33 of the 155 cases were healthy HBAg carriers who showed no abnormality in liver function tests. In the majority of these carriers, liver histology showed slight damage (pin-head necrosis or portitis), sometimes compatible with resolving viral hepatitis. A long-term follow-up of the HBAg carriers showed that three of these subjects progressed to acute viral hepatitis. Of 163 children, 35% had HBAg-positive liver disease and 19% were healthy HBAg carriers; this compared with incidences of 9.8% HBAg-positive liver disease and 4.9% HBAg carriers in 41 parents. The high frequency of both acute and chronic asymptomatic liver disease demonstrates the value of complete clinical investigation of the contacts when a case of viral hepatitis occurs in a family. It is suggested that genetic factors may be responsible for the development of a previously acute viral hepatitis to a chronic state.

3605 HEPATITIS B ANTIGEN IN INFANTS BORN TO MOTHERS WITH CHRONIC HEPATITIS B ANTIGENEMIA IN TAIWAN. (Eng.) Anderson, K. E.; Stevens, C. E.; Tsuei, J. J.; Lee, W.-C.; Sun, S.-C.; Beasley, R. P. (Rockefeller Univ. Hosp., New York, NY). *Am. J. Dis. Child.* 129(12):1389-1392; 1975.

Studies were undertaken to determine whether infants born to hepatitis B antigen (HBAg) carriers develop hepatitis B antigenemia. HBAg was detected by complement fixation (CF) in serum samples of 7.5% of 1,106 pregnant Chinese women tested in Taipei, Taiwan. HBAg persisted in all but one of 42 women followed for 1-18 months (average, 9 months) after delivery, and 27 of the 43 infants born to those women became antigen-positive. Persistence of the antigen was more common than transient or intermittent antigenemia. Twelve had antigenemia when first tested, while 15 later developed antigenemia, usually during the first 6 months of life. Only one infant developed antibody to HBAg (anti-HBAg), and this occurred after transient antigenemia. The HBAg was found in 2 of 32 fathers, and in 18 of 27 older siblings. The antigen was more common among siblings of antigen-positive than among those of antigen-negative infants. These findings demonstrate that in Taiwan, infants born to mothers who are asymptomatic carriers of HBAg commonly become infected by hepatitis B virus. Exposure of infants near the time of birth may be important in maintaining the high, chronic HBAg carrier rate in Taiwan.

3606 CELLULAR PATHOPHYSIOLOGY OF HEPATITIS. (Eng.) Trump, B. F.; Kim, K. M.; Iseri, O. A. (Univ. Maryland Sch. Medicine, 31

South Green St., Baltimore, MD 21201). *Am. J. Clin. Pathol.* 65(5):828-847; 1976.

The cellular pathophysiology of hepatitis is described, and a new hypothesis concerning the sequence of events in hepatic parenchymal cells is presented. The initial event involves virus-hepatocyte interaction, possibly involving antibody and complement. This results in damage to the plasma membrane, increasing the passive permeability to ions and involving inactivation of the transport pumps or ATPases within the structure. More serious events involve the exchanges of calcium between the cell and the extracellular fluid and between various compartments within the cell. Calcium is sequestered normally in segregation sites within the mitochondria. If this process is interfered with, these granules disperse and the calcium becomes more evenly distributed in the mitochondria. This mobilization of Ca can activate the phospholipases, which attach to the mitochondrial inner membranes, resulting in release of fatty acids and changes in membrane integrity that are apparently dependent on lipid protein interactions. These effects are initially reversible, although they are more severe in cases of subacute massive hepatitis with massive necrosis. The reactions proceed to the point where the mitochondria and cell membrane cannot self repair, even following removal of the injurious agent; this results in irreversible cell damage. It is concluded that the role of ion and water movements in the cytoplasm, with attendant sequential changes in organelle function is the key to understanding viral hepatitis.

3607 LIGHT MICROSCOPIC MORPHOLOGY OF VIRAL HEPATITIS. (Eng.) Ishak, K. G. (Armed Forces Inst. Pathology, Washington, DC 20306). *Am. J. Clin. Pathol.* 65(5):787-827; 1976.

The histopathology of acute and chronic infections associated with viral hepatitis is reviewed and illustrated with particular emphasis on the changes in chronic viral hepatitis. The various stages of uncomplicated and complicated viral hepatitis and its sequelae are discussed including: the active and subsiding phases of acute classic viral hepatitis, acute viral hepatitis with submassive necrosis or massive necrosis, acute cholestatic viral hepatitis, chronic hepatitis B antigen (HBAg) carrier, post hepatitis cirrhosis, chronic persistent viral hepatitis, active viral hepatitis, and cholestatic viral hepatitis. The i.v. drug abuser who has hepatitis is identified by the presence of particulate birefringent material (usually talc) in reticuloendothelial cells, as well as tissue eosinophilia. Ground glass hepatocytes are characteristic of the HBAg carrier. They may be present in chronic persistent and chronic active hepatitis and in cirrhotic livers with or without hepatocellular carcinoma. Ground glass cells, which contain the surface component of the HBAg, can be stained specifically by a number of stains including aldehyde fuchsin and orcein. The cirrhotic liver of the HBAg seropositive patient may show liver cell dysplasia, a premalignant change.

3608 A CORRELATION BETWEEN HISTOCOMPATIBILITY ANTIGENS HL-A 1 AND 8 AND IMPROVED DEFENSE AGAINST HEPATITIS B VIRUS IN PATIENTS WITH CHRONIC UREMIA. (Fre.) Jungers, P.; Descamps, B.; Zingraff, J.; Naret, C.; Bach, J. F. (Hopital Necker, 75015 Paris, France). *C. R. Acad. Sci. [D] (Paris)* 281(10):675-678; 1975.

Differences in the HL-A phenotypes of chronic uremic patients were investigated to determine their capacity to eliminate the hepatitis B antigen (HBsAg). Twenty-six histocompatibility antigens were studied (microlymphocytotoxicity and platelet complement fixation methods) in 328 chronic uremic patients who were treated by periodic hemodialysis; 201 were infected with the hepatitis B virus. HBsAg was detected at 2-3 month intervals by immunodiffusion, electroimmunodiffusion, passive hemagglutination, complement fixation, and radio-immunological tests. The only difference between patients with no HBs antigen (group 1, 127 patients), patients with persistent antigenemia (group 2, 154), and patients whose antigenemia disappeared after a few months (group 3, 47) was a significantly higher incidence of the phenotypes HL-A 1 (36.2%) and HL-A 8 (29.8%) in group 3 (HL-A 1,8, 23.4%) than in groups 1 and 2 (HL-A 1,8, 10.1 and 8.4%, resp.). The results suggest that an abnormally high frequency of the HL-A 1 and HL-A 8 association is characteristic of uremic patients who are capable of rapidly eliminating HBsAg.

3609 HISTOLOGICAL FEATURES OF CHOLESTASIS IN ACUTE AND CHRONIC HEPATITIS. (Fre.) Paliard, P.; Grimaud, J.-A. (Hopital E.-Herriot, Place Arsonval, F 69003 Lyon, France). *Arch. Fr. Mal. App. Dig.* 64(4):359-368; 1975.

The histological aspects of cholestasis in chronic and acute hepatitis are examined. Cholestasis is almost always present in acute common hepatitis, but it is moderate and has no particular characteristics; in pure or predominant acute cholestatic hepatitis, the cholestasis is more pronounced and constitutes the major lesion. In chronic hepatitis, cholestasis is inconsistent and is only accessory. The relations between cholestasis and alterations of the ductuli and septal canals are still hypothetical, since the changes are found in both cholestatic and noncholestatic forms; in addition, intralobular cholestatic lesions can be observed in both common acute hepatitis and acute cholestatic hepatitis. The only difference is the greater discretion of the cellular lesions in the latter form. It is suggested that the physiopathology of cholestasis is responsible for quantitative and qualitative alterations of the bile that are produced by hepatocytes involved in a pathological process originating from the cholestatic syndrome.

3610 BIOETHICAL QUESTIONS RELATED TO HEPATITIS B ANTIGEN. (Eng.) Blumberg, B. S. (Fox Chase Cancer Center, Philadelphia, PA 19111). *Am. J. Clin. Pathol.* 65(5):848-853; 1976.

Bioethical questions related to hepatitis B antigen carriers are discussed. The routine testing of blood donors for hepatitis B antigen (HBsAg) places carriers of hepatitis in a class different from that of other carriers (e.g., *Staphylococcus* and typhoid simply because they are identified). The bioethical problems, which derive from identification of such carriers, are viewed as a conflict between public health interests and individual liberty. The problems raised by person-to-person transmission are particularly difficult. The extent of hazards to the public is presently unclear, since it is not possible to distinguish carriers who transmit disease from those who do not. If all carriers are treated as infectious, the hazards imposed on them may be enormous (e.g., loss of job; inability to continue in the same profession, particularly the health sciences; restrictions on family and social contacts; etc.). It is suggested that the risk of transmitting hepatitis by person-to-person contact must be very small for a very large number of carriers. It is also suggested that until more is known about this situation all carriers should not be classed into the same stigmatized group.

3611 COMMON-SOURCE EPIDEMIC OF HEPATITIS DUE TO GLAZED AND ICED PASTRIES. (Eng.) Schoenbaum, S. C.; Baker, O.; Jezek, Z. (Dept. Medicine, Peter Bent Brigham Hosp., Boston, MA). *Am. J. Epidemiol.* 104(1):74-80; 1976.

Epidemiological studies that allowed the common source of a large outbreak of 61 cases of hepatitis to be identified and characterized are described. The highest attack rates were for persons 10-19 yr of age. The rate for boys was almost twice as high as for girls. Seventy percent of the cases involved school children, mainly from the public, as opposed to the parochial school, and most children were above grade 6. A virus was suspected and the dates of exposure were determined. The source was established as the local bakery where many public school children spent lunch breaks. Elementary school children and children attending the parochial school were not allowed to leave the school grounds at lunch time. Usually, there were twice as many boys as girls in the shop and they also ate twice as much. The source of infection was determined to be the icing or glaze on the baked products. The icing was spread on the baked goods by hand, and the doughnuts were hand dipped into the glaze; both processes occurred after all baking was completed. Whatever remained of the glaze or icing at the end of the day was stored for continued use and was mixed in with a fresh batch on the following day, thus allowing any contamination to remain active for a longer period. During the exposure period, the baker's assistant visited a physician, complaining of vomiting and a cold. He continued to work until a definite diagnosis of hepatitis was rendered. The source of the virus (feces, urine, blood, or saliva being the most likely) is not known. The data suggest that either certain persons or persons at certain stages of hepatitis may excrete a very large dose of virus concentrated in a very small amount of material.

3612 THE PREVALENCE OF HEPATITIS B SURFACE ANTIGEN IN COMMERCIALLY PREPARED PLASMA PRODUCTS. (Eng.) Hoofnagle, J. H.; Gerety, R. J.; Thiel, J.; Barker, L. F. (Bureau Biologics, Food Drug Admin., 8800 Rockville Pike, Bethesda, MD 20014). *J. Lab. Clin. Med.* 88(1):102-113; 1976.

Commercially available lots of plasma derivatives prepared between 1957 and 1975 were tested by radioimmunoassay for hepatitis B surface antigen (HBsAg). In all, 69% of lots of plasma protein fraction, 40% of factor IX concentrate, 20% of normal serum albumin, 13% of antihemophilic factor, 3% of fibrinogen, and 0.7% of immune serum globulin lots tested were HBsAg-positive. There was great variation in the prevalence of HBsAg-positive lots of each product among the different manufacturers, reflecting not only differences in methods of processing plasma, but also differences in donor populations. Those manufacturers relying upon volunteer donor plasma or placental source material demonstrated lower rates of HBsAg-positive lots of final products than those relying upon commercial donor plasma. There was a marked decrease in the prevalence of positive lots between 1971 and 1973, coincident with the onset of routine plasma donor screening for HBsAg. However, current requirements for plasma screening have not resulted in totally HBsAg-free plasma products. It is suggested that more sensitive and more reliable tests for HBsAg will probably reduce contamination of plasma pools with HBsAg to undetectable levels. However, despite HBsAg-status, the "high-risk" plasma products (fibrinogen, antihemophilic factor, and factor IX concentrate) must still be considered capable of transmitting hepatitis and must be used only with the strictest indication.

3613 AN ASSOCIATION OF HEPATITIS B (AUSTRALIA) ANTIGEN WITH PLATELETS. (Eng.) Furukawa, T.; Millman, I.; London, W. T. (Fox Chase Cancer Center, 7701 Burholme Ave., Philadelphia, PA). *Vox Sang.* 29(6):411-417; 1975.

Radioimmunoassay techniques were used to detect hepatitis B surface antigen (HBsAg) in individual cellular elements of blood from HBsAg carriers. HBsAg was not detected in erythrocytes, lymphocytes, or granulocytes. HBsAg was present in the platelet lysate, but not in the second and third platelet washes, suggesting that it was closely associated with platelets. HBsAg can become closely associated with platelets either through adsorption of particles to the cell membrane or by phagocytosis of the antigen. There are some data in support of the latter possibility. If platelets do phagocytize HBsAg particles, they may provide safety from immune attack for the infectious agent of hepatitis B and would thus allow the hepatitis B agent to travel from the point of entrance in the body to the liver or other organs. Studies of platelets incubated with fluorescine-labeled anti-HBsAg did not reveal significant staining of either surface or internal components. Electron microscopy did not reveal HBsAg-coated particles on the surface of the platelets. The results demonstrate an affinity between HBsAg and platelets, and suggest the possibility that HBsAg is phagocytized by the platelets. If the platelets do phagocytize HBsAg particles they might provide protection from immune attack for the infectious agent of hepatitis B and could be the means by which this agent travels from the point of entrance to other organs (e.g., liver) in the body.

3614 SERIAL LIVER BIOPSY OBSERVATIONS IN HEPATITIS B ANTIGEN CARRIERS BY LIGHT AND ELECTRON MICROSCOPY. (Eng.) Sun, S.-C.; Beasley, R. P.; Anderson, K. E.; Berg, H. S.; Hsu, C.-P.; Lee, W.-C. (Veterans General Hosp., U.S. Naval Medical Res. Unit No. 2, Taipei, Taiwan, Republic of China). *Am. J. Dig. Dis.* 21(5):366-369; 1976.

Liver morphology and function were restudied in 21 Chinese men with hepatitis B antigen (HBsAg) after an interval of 1.5-2 yr. Antigenemia and mild liver histopathology disappeared in one individual who developed antibody to HBsAg (anti-HBsAg). Twenty subjects who were chronic carriers of HBsAg had mild histological abnormalities that were usually persistent and were more commonly lobular than portal. Particularly striking were focal necrosis, eosinophilic bodies, ground-glass cytoplasmic change, and by electron microscopy, microtubular structures within cytoplasmic membranous cysternae. Interval development of chronic aggressive hepatitis was observed in only one subject. It is suggested that the great majority of HBsAg carriers have a good prognosis, at least over a 1.5-to 2-yr period, and that liver biopsy is most indicated in those patients with persistent liver function abnormalities.

3615 e ANTIGEN AND ANTI-e IN HBsAg CARRIERS. (Eng.) Feinman, S. V.; Berris, B.; Sinclair, J. C.; Wrobel, D. M.; Murphy, B. L.; Maynard, J. E. (Mt. Sinai Hosp., 600 University Ave., Toronto M5G 1X5, Ontario, Canada). *Lancet* 2(7946):1173-1174; 1975.

To assess the clinical significance of a new antigen/antibody system, "e" antigen and "anti-e," the presence of this antigen and antibody was correlated with the clinical status, SGPT levels, and liver histology of 70 hepatitis B surface antigen (HBsAg) carriers. Thirty-one carriers had liver biopsies. Thirty-two carriers had anti-e, and two had e antigen. Twenty-eight of 55 carriers with normal SGPT levels and 4 of 15 patients with raised SGPT had anti-e; this difference was not statistically significant. Two patients with e had raised SGPT levels. All patients with normal histology, 45% of patients with mild histological liver changes (i.e., lobular focal infiltrates with a very mild degree of infiltration in the portal tracts), and 23% of patients with striking histological liver changes (heavy portal infiltrates with additional lobular focal infiltrations) had anti-e; this association was statistically significant ($p<0.05$). The two patients with e antigen had the most severe abnormalities in liver function and histology. Since the patients with anti-e had been e-antigen positive at one point and subsequently seroconverted, it is likely that any predisposition to hepatic chronicity associated with e antigen must be related to long-term persistence of this determinant and not to short-term positivity. Indirect support for this assertion derives from the inverse relation found between frequency of anti-e and severity of liver dysfunction. A higher frequency of anti-e in patients with normal liver histology suggests that for those persisting hepatitis B infections in which the e determinant is measurable, anti-e seroconversion may predict the likelihood of a normal liver.

LIVER AND BILIARY TRACT

Chronic Hepatitis

3639 PREDNISONE FOR CHRONIC ACTIVE LIVER DISEASE: DOSE TITRATION, STANDARD DOSE, AND COMBINATION WITH AZATHIOPRINE COMPARED. (Eng.) Summerskill, W. H. J.; Korman, M. G.; Ammon, V. H.; Baggenstoss, A. H. (Mayo Clinic, Rochester, MN 55901). *Gut* 16(11):876-883; 1975.

The effects of prednisone (Pred), titrated by a standard mechanism, on the resolution of symptoms, abnormal liver function tests, and histological features of liver disease activity were investigated in 120 patients with chronic active liver disease (CALD). Patients who were treated with either maintenance doses of 20 mg Pred daily, with titrated doses given on alternate days (Pred-Titrad), or with a combination of 10 mg Pred and 50 mg azathioprine daily (Comb) survived, and their clinical and biochemical disease features were resolved more often than a control group receiving placebo or 100 mg azathioprine daily. The majority of patients treated with Pred or Comb entered full remission; remission occurred less often in the control group ($p<0.005$), and death occurred more frequently ($p<0.005$) than those receiving other therapies. In the Pred-Titrad patients, disappearance of histological features of active liver disease occurred less frequently ($p<0.005$) and remission was not more common than in the control group. The incidence of remission with Pred-Titrad was significantly and progressively less at each 6-month interval after 1 yr ($p<0.001$-0.005) through 36 months of follow-up. Histological remission occurred significantly more often with Pred and Comb than with other regimens (major side effects of therapy were commoner with Pred than with Comb or Pred-Titrad ($p<0.001$, for both). It is concluded that Comb is the initial treatment of choice for patients with CALD, since clinical, biochemical, and histological resolution of disease activity occurs as often as with Pred, while early side effects are significantly less frequent.

3640 FUNCTIONAL STATE OF THE MYOCARDIUM IN PATIENTS WITH CHRONIC HEPATITIS AND LIVER CIRRHOSIS UNDER ACUTE STROPHANTIN STIMULATION. (Rus.) Ol'binskaia, L. I.; Kitaeva, I. T.; Gorbatenko, V. P.; Ignatova, N. V. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Kardiologiia* 15(11):82-87; 1975.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

3641 ETHANOL METABOLISM IN LIVER CIRRHOSIS AND CHRONIC ALCOHOLISM. (Eng.) da Cruz, A. G.; Correia, J. P.; Menezes, L. (Hospital Escolar Sta.-Maria, Lissabon 4/Portugal). *Acta Hepato-gastroenterol.* 22(6):369-374; 1975.

Ethanol metabolism and its influence on the serum lactate/pyruvate ratio was studied in 17 patients. Ethanol (0.75 g) was injected i.v. in four controls, five alcoholics with cirrhosis, four non-alcoholic cirrhotics, and four alcoholics without liver disease. All refrained from the use of alcohol and drugs 4 weeks prior to the experiment. After maximal ethanol blood levels were achieved at the end of the infusion, ethanol removal occurred at two different rates. This was probably due to the fact that different volumes of ethanol were distributed with time: a fast period (30-60 min) and a slow period (60-180 min). The rates of disappearance in the two periods were similar in all groups, suggesting that liver cirrhosis, independent of clinical severity and/or chronic alcoholism with previous abstinence from alcohol, does not modify ethanol metabolic rates in the liver. The relation of lactate/pyruvate doubled in all cases, but it occurred within 30 min in the groups without liver disease and within 60 min in the cirrhotics. It is suggested that this accounts for the decreased occurrence of alcohol hypoglycemia found in cirrhotic patients.

3642 THE CLINICAL VALUE OF ASCITIC FLUID CULTURE AND LEUKOCYTE COUNT STUDIES IN ALCOHOLIC CIRRHOSIS. (Eng.) Kline, M. M.; McCallum, R. W.; Guth, P. H. (Wadsworth Hosp. Center, Los Angeles, CA). *Gastroenterology* 70(3):408-412; 1976.

A prospective study of peritoneal fluid culture and WBC findings was undertaken in 63 male patients with alcoholic cirrhosis and ascites to establish an acceptable leukocyte count in sterile ascites. The average total ascitic WBC count in sterile ascites was 404 cells/mm^3, with a range of 28-1800; 50% of the patients had greater than 300 WBC/mm^3. The mean percentage of polymorphonuclear (PMN) leukocytes was 43%, with a range of 2-98% and 53% were in excess of 25%. Five patients with spontaneous bacterial peritonitis (SBP), proven by positive cultures, had an ascitic SBP count range of 300-6320 WBC/mm^3 and a PMN leukocyte range of 20-76%. Physical findings did not allow clear separation of the two groups. Anaerobic organisms were not found. The majority of the patients had advanced alcoholic liver disease and were often severely ill as evidenced by an in-hospital mortality of 17%. The severity of illness, as characterized by fever, abdominal pain, hepatic tenderness, encephalopathy, and mortality, was not correlated with an increased ascitic WBC count. It is concluded that the differentiation of SBP from sterile ascites relies on prompt ascitic fluid bacteriology and that the increased survival rate of 40% of SBP patients in this study may be related to increased awareness of the problem and to early treatment.

3643 ALCOHOLIC HEPATITIS SUPERIMPOSED ON CIRRHOSIS. CLINICAL SIGNIFICANCE AND EFFECT OF LONG-TERM PREDNISONE TREATMENT. (Eng.) Schlichting, P.; Juhl, E.; Poulsen, H.; Winkel, P.; et al. (Kommunehospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(3):305-312; 1976.

The effect of long term prednisone treatment of patients with biopsy-verified alcoholic hepatitis superimposed on cirrhosis was investigated to determine the correlation between the morphological and clinical syndrome of alcoholic hepatitis. Of 483 patients with biopsy-verified cirrhosis, 99 had alcoholic hepatitis as defined by morphological criteria in the initial biopsy. Prednisone was given in an initial dose of 40 mg/day followed after 1-2 months by a maintenance dose of 10-15 mg/day. The maximum period of observation, per patient, ranged from 5-12 yr. In a comparison of clinical, biochemical, serological, and morphological features, male sex ($p<0.01$), alcoholism ($p<0.01$), vascular spiders ($p<0.05$), parotid enlargement ($p<0.05$), and white finger nails ($p<0.05$) predominated in patients with alcoholic hepatitis, whereas the frequency of patients with positive ANA and AGCT was higher among patients without alcoholic hepatitis. These differences disappeared when the comparison was confined to patients with admitted alcoholism. Daily consumption of alcohol was found in 82 of the 99 patients with morphological alcoholic hepatitis, 63 patients having a daily consumption of more than 50 g ethanol and 19 patients consuming less than 50 g daily. The survival of prednisone treated patients (median survival time 38 months), placebo treated patients (median survival time 34 months), and alcoholic hepatitis patients did not differ significantly. This was also true for each of the two subgroups comprising mild and severe cases, resp. It is concluded that in the majority of patients with morphologically diagnosed alcoholic hepatitis, prednisone treatment does not have any significant effect on survival.

3644 STUDIES ON THE SERUM LIPID AND LIPOPROTEINS IN STEATOSIS OF THE LIVER. (Eng.) Hilden, M.; Clausen, J. (Bispebjerg Hosp., Copenhagen, Denmark). *Acta Med. Scand.* 198(3):207-212; 1975.

Forty-five patients (33 men and 12 women) with steatosis of the liver were examined for serum lipid abnormalities. Twenty-eight patients were chronic alcoholics. Annual check-ups, including liver biopsy, were made to evaluate the development of the steatosis. The patients did not receive treatment with drugs or diet. Thirteen patients showed hypercholesterolemia, 16 increased serum triglyceride, and 8 increased serum phosphorus lipid. Two showed a type I lipoprotein anomaly, and 33 a type H-like pattern (increased β-lipoprotein, but normal serum cholesterol). Type II lipoprotein anomaly (increased β-lipoprotein associated with increase of serum cholesterol was found in four cases. Three had a type III and three had a type IV abnormal pattern, with increased pre-β-lipoprotein and serum triglyceride levels. There was a linear relation between the serum triglyceride levels and the percentage of the pre-β-lipoprotein ($p \leq 0.001$) and between serum triglyceride levels and serum free fatty acid levels ($r=0.95$). The slope of this regression line differed significantly from zero ($p \leq 0.001$). However, the slope of the regression line, showing the serum free fatty acid level as a function of the percentage of the pre-β-lipoprotein, was also significantly different from zero ($p \leq 0.001$) but the correlation coefficient was only $\overline{0}.69$. It is concluded that in cases where hepatic steatosis is related to alcoholism, a correlation exists between high serum free fatty acids, serum triglycerides, and to some extent, serum pre-β-lipoproteins. Although alcohol is known to stimulate triglyceride synthesis, alcoholism associated with steatosis hepatis is not associated with Frederickson lipoprotein type IV abnormality.

3645 EXPERIMENTAL AND CLINICAL STUDY ON FATTY ELIMINATION OF COENZYME A OF THE FATTY LIVER. (Ger.) Ohmori, S.; Hirayama, Y.; Iwamura, K. (Medizinische Klinik, Tokai Universitat, 259-11 Isehara, Bohseidai, Kanagawa, Japan). *Keio J. Med.* 24(3):219-240; 1975.

Cirrhosis

3648 CLASSIFICATION OF CIRRHOSIS. (Eng.) Galambos, J. T. (69 Butler St., S.E., Atlanta, GA 30303). *Am. J. Gastroenterol.* 64(6): 437-451; 1975.

The new classification of cirrhosis based on concepts of the pathology, pathogenesis, and clinical manifestations of the disease is presented. Cirrhosis was classified in 1974 according to morphologic and etiologic criteria. Morphologic classification includes micronodular cirrhosis, macronodular cirrhosis, and incomplete septal (multilobular) cirrhosis. The etiologic classification includes: cirrhosis of genetic disorders such as galactosemia, glycogen storage disease, tyrosinosis, hereditary fructose intolerance, alpha$_1$-antitrypsin deficiency, thalassemia, Wilson's disease, iron overload, incomplete biliary cirrhosis following cystic fibrosis, hereditary hemorrhagic telangiectasia, and abeltalipoproteinemia; chemical cirrhosis following predictable or nonpredictable toxic injury; alcoholic cirrhosis; infectious cirrhosis such as cirrhosis of viral hepatitis, congenital syphilis, and parasitic infections; nutritional cirrhosis after intestinal bypass operation for obesity; secondary biliary cirrhosis; congestive cirrhosis; cryptogenic cirrhosis; primary biliary cirrhosis; Indian childhood cirrhosis; and sarcoid cirrhosis. The authors conclude that this new classification scheme improves the understanding of the clinical-pathological correlations associated with various subgroups of human cirrhosis.

3649 CHANGES OF FREE AND TOTAL THYROXINE IN PATIENTS WITH LIVER CIRRHOSIS. (Pol.) Gembicki, M.; Dzieciuchowicz, S.; Sowinski, J.; Makowska, K.; Klincewicz, H. (60-355 Poznan, ul. Przybyszewskiego 49, Klinika Endokfrynologii, Poland). *Pol. Arch. Med. Wewn.* 54(2):141-146; 1975.

Total thyroxine concentration in serum (T_4), triiodothyronine-binding index (T_3I), free thyroxine by the dialysis method (DFT_4), free thyroxine index (FT_4I), and absolute value of free thyroxine ($ADFT_4$) were determined in 11 patients with compensated liver cirrhosis and in 10 patients with uncompensated cirrhosis. Statistically significant increases in T_3I, DFT_4, $ADFT_4$, and FT_4I were observed only in the uncompensated cirrhotics. It is concluded that these changes develop not as a result of excessive production of thyroid hormones but as a result of disturbances in the binding capacity of proteins that bind thyroid hormones, and as a result of impaired degradation of these hormones.

3650 CONCENTRATIONS OF AMINO ACIDS IN THE BLOOD OF DIFFERENT VESSELS OF PATIENTS WITH CIRRHOSIS OF THE LIVER DURING AND AFTER THE INTRODUCTION OF A PORTACAVAL ANASTOMOSIS. (Ger.) Breuer, J.; Breuer, H. (Institut fur Klinische Biochemie der Universitat Bonn, 5300 Bonn-Venusberg, W. Germany). *Z. Klin. Chem. Klin. Biochem.* 13(5):191-196; 1975.

Amino acid concentrations were measured by ion exchange chromatography in serum taken from various vessels during and after the performance of a portocaval anastomosis in patients with liver cirrhosis. In three female and eight male patients, amino acids were determined during surgery in samples taken from the following vessels (n=number of blood samples): arm vein (n=8), arteria femoralis (n=2), vena cava (n=7), vena portae (n=9), and aorta abdominalis (n=5). With exception of ornithine (aorta abdominalis versus vena cava), no statistically significant differences in the concentrations of amino acids were observed in the various blood vessels. One to three yr after the introduction of the portocaval shunt, amino acid concentrations were measured in blood from the arm vein and arteria femoralis in four female and five male patients. The concentrations of glutamic acid, phenylalanine, and lysine were significantly higher in blood from the arm vein than in blood from the arteria femoralis. The concentration of valine, leucine, and isoleucine were markedly lower in patients with liver cirrhosis than in normal subjects. It is concluded that portacaval anastomosis does not exert a noticeable effect on the metabolism of amino acids in patients with liver cirrhosis.

3651 USE OF A MILK AND CHEESE DIET IN TREATMENT OF ENCEPHALOPATHIES AS A RESULT OF PORTACAVAL SHUNT SURGERY AND CIRRHOSIS. (Fre.) Paccalin, J.; Cubanel, M.; Lantuit, P.; Traissac, F. J. (Hopital Saint-Andre, F-33000 Bordeaux, France). *Z. Ernaehrungswiss.* 14(2):113-124; 1975.

The effect of a 2,500-calories/day diet, which excluded protein from sources other than milk, cheese or vegetables, was studied in 38 alcoholic patients. Of the 38 patients, 11 had portacaval shunts, 6 were anorectic and hypertensive, and 21 had encephalopathic symptoms related to the cirrhosis (E.P.C.). The central nervous system (CNS) symptoms included alterations in sleep patterns, mood and character changes through confusion and disorientation to agitation, and a precoma state. Ammoniemia was usually present; however, there was little correlation between serum ammonia levels and clinical signs. Respiratory alkalosis, with pH above 7.45, was a symptom in the E.P.C. cases. The diet had a beneficial effect, and CNS symptoms disappeared within 17 days in the 11 cases with portacaval shunts and in 16 of 21 cases with E.P.C. The diet had a variable effect on the cirrhosis, but in some cases appetite returned, ascites receded, and hemorrhagic syndrome improved. Improvement of cirrhosis did not necessarily correlate with regression of encephalopathy or decrease in blood ammonia levels. It is concluded that diet be followed and in cases of cirrhosis, with and without E.P.C., and E.P.C., resulting from portacaval shunt surgery.

3652 PORTOSYSTEMIC SHUNTING IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS: A GOOD RISK DISEASE. (Eng.) Bauer, J. J.; Gelernt, I. M.; Kreel, I. (Mount Sinai Hosp., 100th St. and 5th Ave., New York, NY 10029). *Ann. Surg.* 183(3):324-328; 1976.

The results of portosystemic shunting procedures in five patients with primary biliary cirrhosis were compared with the results of 45 shunts performed in 42 patients with other types of cirrhosis (Laennec's, post-necrotic, schistosomal, biliary, or sarcoid). The case reports of the five patients with primary biliary cirrhosis are presented. Three of the five procedures performed for variceal bleeding were emergencies, and two were elective. There was no operative mortality; all patients were followed until the present or until death. One patient is alive 4 yr and another is alive 2 yr postoperatively. One patient died 4 yr after operation, and another died 16 months postoperatively. Another patient survived for 8 yr following her shunt and eventually died as a result of a cerebrovascular accident. The larger group of patients underwent portosystemic shunting because of portal hypertension secondary to other forms of liver disease. The operative mortality for the 20 shunt procedures performed on patients with Laennec's cirrhosis was 30%, while it was 10% in 20 procedures on patients with post-necrotic cirrhosis. There was no operative mortality in the five remaining patients with one of the three other types of cirrhosis. The absence of operative mortality in the patients with primary biliary cirrhosis and the fact that several of these patients had moderately long postoperative survival despite apparently poor liver function suggest that the usual criteria for assessing operative risk are not valid in primary biliary cirrhosis.

Gallbladder and Biliary Tract Diseases

3665 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY: PROBLEMS IN INTERPRETATION. (Eng.)

Kittredge, R. D.; Baer, J. W. (St. Luke's Hosp., 421 West 113th St., New York, NY 10025). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):35-46; 1975.

Problems in interpreting percutaneous transhepatic cholangiography are reviewed in 10 patients presenting with jaundice. Diagnoses included carcinoma of the head of the pancreas (2), choledocholithiasis (2), and one case each of carcinoma of the ampulla of Vater, multifocal sclerosing fibrosis, carcinoma of the gallbladder, diffuse adenocarcinoma of the liver, carcinoid of the duodenum involving the ampulla, and a granular cell myoblastoma obstructing the cystic duct and partially obstructing the common duct. Liver function tests revealed elevated levels of bilirubin, alkaline phosphatase, amylase, LDH, and SGOT. In some cases, the inability of the contrast material to filter through dense inspissated bile down to the true site of the block caused problems. In such cases, extensive aspiration is suggested. In diagnosing choledocholithiases, the picture appears either as defects due to the actual stones or as areas of narrowing secondary to trauma to the ductal system. Single or multiple localized narrowings of the biliary system may be caused by various diseases. Gastrointestinal series should always precede a percutaneous transhepatic cholangiogram, as biliary disease is often secondary to primary gastrointestinal pathology. Benign tumor of the common duct, inflammatory disease, secondary effects of calculi in the biliary tree, and multifocal fibrosclerosis must all be considered in the differential diagnosis of what may appear as a relatively benign, smooth, narrowed area of the biliary system. Failure to visualize the biliary tree by puncture is viewed as a technical failure from which no reliable information or assumptions may be drawn. In identifying the site of the block, additional procedures may be helpful, particularly selective visceral angiography. Percutaneous transhepatic cholangiography is the single examination capable of preventing unnecessary exploration of a jaundiced patient with primary liver parenchymal disease, and it is the most useful source of information if laparotomy becomes necessary to correct biliary tract obstruction.

3666 EVALUATION OF PEROPERATIVE CHOLANGIOGRAPHY DURING CHOLECYSTECTOMY. (Eng.)

Zimmermann-Nielsen, C.; Dyreborg, U.; Madsen, C. M. (Odense Univ. Hosp., Odense, Denmark). *Acta Chir. Scand.* 141(6):526-531; 1975.

The indications for exploration of the common duct, and the diagnostic reliability of postexplorative cholangiography were evaluated in a retrospective investigation comprising 219 choledochotomies, of which 57 were explorative and 162 were choledocholithotomies. Explorative choledochotomy was justified in 40 out of 57 cases, unless the risk of overlooking stones in the bile ducts was to be increased. In the remainder of the cases it was a question of either misinterpretation or of nonevaluable cholangiograms. A diagnostic reliability of 93.6% was obtained in postexplorative cholangiography, making the incidence of residual stones at postoperative cholangiography 6.4%. The errors were due to either technically poor cholangiograms (4/14) or misinterpretations (10/14). Peroperative cholangiography is a most important aid in diagnosing stones in the bile ducts before as well after choledochotomy, but the results can presumably be improved by radiological expertise.

3667 GRAY SCALE ULTRASOUND DIAGNOSIS OF OBSTRUCTIVE BILIARY DISEASE. (Eng.)

Stone, L. B.; Ferrucci, J. T., Jr.; Warshaw, A. L.; Wittenberg, J.; Slutsky, M. (Massachusetts General Hosp., Boston, MA 02114). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):47-50; 1975.

The diagnosis of obstructive ectasia of intra- and extrahepatic biliary ducts by gray scale ultrasound technique is described in two patients. In the first patient ultrasound examination was performed to exclude associated pancreatic abnormality. It revealed a dilated common duct containing a large calculus. Intravenous cholangiography disclosed a 1 cm common duct stone. Ultrasound examination disclosed a distinct 3.5 cm cystic structure with sharply defined margins located in the hepatic parenchyma. The round transonic space, having the appearance of a dilated duct in cross-section, appeared more laterally placed than the usually observed gallbladder echo. In the second patient, an abdominal ultrasound examination indicated a large irregular solid mass in the head of the pancreas. In addition, well-defined small ductal structures were seen to occupy a significant portion of the right liver lobe. Obstructive jaundice and cholangitis secondary to carcinoma of the pancreas was diagnosed. This case clearly indicates that the degree of intrahepatic biliary ectasia does not have to be as extensive as noted in the prior example of a dilated common duct. Multiple small intrahepatic ducts were defined, ranging in size from 0.75 to 1.0 cm. It is concluded that solid and fluid filled intrahepatic structures can be clearly discriminated by gray scale ultrasound technique.

3668 THE SIGNIFICANCE OF LIPOPROTEIN X IN THE DIAGNOSIS OF OBSTRUCTIVE JAUNDICE: COMPARISON WITH OTHER BIOCHEMICAL TESTS. (Ger.)

Mayr, K. (Allgemeines Krankenhaus Wels/Osterreich, Zentrallaboratorium, A-4600 Wels, Grieskirchnerstr. 42, Austria). *Dtsch. Med. Wochenschr.* 100(43):2193-2197; 1975.

The reliability of lipoprotein X demonstration in the diagnosis of obstructive jaundice was tested in 660 patients (1,105 samples) and compared with other biochemical parameters. Groups of 100 patients, each with morphologically proven liver or biliary-tract disease, were analyzed to determine the frequency with which the lipoprotein X demonstration and biliary stasis coincided. No direct connection between hepatitis B antigen and lipoprotein X was shown. Total cholesterol concentration proved to be of no use in the differential diagnosis of jaundice, although in a series of cases with and without obstruction, the mean concentrations differed significantly. Intra- and extrahepatic causes of jaundice and their etiology could not be clarified merely by demonstrating the presence or absence of lipoprotein X. However, it was shown to be a simple and safe method for proving biliary stasis.

3669 CLINICAL MANAGEMENT OF ACUTE CHOLANGITIS.

(Eng.) Saharia, P. C.; Cameron, J. L. (Johns Hopkins Medical Inst., Baltimore, MD). *Surg. Gynecol. Obstet.* 142(3):369-372; 1976.

The treatment of 78 patients hospitalized for acute cholangitis was evaluated by determining predisposing factors, clinical symptoms, hospital course, bacteriologic findings, and clinical outcome. Forty-eight of these patients had common duct stones, and in one-third of these, the stones were considered to be primary common duct stones. Serum bilirubin levels were elevated more than 5 mg% in 41 patients, while in 30, the levels ranged from 1 to 5 mg%. Alkaline phosphatase levels were elevated in 66 of 72 patients. SGOT levels were normal in only 3 of 45 patients, between 20-100 units in 29 patients, and over 100 units in 13 patients. SGPT values were normal in 1 of 35 patients, between 20-100 units in 23 patients, and over 100 units in 11 patients. Serum amylase levels were elevated in 19 of 54 patients; in 6 patients, the amylase value was more than 1,000 Caraway units. Roentgenograms of the abdomen, taken in flat and upright positions, were normal in 44 of 52 patients. An intravenous cholangiogram was performed in 38 patients and it demonstrated a pathologic condition in the biliary tree in only 15, while the remaining 23 patients did not visualize the biliary tree. In 20 of 50 patients from whom blood cultures were obtained, the culture was positive. *Escherichia coli* and *Klebsiella* were the two most common organisms, being isolated in 17 cases. All the patients were treated with combinations of antibiotics. Aminoglycoside and penicillin are an appropriate combination. Laparotomy was not carried out for several days after admission in several cases. Eleven patients died, six of them from continuing or recurring sepsis; postmortem examination revealed a retained stone or an inadequately treated stricture. It is concluded that adequate diagnostic procedures (i.v. cholangiography, transhepatic cholangiography, or transduodenal cholangiography) are necessary prior to exploration.

3670 THE URGENCY OF DIAGNOSIS AND SURGICAL TREATMENT OF ACUTE SUPPURATIVE CHOLANGITIS.

(Eng.) Welch, J. P.; Donaldson, G. A. (Box 87-H, Womack Army Hosp., Fort Bragg, NC 28307). *Am. J. Surg.* 13(5):527-532; 1976.

A follow-up study (average 5.5 yr) of 20 patients with suppurative cholangitis, who were treated at the Massachusetts General Hospital between 1962-1970, was conducted to determine the course and outcome of the disease. Fifteen patients had acute obstructive suppurative cholangitis due to complete obstruction of the common duct, many with coma, hypotension, and positive blood cultures. A total of 60% were older than 70 yr and most had a history of biliary tract disease. Although most had jaundice, abdominal pain, and fever, clinical symptoms were variable. The diagnosis of cholangitis was made in only 30% of patients before autopsy or surgery. Eighteen patients had calculi in the common duct, and two had primary fibrosis of the ampulla. Fewer of the patients with acute obstructive suppurative cholangitis operated on less than 24 hr after admission or deterioration died (17%) than those operated on after some delay (67%). Most patients underwent common duct exploration, and four had a concomitant sphincterotomy. In one instance, cholecystostomy only was performed, and this patient died because of ongoing sepsis. The overall mortality was 40%; of those subjected to operation, 25% died in the hospital. Most deaths occurred in seriously ill patients in whom surgical exploration was delayed from 48-72 hr. Recovery was dramatic in the 12 surviving patients, and calculous disease did not recur, except in two patients with retained stones. Prophylactic cholecystectomy is recommended to prevent the occurrence of this subtle and highly dangerous syndrome.

3671 IDEAL CHOLECYSTECTOMY: IN AN EARLY STAGE AT AN EARLY AGE.

(Eng.) van der Linden, W.; Sunzel, H. (Dept. Surgery, Centrallasarettet, Ostersund and Lasarette, Varberg, Sweden). *Acta Chir. Scand.* 142(1):62-66; 1976.

Two consecutive series of patients operated on for gallstone disease were compared to determine the effect of therapeutical approach on disease characteristics. One series (A) was from a hospital with an active surgical policy, while the other (C) was from a hospital with a conservative attitude about surgery. When subjected to the X^2 test, the conservative hospital had more cases of jaundice ($p>0.01$), more patients with high fever (equal to or greater than 39°), more patients with common duct and hepatic duct stones ($p<0.01$), more patients with hepatic duct stones ($p<0.01$), more cases of protracted fever ($0.05>p>0.01$), more cases of postoperative complications ($p<0.01$), and longer hospital stays. The older patients (over 60 yr) had a large influence on test results. Although hospital A serves an older population, it is concluded that gallstone patients in the area are operated on at an earlier age. It is also concluded that the ideal treatment for gallstone disease is early operation, i.e., operation at an early stage and at an early age.

3672 DAILY FLUCTUATION OF LITHOGENICITY IN BILE IN THE POSTOPERATIVE PERIOD IN CHOLECYSTECTOMIZED PATIENTS.

(Eng.) Massarrat, S.; Kumpel, W. (Medizinische Universitats-Poliklinik D-3550 Marburg/Lahn, W. Germany). *Res. Exp. Med.* 166(3):201-207; 1975.

The fluctuation of lithogenicity in bile samples taken at 4-to 5-hr intervals over 14 hr (7 AM to 9 PM) on 2 consecutive days was measured in seven freshly cholecystectomized patients on the 7th-9th days postoperatively. In four of the patients, the effect of meal intake on bile composition was studied in samples taken 1 and 2 hr after lunch. Daily fluctuations were observed. Lithogenicity in the bile started to increase 2 hr after lunch and peaked at 16 hr with a lithogenic index of 1.54, a high value compared with values in bile taken before breakfast (1.03) and lunch (0.90). These findings were different from those reported by other workers in earlier studies. The difference in study populations may account for the different findings. The fact that one patient lost bile through the T-tube in the first days after surgery and that five patients had gallstones in the main bile ducts may have influenced the type of diurnal fluctuations even though the enterohepatic circulation in these patients was largely intact 1 day before and during the study. Whatever the cause of this daily fluctuation of lithogenicity, it must be taken into consideration.

3673 EFFECTS OF ORAL CONTRACEPTIVES ON THE GALLBLADDER BILE OF NORMAL WOMEN. (Eng.) Bennion, L. J.; Ginsberg, R. L.; Garnick, M. B.; Bennett, P. H. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, 4212 N. 16th St., Phoenix, AZ 85016). *N. Engl. J. Med.* 294(4):189-192; 1976.

The effects of contraceptive steroids on the lipid composition of gallbladder bile were studied in 22 healthy women. Each subject was studied during routine use of oral contraceptives and also during normal menstrual cycles on no medication. Gallbladder bile was significantly more saturated with cholesterol during contraceptive therapy than during normal menstrual cycling (125% versus 92%, $p<0.001$). Chenodeoxycholic acid accounted for a significantly smaller proportion (35% versus 42%, $p<0.001$) and cholic acid a significantly greater r proportion (50% versus 41%, $p<0.001$) of total bile acids during contraceptive steroid therapy. These findings indicate that exogenous sex steroids in doses and formulations routinely prescribed induce important alterations in the composition of human gallbladder bile, and suggest a biochemical basis for the increase in gallbladder disease observed among women using oral contraceptives.

3674 THE SECRETION AND COMPOSITION OF LIVER BILE. (Pol.) Kuska, J. (Instytut Chorob Wewnetrznych Slaskiej Akademii Medycznej, 40-027 Katowice, Francuska 20, Poland). *Postepy Hig. Med. Dosw.* 29(4):515-536; 1975.

GENERAL

3735 IN VITRO SYNTHESIS OF IMMUNOGLOBULINS, SECRETORY COMPONENT, COMPLEMENT AND LYSOZYME BY HUMAN GASTROINTESTINAL TISSUES. II. PATHOLOGICAL TISSUES. (Eng.) McClelland, D. B. L.; Shearman, D. J. C.; Lai A Fat, R. F. M.; Van Furth, R. (Dept. Therapeutics, Univ. Edinburgh, Edinburgh, Scotland). *Clin. Exp. Immunol.* 23(1):20-27; 1976.

The possible demonstration of alterations in the synthesis of specific proteins by the gut mucosa was studied in a variety of gastrointestinal disorders. An *in vitro* culture technique was used to study protein synthesis in biopsies of human gastrointestinal mucosa obtained at endoscopy or surgery from patients with biliary gastritis, atrophic gastritis, peptic ulcer, gastric cancer, celiac diseases, Crohn's disease, or ulcerative colitis. The most striking disturbance in immunoglobulin (Ig) synthesis in the stomach occurred in patients who had marked bile reflux and severe gastritis, seen at endoscopy and confirmed by histology, indicating a gastritis with a marked inflammatory infiltrate. Increased IgA synthesis was not found in treated or untreated celiac disease. In dermatitis herpetiformis, slight increases in IgG and IgM synthesis in jejunal biopsies were noted. In Crohn's disease, IgG synthesis was increased in the inflamed tissue. Studies of lysozyme and complement synthesis in small bowel mucosa did not indicate marked differences from normal. In active ulcerative colitis, there was an increased mucosal synthesis of IgG, in comparison with normal rectal biopsies, and these returned to near normal in patients who were in remission. The significance of the increased local immunoglobulin synthesis and its relation to the pathogenesis of the diseases studied are not known.

3736 SYNTHESIS OF IMMUNOGLOBULIN AND SECRETORY COMPONENT BY GASTROINTESTINAL MUCOSA IN PATIENTS WITH HYPOGAMMAGLOBULINAEMIA OR IgA DEFICIENCY.

(Eng.) McClelland, D. B. L.; Shearman, D. J. C.; Van Furth, R. (Royal Infirmary, Edinburgh, Scotland). *Clin. Exp. Immunol.* 25(1):103-111; 1976.

Biopsies of intestinal mucosa from five patients with adult hypogammaglobulinemia and from three patients with selective immunoglobulin (Ig) A deficiency were studied to determine their ability to synthesize Ig's and secretory component (SC). Tissue fragments were cultured *in vitro* in medium containing ^{14}C-labeled amino acids, and newly synthesized proteins were detected by radio-immunoelectrophoresis. Synthesis of IgA, and in some cases of IgG and IgM, was found in intestinal mucosal biopsies from hypogammaglobulinemics and IgA deficient subjects. Free secretory component synthesis was found in cultures from all of the patients. Labeling of the IgA-SC was not detectable in any of the cultures from the hypogammaglobulinemic patients, and it was weakly visible in cultures from two of the three IgA deficient subjects. The lack of detectable IgA-SC synthesis contrasts with the findings in cultures of normal intestinal mucosa in which labeling of both free SC and IgA-SC lines was observed. Tissue sections of these biopsies, studied by immunofluorescence, demonstrated immunoglobulin bearing cells. Many cells had the morphology of plasma cells, but some had a more lymphocyte-like appearance with a thin layer of fluorescing cytoplasm. The findings demonstrate that immunoglobulin synthesizing cells are present in the intestinal mucosa of immunoglobulin deficient individuals. Local immunoglobulin synthesis may explain partially why these patients do not often have major problems with intestinal infections.

3737 SELECTIVE ARTERIAL EMBOLIZATION FOR CONTROL OF MASSIVE UPPER GASTROINTESTINAL BLEEDING.

(Eng.) Reuter, S. R.; Chuang, V. P.; Bree, R. L. (Dept. Radiology, Wayne County General Hosp., Eloise, MI 48132). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):119-126; 1975.

The use of selective embolization of the bleeding artery was evaluated in 15 patients with massive upper gastrointestinal bleeding. Successful control of the bleeding was achieved in 11 of the 15 patients. In nine patients in whom control was immediate, the nasogastric return changed from bright red to pink to almost clear over a 5-to 15-min period. Of these 11 patients, 9 were still alive and well 2-18 months after embolization. One patient died of pneumonia, unrelated to the bleeding, 11 months after embolization. The other patient had no bleeding for 2 weeks, but then a repeat massive hemorrhage was caused by hemorrhagic gastritis. Of the four patients who were not controlled, one had a large gastric ulcer eroding into a major branch of the left gastric artery and exsanguinated in 20 hr. The other three, who had diffuse hemorrhagic gastritis, died of complications secondary to gastric surgery 1 month following embolization. Follow-up angiograms were done in five patients receiving Amicar clot, in two receiving Gelfoam, in one receiving Oxycel, and in one receiving fat emboli. Most of the previously occluded branches were again patent but no active bleeding was seen in all patients receiving Amicar-mixed blood clot. In patients receiving Gelfoam and Oxycel, the entire left gastric artery was thrombosed at the second examination, indicating that clot had propagated proximally from the site of the occlusion. The patient receiving fat emboli fell between the two extremes with a few branches open, but most occluded. Preliminary results from these studies are encouraging.

3738 SELECTIVE INTRAARTERIAL INFUSION OF VASOPRESSIN FOR CONTROL OF GASTROINTESTINAL BLEEDING: EXPERIENCE WITH 35 CASES.

(Eng.) Melson, G. L.; Geisse, G.; Stanley, R. J. (Washington Univ. Sch. Medicine, 510 S. Kingshighway, St. Louis, MO 63110). *Gastrointest. Radiol.* 1(1):59-65; 1976.

Experience with intra-arterial infusion of vasopressin to control 35 episodes of variceal and arterial gastrointestinal bleeding in 32 patients is presented. Active bleeding was from esophageal varices in 11 cases and from an arterial site in 22 (stomach, 11; duodenum, 1; jejunum, 2; colon, 7; and liver, 1), including a jejunal diverticulum and a colonic ulcer in Bechet's disease. Two patients, not actively bleeding, were infused for portal decompression before an elective mesocaval shunt. Active bleeding was controlled by the infusion of 0.2 or 0.3 U/min vasopressin (15 min-70 hr), in 64% of patients with variceal hemorrhage and in 59% of those with arterial sources. There were no significant complications directly attributable to this therapy. It is concluded that selective intra-arterial vasopressin infusion is an effective and relatively safe therapy for gastrointestinal hemorrhage from a variety of lesions.

3739 IMMUNOSTIMULATION WITH INTRAPERITONEALLY ADMINISTERED BACILLE CALMETTE GUERIN FOR ADVANCED MALIGNANT TUMORS OF THE GASTROINTESTINAL TRACT.

(Eng.) Falk, R. E.; MacGregor, A. B.; Landi, S.; Ambus, U.; Langer, B. (Dept. Surgery, Univ. Toronto, Canada). *Surg. Gynecol. Obstet.* 142(3):363-368; 1976.

Thirty-five patients treated with i.p. bacille Calmette Guerin (BCG) and then given intermittent systemic chemotherapy and p.o. boosters of BCG were studied to determine the most effective route of administration for nonspecific immunostimulating bacterial antigens. Two treatment schedules were followed. Schedule one called for 2 mg BCG, i.p. followed 5 weeks later by 120 mg BCG p.o.; during weeks 6, 7, and 8, 0.75-1.0 g fluorouracil, i.v., were administered. The latter portion of the treatment was repeated in four week cycles. Schedule two called for 2 mg BCG, i.p., followed, on day 14, by 1 g fluorouracil and 1-2 g cyclophosphamide, i.v., and on day 18 by 120 mg BCG p.o. Treatment given on days

14 and 18 was repeated at monthly intervals. Eight patients had carcinoma of the stomach with a mean survival of 11 months from time of diagnosis and 9.4 months from start of BCG treatment. Three patients are still alive, two with no progression of disease. Eight patients had carcinoma of the pancreas or biliary system. The mean survival time for this group was 14.4 months. Two are still alive but have evidence of disease progression. Nineteen patients had carcinomas of the colon with metastases. Of these 19, 9 had metastases to the liver and 6 of these 9 remain alive, with a mean survival time of 12.8 months for the survivors and 13.2 months over-all for the group. This represents an improved survival time over that of literature controls. The i.p. administration of BCG was followed by a brisk, febrile reaction from which the patient recovered within 2-5 days. A low grade peritoneal reaction persisted with low grade fever and malaise in some patients, particularly in those with previous marked hypersensitivity to tuberculin. Treatment for 1 week with 300 mg daily of isoniazid relieved the peritonitis. It is concluded that the combination of i.p. BCG followed by p.o. administration and cytotoxic drugs increased survival time in this consecutive series of patients when compared to historical controls. Response was most marked in patients with metastases to the liver from primary carcinoma of the colon.

3740 ROLE OF TOXIGENIC AND INVASIVE BACTERIA IN ACUTE DIARRHEA OF CHILDHOOD. (Eng.)

Guerrant, R. L.; Moore, R. A.; Kirschenfeld, P. M.; Sande, M. A. (Univ. Virginia Sch. Medicine, Charlottesville, VA 22901). *N. Engl. J. Med.* 293(12): 567-573; 1975.

The cause of acute diarrhea was investigated in 40 infants and children by examining stools for fecal leukocytes. A potential etiologic agent was identified in the stools of 31 patients (77.5%). In 20 of these, only toxigenic organisms were isolated. Toxigenic strains of *Escherichia coli* were serotyped from 19 patients. Seven had both toxigenic and invasive *E. coli* or salmonella isolated, and four had only invasive pathogens. Nineteen patients showed fecal leukocytes, which were predominantly polymorphonuclear. Leukocytes were found in 9 of the 11 with invasive organisms, whereas only 4 of 20 with toxigenic strains, alone, had fecal leukocytes. Of nine patients without a demonstrable pathogen in their stools, six had fecal leukocytes, suggesting an invasive process. All 27 patients with toxigenic organisms isolated had organisms that produced heat-labile cholera-like toxin. Three patients had *E. coli* that also produced a heat-stabile toxin. No organisms, which produced heat-labile toxin or tissue invasion, were observed in 20 controls. However, there was one *E. coli* that produced only heat-stable toxin and one salmonella. Chinese-hamster-ovary cell assay demonstrated that the stronger the response to the assay, the greater the toxin concentration. This response was reduced in a step-wise fashion by serial dilution. The observation that the toxin-producing capacity of the organisms varied from strain to strain was confirmed in the rabbit-ileal-loop assay. When tested in the guinea pig-conjunctivitis model to determine the ability of these strains to cause tissue invasion, nine *E. coli* strains caused inflammatory conjunctivitis. Seven of the patients who had these strains had fecal leukocytes. When testing four of the five strains of salmonella, two produced tissue invasion and both were from patients with fecal leukocytes. Of the six patients in this series with temperatures over 39.4 C, five had salmonella, heavy parasitic infestation or fecal leukocytes, indicating an invasive bowel process. It is concluded that in this pediatric population, *E. coli* appears to cause most acute diarrheas due to toxigenic and invasive pathogenic mechanisms.

3741 INFANTILE GASTROENTERITIS: A CLINICAL STUDY OF REOVIRUS-LIKE AGENT INFECTION.

(Eng.) Shepherd, R. W.; Truslow, S.; Walker-Smith, J. A.; Darnell, R.; Barker, C. M. (Queen Elizabeth Hosp. Children, Hackney Road, London E2 8PS, England) *Lancet* 2(7944):1082-1084; 1975.

A clinical study was conducted in 32 infants with symptoms from infections with the human reovirus-like agent (RLA). RLA was identified by electron microscopy of fecal extracts. A fairly consistent clinical pattern was found in 30 patients who had a gastroenteritis-like illness. The disease was usually mild, affecting mainly infants of less than 2 yr and males more commonly than females. The incubation period appeared to be 48-72 hr; the onset was sudden, often with vomiting during the first 1-2 days of illness. Loose yellow-green offensive stools without blood or mucus developed after variable time periods, and there was often accompanying fever. Severe dehydration and electrolyte imbalance were uncommon, and with standard treatment the illness was uncomplicated, usually lasting 5-8 days. These features resemble those of previously reported winter epidemics of infantile nonbacterial gastroenteritis and it is suggested that these epidemics were due to RLA. Two infants in whom RLA was identified in the stool did not have a gastroenteritis-like illness although both had protracted diarrhea. It is suggested that this is a result of persistent virus excretion in some infants with delayed recovery following acute gastroenteritis.

3742 VIRAL GASTROENTERITIS INDUCED BY THE HAWAII AGENT: JEJUNAL HISTOPATHOLOGY AND SEROLOGIC RESPONSE.

(Eng.) Dolin, R.; Levy, A. G.; Wyatt, R. G.; Thornhill, T. S.; Gardner, J. D. (Natl. Inst. Allergy Infectious Diseases, LCI, Building 1D, Room 11N-214, Bethesda, MD 20014). *Am. J. Med.* 59(6):761-768; 1975.

Peroral jejunal biopsies were performed in seven normal subjects prior to, 48 hr after, and 2 weeks after the administration of the Hawaii agent of viral gastroenteritis (4.3-5.0 cm^3). Light and electron microscopic examination revealed an intact mucosa with blunted villi, shortened and distorted microvilli, swollen mitochondria, and intercellular edema. These histologic changes were seen only in acutely ill subjects and were absent 2 weeks after illness in three of four who were previously ill. This reversible lesion was similar to, but not identical with, that previously described in viral gastroenteritis induced by the Norwalk agent. Serum antibody increases in response to the Hawaii agent, as measured by immune electron microscopy, were present in three of the four ill subjects and in none of the three who remained well. These studies indicate that infection with the Hawaii agent of viral gastroenteritis can result in reversible histologic lesions in the jejunal mucosa, which are temporally associated with the development of clinical illness, and which are accompanied by serum antibody rises to the Hawaii particle.

3743 THE GARDNER SYNDROME: A STUDY IN CELL CULTURE. (Eng.) Danes, B. S. (Cornell Univ. Medical Coll., New York, NY 10021). *Cancer* 36(6):2327-2333; 1975.

Experiments were conducted to investigate the existence of a cell marker for the presence of the gene responsible for the Gardner syndrome. Tetraploidy was increased in skin fibroblast cultures derived from 3 probands with the Gardner syndrome and from 9 affected members of 1 family as compared to that occurring in cultures from 5 unaffected family members as well as from 6 relatives by marriage and from 15 normals grown in the laboratory at the same time under the same conditions (Eagle's minimum essential medium containing 20% human AB serum, and 5% beef embryo extract ultrafiltrate; pH 7.0-7.4). Tetraploidy was present at the first subculture (2 weeks after the initial biopsy was cultured) and for each line studied, the percentage of dividing cells showing tetraploidy remained constant. Increased occurrence of tetraploidy was not observed in skin fibroblast cultures from patients with the genetic disorders: familial polyposis coli (2 probands and 1 family member), familial osteomas (1 proband), and familial fibromatosis (neurofibromatosis, 2 probands), each of which show one of the four abnormal tissue growths observed in the Gardner syndrome. The relation of the observed tetraploidy to the increased risk of such patients to develop abnormal growths and cancer has not been established. The increased tetraploidy should be of value in identifying the presence of the gene for the Gardner syndrome in high risk families.

3744 MAGNESIUM ABSORPTION IN THE HUMAN SMALL INTESTINE. RESULTS IN NORMAL SUBJECTS, PATIENTS WITH CHRONIC RENAL DISEASE, AND PATIENTS WITH ABSORPTIVE HYPERCALCIURIA. (Eng.) Brannan, P. G.; Vergne-Marini, P.; Pak, C. Y. C.; Hull, A. R.; Fordtran, J. S. (Univ. Texas Health Science Center, Dallas, TX 75235). *J. Clin. Invest.* 57(6):1412-1418; 1976.

Magnesium (Mg) absorption was investigated in the jejunum and ileum of 14 healthy volunteers, through *in vivo* intestinal perfusion studies. Test solutions contained from 0 to 20 mM Mg in the form of $MgCl_2$. The rate of absorption in the jejunum increased progressively as luminal Mg concentrations increased, with a tendency toward saturation at the higher concentrations. Kinetics and rates of Mg absorption in the ileum were comparable to those in the jejunum. The only exception was that at higher luminal concentrations, the ileal absorptive process was fully saturated. Calcium had little or no influence on Mg absorption, even though it was noted that Mg decreased calcium absorption to a limited degree. Patients with a reduced rate of calcium absorption in end-stage renal disease had a severely depressed Mg absorption. However, patients with absorptive hypercalciuria and nephrolithiasis showed increased rates of calcium absorption and had normal absorption of Mg. It is suggested that Mg absorption in the human is mediated by a transport process, which is different from that which facilitates calcium absorption. Also, normal Mg absorption may be dependent upon vitamin D. It was not established whether the normal intestine can absorb Mg against an electrochemical gradient. As the experiments did not contain glucose or other nutrients, and since they were designed to result in near zero movement in water, the results may not be directly applicable to normal physiological conditions within the gastrointestinal tract.

3745 GASTROINTESTINAL TUBERCULOSIS. (Eng.) Wales, J. M.; Mumtaz, H.; MacLeod, W. M. (Wessex Cardiac and Thoracic Center, Oakley Road, Southampton, England). *Br. J. Dis. Chest* 70(1): 39-57; 1976.

Case reports of 14 patients with gastrointestinal tuberculosis are presented. No pathognomic features were revealed either on history or by examination. The differential diagnoses included carcinoma of the colon, appendicitis, amebiasis, actinomycosis, ulcerative colitis, and granulomatous bowel disease. Primary ileocecal tuberculosis, with no evidence of other disease, was noted in only two patients. In a single case, a positive culture from the gut was obtained and the human bacillus was isolated. Eleven of the patients had positive sputum culture, and in each case the human organism was isolated. *Mycobacterium tuberculosis* was isolated in a case where there was extensive pulmonary disease; a negative culture in the presence of isolated gut disease was misleading in one patient. Concomitant pulmonary disease was noted in 12 patients; chest radiographs showed extensive changes consistent with tuberculosis usually of the fibrocaseous type with or without cavitation in 10 of them. It is suggested that radiological appearance of contrast studies of the gut often suggest, but seldom diagnose tuberculosis. Changes resulted from inflammatory masses, thickening of the bowel wall, ulcers, and fistulas. The tuberculin reaction was positive by the Heaf multiple puncture technique or the Mantoux reaction in eight patients. In five cases, serious complications due to stricture formation were noted. Five patients were treated with corticosteroids, and no adverse effects were noted in four of them; in addition, there was no evidence of further stricture formation during healing. It is concluded that surgical treatment is necessary for strictures, perforations, and obstruction.

3746 VASCULITIS WITH HEPATITIS B ANTIGENEMIA: LONG-TERM OBSERVATIONS IN NINE PATIENTS. (Eng.) Sergent, J. S.; Lockshin, M. D.; Christian, C. L.; Gocke, D. J. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *Medicine* 55(1):1-18; 1976.

Nine biopsy proven cases of hepatitis B-associated necrotizing vasculitis are reported. Of the nine patients, three died of vasculitis, one died of chronic hepatitis several years after sustaining permanent neurological debility from vasculitis, and five are still surviving. Of the survivors, only one is currently symptom-free, two have residual neurological deficits, one of whom has chronic active liver disease, and two have residual hypertension, one of whom is azotemic. All survivors have remained hepatitis B antigen positive. The fact that these patients had liver disease separated them from patients with generalized vasculitis who were hepatitis B antigen negative. No relation was found between the appearance of the vasculitis and the liver disease. The activity of the vasculitis was unrelated to the activity of the hepatitis. Vasculitis was always transient, of a few months duration, and never recurred, even though liver disease progressed in some patients. The pathogenesis of this disease is not clear, but it is suspected that circulating complexes of hepatitis B antigen and antibody are pathogenic in this syndrome.

3747 THE VALUE OF A HISTAMINE H_2-RECEPTOR ANTAGONIST IN THE MANAGEMENT OF PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Richardson, C. T.; Walsh, J. H. (Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX 75235). *N. Engl. J. Med.* 294(3):133-135; 1976.

Inhibition of acid secretion by metiamide was assessed in three patients with the Zollinger-Ellison syndrome. Metiamide (200 or 300 mg), administered by nasogastric tube, inhibited acid secretion transiently (2.5 hr) by 85-100% in all patients. Although anticholinergic drugs, alone, inhibited acid secretion by only 0-35% in these patients, the combination of metiamide and anticholinergic markedly prolonged the inhibitory effect of metiamide. Total gastrectomy was refused by one patient, and was impossible in another; both were treated with metiamide and anticholinergic for 5 and 10 months, resp. A third patient was treated with metiamide and anticholinergic for 3 weeks in preparation for total gastrectomy. Ulcer pain and diarrhea disappeared, and all gained weight. It is concluded that H_2-receptor antagonists may be useful in the treatment of some patients with the Zollinger-Ellison syndrome.

3748 EXOCRINE PANCREATIC FUNCTION IN MAN AFTER CYTOTOXIC TREATMENT. (Eng.) Fleischer, K.; Meckel, H. (Medical Clinic Univ. Wurzburg, 87 Wurzburg, Josef-Scheider-Weg 2, Germany). *Acta Hepatogastroenterol. (Stuttg.)* 22(6):392-398; 1975.

The function of the exocrine pancreas was studied in patients with malignant disease, before and after massive dose therapy with cyclophosphamide and before and after combined cytotoxic treatment. Patients were studied using the secretin-pancreozymin test and were divided into four groups, depending upon the type of therapy and the conduct of the examination. In group I, four patients received a single massive dose of 30-40 mg/kg cyclophosphamide. In group II, two patients received 2.5 mg/kg procarbazine p.o. for 2 weeks, 0.03 mg/kg vincristine i.v. on days 1 and 8, and 15 mg/kg cyclophosphamide on days 2 and 9. In group III, five patients received oral doses of cyclophosphamide totaling 6-55 g for 2-18 months. In group IV, four patients were given 172-1,689 mg busulfan for 3-57 months. In the patients on massive dose or continued therapy with cyclophosphamide, the volume of the duodenal secretion and the bicarbonate, electrolyte, and enzyme outputs in the duodenal secretion remained essentially unchanged. In contrast, cytotoxic combination treatment resulted in decreased activities of amylase and lipase, and in some cases of trypsin. After maintenance treatment with busulfan, a reduction of the trypsin and amylase activities was detectable; chymotrypsin and lipase were slightly lowered. In these studies, there is no evidence of impaired exocrine pancreatic function in man following massive dose therapy or prolonged treatment with cyclophosphamide.

3749 SOME CHANGES OF THE CANALICULAR CELLS IN PANCREAS WITH DILATED ACINI. (Eng.) Gonzalez Cueto, D. M.; Olmedo, G. S.; Naveiro, J. J. (Hospital Ramos Mejia, Urquiza 609, Buenos Aires, Argentina). *Medicina (B. Aires)* 35(4):407-415; 1975.

The percentage of pancreatic surface occupied by the canalicular cell mass over the total exocrine tissue was calculated in autopsy samples to determine whether the canaliculi increase in size in pancreas with dilated acini. This percentage was correlated with the number of dilated acini and the blood levels of urea (BUN) determined during the last 24 hr prior to death. The surface occupied by the canalicular cell mass had a positive correlation with the number of dilated acini and with the levels of BUN. However, the number of dilated acini did not correlate with the levels of BUN ($p>0.5$). Thus, the enlargement of the canalicular cell mass is an earlier and more frequent change than is the acinar dilatation in the pancreas of uremic patients. Acinar dilatation is due to dilatation of the intracinar portion of the canaliculi, which occurs as a final step of the cellular enlargement. The acinar cells do not participate in this process. Some alteration in the mechanism by which the canalicular cells share in the secretion of bicarbonate by the pancreas may trigger these histologic changes. This change may be related to metabolic acidosis.

Parasitology

3804 HUMORAL IMMUNITY OF PARASITIZED, MALNOURISHED CHILDREN. (Eng.) Purtilo, D. T.; Riggs, R. S.; Evans, R.; Neafie, R. C. (Univ. Massachusetts Medical Sch., 55 Lake Ave. North, Worcester, MA 01605). *Am. J. Trop. Med. Hyg.* 25(2):229-232; 1976.

The nutrition, intensity of parasitism, complete blood count, and serum immunoglobulin (Ig) concentration were determined in 63 children. The children were categorized according to their degree of malnutrition using the Gomez scale. The hemoglobin values were lower for the seven protein calorie malnutrition (PCM) groups (10.6 g/100 cm^3 and 10.4 g/100 cm^3) than for the normals (11.4 g/100 cm^3) and children with first degree PCM (11.2 g/100 cm^3). The average serum transferrin concentrations ranged from 328 mg/100 cm^3 for the first degree PCM group to 214 mg/100 cm^3 for the third degree PCM group. The differences in transferrin concentrations among groups were statistically significant ($p<0.01$). Moderate leukocytosis was present in 53 of the 63 subjects, the values ranging from 5,706/mm^3 to 28,900/mm^3. There was a significant correlation between the eosinophil count and the intensity of parasitism ($p=0.026$). The IgA and IgM concentrations were moderately increased; the IgG was increased threefold, and the IgE was markedly increased in concentration. The concentrations of the immunoglobulins were related significantly ($p=0.004$ IgA, $p=0.008$ IgE) to the intensity of parasitism. The results indicate that the concentrations of immunoglobulins, especially IgE, are significantly correlated with the intensity of parasitism by nematodes.

3805 IMMUNOLOGICAL STUDY ON MIGRATION OF ASCARIS INTO THE BILIARY TREE. (Eng.) Torisu, M.; Fukawa, M.; Harasaki, H.; Kitamura, K.; Kai, S.; Nagano, M.; Ikeda, S.; Hisatsugu, T.; Nishimura, M.; Dohy, H.; Baba, T.; Sonozaki, H. (Kyushu Univ. Sch. Medicine, Fukuoka 812, Japan). *Clin. Immunol. Immunopathol.* 4(4):467-477; 1975.

Immunological studies were performed on six patients with ascaris migration into the biliary tree. Studies were performed before and after surgical exploration of the biliary tree, using skin tests, complement fixation, and hemagglutination tests. Of these, the skin test, using purified ascaris antigen, was found to be the most sensitive. The serum immunoglobulin (Ig) E level was increased before the operation (3,300-9,440 mg/ml) in all six cases. After removal of the migrated ascaris at surgery, the serum IgE level decreased to normal range within 1 month. Prausnitz-Kustner reactions (P-K) were performed in eight healthy volunteers, using the patients' sera before and after the operation. Only sera from preoperative patients gave positive P-K reactions. These findings suggest that the preoperative increase in serum IgE is attributable to the ascaris infestation. The purified ascaris antigen was found to have a high chemotactic effect on eosinophils, even at concentrations of 0.1 γ/ml. The data confirm the presence of potent chemotactic activity in the body constituents of the worm. The previously described complement-derived or lymphocyte-derived chemotactic factors are secreted by the host, suggesting that the ascaris-derived eosinophil chemotactic factor differs from the other factors.

3806 SERUM ANTIBODIES AND JEJUNAL HISTOLOGY IN GIARDIASIS ASSOCIATED WITH MALABSORPTION. (Eng.) Ridley, M. J.; Ridley, D. S. (Hosp. Tropical Diseases, St. Pancras Way, London, NW1 OPE, England). *J. Clin. Pathol.* 29(1):30-34; 1976.

Possible antibody response to *Giardia lamblia* was studied in the sera of 70 patients with malabsorption, 2 patients with asymptomatic giardiasis, and 17 non-tropical patients used as controls. The indirect immunofluorescent test (IFT) results at a screening dilution of 1/10, using precyst antigen, showed that 32 of 36 patients with giardiasis and malabsorption were positive; none of the 17 controls was positive. Sera from 18 serologically positive patients were tested 1 month or more after treatment for giardiasis, and the IFT showed a decrease in 11 cases and no change in 8. In six of six giardiasis sera, the IFT antibody was immunoglobulin (Ig) G. Tests with IgA and IgM were negative. In a direct fluorescent test on cryostat sections of jejunum in 10 cases of giardiasis with a short history of about 1-month duration and moderately severe histologic change, plasma cells in the lamina propria showed increased fluorescence with the anti-IgM serum, in comparison with normal control jejunum. In the early stages of the infection, immunoglobulin production by plasma cells was predominantly IgM. Further tests suggest that although immunodeficiency may be associated with giardiasis, the latter is not necessarily the cause of an immunoglobulin deficiency. The histological changes of malabsorption in jejunal mucosa were graded from 0 to V. In the two patients with giardiasis without malabsorption, the jejunum was within normal histological limits, grade 0. In 36 patients with giardiasis and malabsorption, the histological grading was 0, I, or II in 4, 12, and 20 cases, resp. A rough correlation between antibody titer and the severity of the histological lesion in the jejunum was noted. In searching for yeasts in the centrifuge deposit of jejunal juice of the malabsorption patients, no association with giardiasis was found.

3807 MORBIDITY IN Schistosomiasis mansoni IN RELATION TO INTENSITY OF INFECTION: STUDY OF A COMMUNITY IN MACHAKOS, KENYA. (Eng.) Siongok, T. K. A.; Mahmoud, A. A. F.; Ouma, J. H.; Warren, K. S.; Muller, A. S.; Handa, A. K.; Houser, H. B. (Ministry of Health, Nairobi, Kenya). *Amer. J. Trop. Med. Hyg.* 25(2):273-284; 1976.

A cross-sectional study of the prevalence and intensity of *Schistosmiasis mansoni* was conducted on 83% of the population (416 individuals from 90 households) of the village of Lower Nduu, Machakos, Kenya. The findings were correlated with morbidity, as determined by standard medical examinations. The male:female ratio was 44:56 and more than 50% of the subjects were under 20 yr of age. Malaria was of very low endemicity in the area. The incidence of intestinal helminths and *Schistosoma haematobium* was also low. *S. mansoni* infection had an overall prevalence of 82%, with a peak of 98% in the 10-19 yr age group, and a decline to about 70% in the older population. With respect to intensity, 12% were uninfected, 28% had light infection, 21% had moderate infection, and 33% had severe infections. Extremely severe infections with egg counts of over 1,000/g of feces occurred in 16%. Females aged 10-14 yr showed peak intensity of 1,026 eggs/g and males showed peak intensity of 1,019 eggs/g at age 20-24 yr. Histories of weakness or inability to work occurred in only a small portion of the population and this was not correlated with the intensity of infection. More of the severely infected individuals suffered abdominal pain. Hepatomegaly was noted more often in those with severe infection, and splenomegaly occurred in 7% of those patients with egg counts of over 400/g. Hepatosplenomegaly was noted in almost 3% of the population studied; most of these patients were under 21 yr of age, and all were infected with *S. mansoni* (58% of them had high egg counts). Liver function tests were within normal limits for most of the patients. Two of the patients had esophageal varices, but these and seven others studied by splenoportography had patent portal veins. It is concluded that disease manifestations are observed largely in those persons with severe infection.

GENERAL

Regional Enteritis

3813 EXPERIMENTAL REGIONAL ENTERITIS IN PIGS. (Eng.) Kalima, T. V.; Saloniemi, H.; Rahko, T. (Helsinki Univ. Central Hosp., Helsinki 29, 00290 Finland). *Scand. J. Gastroenterol.* 11(4): 353-362; 1976.

To clarify the role of lymphatic obstruction in the pathogenesis of regional enteritis, the mesenterial lymphatics of the terminal ileum were obstructed in 21 pigs. Long-lasting obstruction was produced by injecting 4 ml of formalin into regional lymph nodes. The growth of the pigs was retarded; their ileum became reddish and edematous with numerous intra-abdominal adhesions and mucosal ulcerations. Eleven pigs developed fistulae; none had chylous ascites. Histologically, the subserosa was infiltrated by round and giant cells giving an impression of granulomatous inflammation. Many lymphatics were thrombosed, and the lymphoid tissue was hyperplastic. These changes became more prominent with extensive subserosal fibrosis after 3 weeks, when the edema diminished. Transmural inflammation with round cell aggregates was then the most typical feature. Purulent infection with crypt abscesses appeared near the fistulae. It is concluded that when the function of lymphatics is destroyed, the transport of particles, too large to enter blood vessels, is inhibited. This produces chronic irritation and edema with declining tissue nutrition and oxygenation, thus causing fibrosis. Moreover, the intestinal lumen is a source of infections, and the edematous tissue is easily infected. This may lead to mucosal ulcerations and, progressively, to fistulae.

3814 ABNORMALITIES IN THE APPARENTLY NORMAL BOWEL MUCOSA IN CROHN'S DISEASE. (Eng.) Goodman, M. J.; Skinner, J. M.; Truelove, S. C. (Dept. Medicine, Univ. Chicago, Chicago, IL 60637). *Lancet* 1(7954):275-278; 1976.

Rectal biopsy specimens from 13 patients who had Crohn's disease elsewhere in the bowel, but never in the rectum, were examined to determine plasma cell density, volume of lamina propria, and mucosal glucosamine synthetase activity. The difference in mean plasma cell density in the lamina propria between 13 patients with Crohn's disease and 23 controls (3,935 cells/1,000 points versus 906 cells/1,000 points, resp.) was highly significant ($p<0.001$). There was also a significant difference in the lamina propria volume increase ($p<0.001$) between Crohn's disease patients (124 points/100 intercepts of muscularis mucosa) as compared with controls (52 points/100 intercepts). The mean glucosamine-synthetase levels for the patients with Crohn's disease was 20.55 units, which was a highly significant elevation ($p<0.001$) above the normal mean of 13.91 units. It is suggested that the colonic mucosa is always abnormal in Crohn's disease, although it may appear to be normal on conventional histopathological examinations.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

9 IDENTIFICATION OF CHOLECYSTOKININ-SECRETING CELLS.

(Eng.) Polak, J. M.;
om, S. R.; Rayford, P. L.; Pearse, A. G. E.;
han, A. M. J.; Thompson, J. C. (Royal Postgraduate
ical Sch., Hammersmith Hosp., London, W12, U.K.).
cet 2(7943):1016-1018; 1975.

unocytochemical techniques and electron microscopy
semi-thin and serial thin sections were utilized
the identification of cholecystokinin (CCK)-pro-
ing cells in the mucosa of the upper small intes-
e of humans, dogs, and pigs. Fresh samples of
trointestinal mucosa (body and antrum of the
mach, duodenum, jejunum, ileum, and pancreas) were
ained. Part of the material was freeze-dried,
ined for endocrine granules, or stained by
direct immunofluorescence using antibodies raised
inst natural CCK and gastrin. The remaining
ples were prepared for immunohistochemistry or
ventional electron microscopy. There were many
ightly fluorescent cells specifically stained for
(in the duodenum and jejunum of all species inves-
gated. Gastrin-secreting cells (G cells) were
en in the antral and upper duodenal mucosa, but
ese cells were infrequent in the remainder of the
all intestine. Comparison of serial 1-μm resin-
bedded sections, stained with antibodies to CCK or
strin, showed that the two peptides were located in
fferent cells. The CCK cells were elongated or
ar shaped with an apical process reaching the
testinal lumen. Their secretory granules were
derately electron dense, with an average diameter
250 nm and a closely attached membrane, making
em similar to the I granules of the modified
esbaden classification. The combination of these
chniques provides a simple and reliable method of
entifying CCK cells in gastrointestinal mucosa.

20 EFFECT OF POSTRADIATION BLEEDING ON PROLIFERATIVE ACTIVITY OF CELLS IN SMALL
TESTINE CRYPTS OF RATS.

(Eng.) Petrovic, N. V.
oris Kidric Inst. Nuclear Sciences, Vinca, Yugo-
avia). *Strahlentherapie* 150(6):585-589; 1975.

e effect of postradiation bleeding on the dynamics
duodenal crypt cell proliferation was studied in
-month-old female rats weighing 170 to 180 g. The
imals were exposed to 800 R (115 R/min) irradia-
ion, immediately after which they were bled by
rdiac puncture to 50% of total blood volume.
rmal animals and animals that had been only bled
only irradiated were used as controls. The
tathmokinetic index of normal rats was 270.6 ± 16.5%.
the first day after irradiation, the indices were
41.5 ± 6.8% in the rats that underwent bleeding
nly and 155.0 ± 9.0% in the rats that underwent
rradiation only. On the third day, the values were
40.0 ± 22.5%, 323.0 ± 9.9%, and 137.0 ± 15.6% in
he bled only, irradiated only, and bled-plus-
rradiated rats, resp. On the fourth day, the
espective values were 195.0 ± 26.0%, 244.0 ± 18.0%,
and 270.0 ± 11.8%. By the fifth day, the indices for the bled and bled-plus-irradiated animals were 179.0 ± 4.6% and 282.0 ± 15.0%, resp. Three days after irradiation, the mean turnover time of duodenal crypt cells in the animals that were irradiated only was extended by over 60%; in irradiated-plus-bled and bled animals, the time was extended by 100%. On the fourth day, the turnover time in irradiated and irradiated-plus-bled animals was almost normal, but was still extended by 30% in the animals that were bled only; similar results were obtained on the fifth day. The results demonstrate that although there were no significant differences in proliferative activity of duodenal epithelial cells in irradiated-plus-bled animals and irradiated animals, the postradiation reparative process in irradiated-plus-bled animals is more stable. It is concluded that bleeding reduced the sensitivity of the epithelium to the radiation by its hypoxic activity; on the other hand, bleeding also removed the damaging agents that appeared as secondary products after total irradiation.

3821 QUANTITATIVE MICROSCOPIC EVALUATION OF THE ENDOPLASMIC RETICULUM IN DEVELOPING HUMAN LIVER.

(Eng.) de la Iglesia, F. A.; Sturgess, J. M.; McGuire, E. J.; Feuer, G. (Warner-Lambert Res. Inst., Sheridan Park, Mississauga, Ontario, 15K 1B4, Canada). *Am. J. Pathol.* 82(1):61-70; 1976.

Sixteen liver biopsies from children 2 months to 18 yr old were analyzed by sterology to study the composition and relative distribution of endoplasmic reticulum membranes within hepatocytes. The histologic aspects of the liver, as well as the clinical laboratory data of these patients, revealed no abnormalities when observed for suspected hepatic ailment. Morphometric analysis of four tissue blocks per biopsy was undertaken by means of combined light and electron microscopy using standard stereologic formulas. There was less endoplasmic reticulum in liver cells from children who were 2-9 months old. These low levels were accounted for by reduced surface of smooth membranes. There was a first-order relationship in the growth of smooth endoplasmic reticulum between 2 months and 4 yr at a rate of 17.1 cm^2/hr, similar to the membrane accumulation rate in experimental animals. Membrane dimensions from Golgi apparatus and rough endoplasmic reticulum were cell-size dependent, and these organelles matured within 2 months of postnatal life. These findings are significant because of the low amounts of smooth endoplasmic reticulum membranes present at an early age. This lack of membrane surface agrees with findings in developing liver of various species. Studies showed reduced membrane population and low microsome-bound enzyme activities, which under normal circumstances, allow the hepatocyte to undertake detoxification and drug metabolizing processes. Thus, the reduced membrane availability of the liver in infants may account for their inability to metabolize foreign compounds.

LIBRARY U. OF I.

3822 SCANNING ELECTRON MICROSCOPY OF MOUSE INTRAHEPATIC STRUCTURES. (Eng.) Nopanitaya, W.; Grisham, J. W. (Univ. North Carolina, Sch. Medicine, Chapel Hill, NC 27514). *Exp. Mol. Pathol.* 23(3):441-458; 1975.

The intrahepatic surface of normal Swiss albino mouse livers, which had been fixed *in situ* by perfusion with paraformaldehyde, was examined by scanning electron microscopy. By fracturing the fixed liver, surfaces of hepatocytes and sinusoidal endothelial cells were exposed; slicing the tissue revealed the internal structures of portal tracts. Hepatic plates were uniformly one cell thick and generally straight, while hepatocytes were polyhedral and sharply angulated. Sinusoids were round to oval in cross section, appearing to be tubes in their longitudinal aspect. Their largest diameter was 20-30 μm. Endothelial cell bodies contained numerous surface pits, which measured 0.05-0.1 μm in diameter. The thinned endothelial cytoplasm contained frequent, small, round fenestrations of about 0.1 μm in diameter, which formed clusters of up to 20 fenestrae. Hepatic arteries were distinguished from portal veins by their smaller size and thicker walls. Arterial endothelial cells were rectangular in shape, with their long axis oriented along the long axis of vessels. In contrast, venous endothelial cells were more nearly round or oval in shape, and were randomly oriented on the luminal surface. Arterial endothelial cell bodies were thicker and more elongated than venous endothelial cells. It is concluded that scanning electron microscopy is useful for the study of intrahepatic surface structures, and may allow further correlations to be made between hepatic structure and function in both healthy and disease states.

3823 ULTRAMICROSCOPIC INVESTIGATIONS OF THE EXOCRINE PANCREAS OF THE DOG AFTER VAGOTOMY. (Eng.) Putzke, H.-P.; Herzog, K. H. (Institut fur Allgemeine und Spezielle Pathologie der Universitat Rostock, DDR-25, Rostock, Strempelstrasse 14, E. Germany). *Exp. Pathol. (Jena)* 11(5/6):270-275; 1975.

The exocrine pancreas of 20 dogs was investigated by electron microscopy before and 3, 4, 10, 11, and 14 days after bilateral truncal vagotomy. Up to the 10th day of the experiment, a disturbance of the secretion of the acinar cells was found, with a sustained increase in enzyme protein synthesizing and lysosomal activity, irregular formation of zymogen granules, and probably continuous extrusion of the enzyme proteins. Distinct irregularities were seen in the formation of the zymogen granules. Numerous secretion granules were evident at all times, but between the 3rd and 10th days, they were frequently derounded or represented miniature forms of mature granules. On the 10th day, immature zymogen granules in the form of homogenous or, less frequently heterogeneous, prozymogen granules predominated. The few mature granules were mostly derounded or appeared as defective forms. On the 11th and 14th days, the zymogen granules were again formed regularly. On the 3rd and 4th days, the epithelial cells of the intercalary ducts showed a moderate hydropic swelling of the ground plasm and large cytoplasmic vacuoles with an inhomogenous content of low density. In addition, membraneously lined cytoplasmic inclusions can be found with partially digestively-changed cytoplasmic structures, which may represent lysosomes. The results show two deviations in the acinar cells, which may indicate a certain impairment of the secretion: an increased cytolysosomal activity and distinct irregularities in the formation of zymogen granules.

3824 POLYPLOIDY IN MOUSE LIVER AFTER REPEATED HEPATECTOMIES. (Rus.) Faktor, V. M.; Uryvaeva, I. V. (Inst. Developmental Biology, USSR Acad. Sciences, Moscow, USSR). *Tsitologiia* 17(8): 909-916; 1975.

3825 ENDOCRINE CELLS OF THE GASTROINTESTINAL TRACT IN NORMALCY AND PATHOLOGY. (Rus.) Aruin, L. I. (Inst. Medical Genetics, USSR Acad. Medical Sciences, Moscow, USSR). *Klin. Med. (Mosk.)* 53(1):41-45; 1975.

3826 IMMUNOCYTOCHEMICAL IDENTIFICATION OF GLUCAGON-SECRETING CELLS IN THE GASTRIC MUCOSA. (Fre.) Baetens, D.; Rufener, C.; Unger, H.; Renold, A. E.; Orci, L. (Institut d'Histologie et d'Embryologie, Ecole de Medecine, 1211 Geneva 4, Switzerland). *C. R. Acad. Sci.* [*D*] *(Paris)* 282(2):195-197; 1976.

3827 PLASMALEMMA OF HEPATOCYTES IN MICE OF DIFFERENT AGES: FINE STRUCTURAL STUDY AFTER ISOLATION; MEASUREMENT OF THE 5'-NUCLEOTIDASE ACTIVITY. (Fre.) Montmory, E.; Bourges, M. (Laboratoire d'Histologie-Embryologie-Cytogenetique, Faculte de Medecine, B.P. n^0 38, 63001 Clermont-Ferrand, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 281(18):1333-1336; 1975.

3828 PARTICLES ASSOCIATED WITH MICROVILLOUS BORDER OF INTESTINAL MUCOSA [Letter to Editor]. (Eng.) Chandler, R. L.; Bird, R. G.; Bland, A. P. (Inst. Research Animal Diseases, Compton, Newbury, Berks, England). *Lancet* 2(7943):931-932; 1975.

3829 TIME OF RENEWAL, PROLIFERATIVE POOL AND DURATION OF MITOTIC CYCLE OF THE COMMON BILE DUCT EPITHELIUM CELLS. (Rus.) Dyban, P. A. (Inst. Experimental Medicine, USSR Acad. Medical Sciences, Leningrad, USSR). *Biull. Eksp. Biol. Med.* 80(9):93-94; 1975.

3830 ELECTRON MICROSCOPE STUDIES OF Shigellae INTERACTION WITH CELL CULTURE. II. THE STRUCTURAL-FUNCTIONAL REACTION OF THE MAIN CYTOPLASMIC ORGANOIDS OF THE INFECTED CELL. (Rus.) Nosova, L. S.; Zhdanov, E. E.; Trofimova, M. N. (Inst. Epidemiology and Microbiology, Gorki, USSR). *Tsitologiia* 17(8):965-970; 1975.

3831 CYTOPLASMIC CISTERNS STRUCTURALLY ASSOCIATED WITH PLASMOLEMMA IN HEPATOCYTES OF DIFFERENT MICE STRAINS. (Rus.) Shkurupii, V. A. (Novosibirsk Medical Inst., Novosibirsk, USSR). *Tsitologiia* 17(8):985-987; 1975.

ABSORPTION - EXCRETION - TRANSPORT

3839 A METHOD FOR THE CONTINUOUS STUDY OF NET WATER TRANSPORT IN THE FELINE SMALL BOWEL. (Eng.) Jodal, M.; Hallback, D.-A.; Svanvik, J.; Lundgren, O. (Dept. Physiology, Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 95(4):441-447; 1975.

A new perfusion technique for the study of net water transport across the intestinal epithelium *in vivo* is described. The lumen of an isolated segment of feline small bowel is steadily perfused with a solution of known composition, in a closed perfusion system, with a reservoir large enough to prevent recirculation. The intestinal segment may be enclosed in a plethysmograph. Changes in the perfused volume are recorded by a volume transducer coupled to the recirculating system via a T-tube. If no motility occurs, the changes of the perfusion volume reflect net water transport across the intestinal epithelium. A quantitative comparison of this technique with the conventional polyethylene glycol method revealed no significant difference. The plethysmographic method also makes it possible to quantify the net water absorption via lymph and blood and to study bidirectional fluxes of water or other easily followed substances, by the addition of proper tracers.

3840 MUCOSAL IRON RETENTION AND PLASMA IRON ABSORPTION IN THE DUODENUM AND JEJUNUM OF DOGS. (Eng.) Christophersen, E. B.; Balcerzak, S. P. (Kirurgisk avdeling A, Rikshospitalet, Pilestredet 32, Oslo, Norway). *Scand. J. Gastroenterol.* 11(4):397-402; 1976.

To gain further information about iron absorption in the duodenum and jejunum, experiments employing ^{55}Fe and ^{59}Fe and a new, simplified surgical method for constructing temporary isolated intestinal segments were performed in dogs. Two groups of non-anemic dogs, one with normal tissue iron stores and one with decreased tissue iron stores, underwent the procedure. A nontraumatic vascular clamp was placed proximally across the duodenum distal to the point at which the biliary and pancreatic ducts enter the intestine. A second clamp was placed distally across the duodenum close to the ligament of Treitz. A segment of jejunum was then isolated in a similar fashion. The proximal portion of the jejunal segment was separated from the distal division of the duodenal segment by a distance of twice the length of the respective isolated segments. A double purse-string suture was placed on the antimesenteric border at the distal portion of the isolated duodenal and jejunal segments. A solution of 0.1 mg of ferrous sulfate and 1 mg of ascorbic acid was injected through silastic tubing into the lumen of each segment. The solution for the duodenal segment contained 30 µCi ^{59}Fe, and for the jejunal segment, 60 µCi ^{55}Fe. The solutions were left in the segments for 2.5 hr before washout. On the 14th postoperative day, ^{59}Fe and ^{55}Fe radioactivity per milliliter per RBC was measured, and iron uptake by segments was determined. In three dogs with normal iron stores in the bone marrow, liver, and spleen, the retained iron was slightly higher in the jejunum (mean, 10.8%) than in the duodenum (6.2%). In five dogs with decreased iron stores, the percentage of retention was always higher in the duodenum (25.1% in duodenum and 18.2% in jejunum), and the iron retained was about four times higher than in dogs with normal iron stores. This indicates that mucosal uptake of iron from the lumen and mucosal transfer of iron from plasma vary inversely with body iron stores, but compared to mucosal uptake, mucosal transfer is more restricted to the duodenum, more affected by body iron stores, more limited, and more crucial to regulation of iron absorption.

3841 RESISTANCE OF INTESTINAL TRIGLYCERIDE TRANSPORT CAPACITY IN THE RAT TO ADAPTATION TO ALTERED LUMINAL ENVIRONMENT.

(Eng.) Wu, A.-L.; Clark, S. B. (Massachusetts General Hosp., Boston, MA). *Am. J. Clin. Nutr.* 29(2):157-168; 1976.

The effects of altered luminal conditions on the relative capacities for [^{14}C]triolein transport through different regions of the intestinal wall were examined in male Wistar rats. The fat-releasing capacities of the proximal and distal small intestine were controlled by using substrate induction and surgical manipulation to alter the luminal environment *in vivo*. The regional mucosal lipid accumulation found after 3 hr of maximal steady-state triolein absorption was used as an index of the transmucosal lipid transport capacities of different regions of the intestine. The high ^{14}C-lipid accumulation in distal mucosa was not reduced after direct distal infusion of oleic acid and monolein (2:1, v/v) for 7 days before challenge. No decrease in distal intestinal lipid accumulation was found 1 month after removal of the proximal 40% of the intestine beyond the duodenum. Conversely, alteration of the luminal environment in the proximal intestine by 3 days of starvation or by ileal resection did not increase the tissue ^{14}C-lipid concentration in this region during maximal [^{14}C]triolein challenge. When proximal and distal segments were exchanged by jejuno-ileal transposition without reduction in intestinal length, major ^{14}C-lipid accumulation still occurred in originally-distal segments during [^{14}C]triolein infusion 1 month later. The triolein absorption rate was about 35% lower in animals receiving atropine infusions (0.24 mg/hr) than in controls ($p<0.01$). The results confirm that distal intestinal mucosa accumulates large amounts of triglyceride when exposed to high concentrations of fat in the lumen. An intrinsic difference may exist in the capacity for chylomicron synthesis or secretion by the proximal and distal intestine, at least in the rat.

3842 THE EFFECTS OF CORTICOSTERONE AND CORTISONE ON THE UPTAKE OF POLYVINYL PYRROLIDONE AND THE TRANSMISSION OF IMMUNOGLOBULIN G BY THE SMALL INTESTINE IN YOUNG RATS.

(Eng.) Morris, B.; Morris, R. (Dept. Zoology, Univ. Nottingham, Nottingham NG7 2RD, England). *J. Physiol. (Lond.)* 254(2):389-403; 1976.

The effects of 5 mg corticosterone and 5 mg cortisone on the uptake of polyvinyl pyrrolidone (PVP) and the transmission of immunoglobulin (Ig) by the small intestine were investigated in young Wistar rats. Rats underwent two surgical procedures: a ligature was tied around the pyloric sphincter and 0.1 ml of a labeled rat IgG (0.5 mg) preparation was injected into the duodenum distal to the ligature; and a ligature was tied 9-12 cm from the ileocecal junction and 0.1 ml of PVP preparation (20 mg/ml solution containing 0.25-0.5 µCi/^{125}I/ml) was injected into the gut distal to the ligature. The distribution of PVP along the intestinal lumen and in the intestinal wall, following p.o. administration to normal and corticosterone-treated rats, was extremely variable. Valid comparisons between the two groups of animals were not observed using this technique. Three, 4, and 5 days after corticosterone treatment, there was no significant change in the uptake of ^{125}I-labeled PVP from standard doses injected into ligated segments of the distal small intestine, nor did the treatment induce precocious replacement of the absorptive cells in this region. Cortisone-induced precocious cell replacement, a process that took up to 4 days to complete, also led to a marked reduction ($p<0.001$) in the uptake of ^{125}I-labeled PVP from ligated segments of the distal intestine. Three days after treatment with corticosterone (5 mg, i.p., at 12 days of age), there was a marked reduction ($p<0.001$) of labeled IgG transport into the blood. Four and 5 days after treatment, there was some recovery of the IgG transport function. Three days after treatment with cortisone, there was closure of the gut to labeled IgG. The results show that cortisone injection leads to a precocious change of cell type in the distal intestine and to a dramatic fall in PVP uptake.

3843 STIMULATION OF VITAMIN D-DEPENDENT Ca-ATPase AND OF INTESTINAL CALCIUM ABSORPTION BY DIPHENYLHYDANTOIN.

(Eng.) De Wolff, F. A. (Dept. Pharmacology, Univ. Leiden, Wassenaarseweg 72, Leiden, Netherlands). *Eur. J. Pharmacol.* 33: 71-79; 1975.

The effects of diphenylhydantoin (DPH) and ouabain were studied *in vitro* on Mg-ATPase, Ca-ATPase, and alkaline phosphatase (AlPase) in isolated brush borders from rat jejunum and *in vivo* on intestinal calcium absorption in vitamin D-deficient, D-repleted, and normal Wistar rats. In enzyme studies in isolated brush borders, Mg-ATPase was not significantly affected by vitamin D deficiency or DPH. Vitamin D repletion (1,000 IU vitamin D_3) of deficient animals enhanced Ca-ATPase activity by 100% ($p<0.001$) and partially restored AlPase activity. Concentrations of 10^{-4} M DPH had a highly stimulating effect on the activity of Ca-ATPase. In both deficient and repleted rats, this stimulation was 2.5 times that of controls ($p<0.01$). In one group of deficient and repleted rats, a large stimulation of Ca-ATPase activity was found following 10^{-3} M ouabain, but this effect could not be reproduced. In Ca *in vivo* absorption studies, repletion resulted in a significant enhancement of Ca absorption ($p<0.05$), which was most pronounced in the presence of DPH. Increased levels of Ca-absorption were significantly higher than in normal rats ($p<0.001$). The addition of 10^{-4} M DPH to the perfusion fluid resulted in a significant enhancement of Ca absorption in all three groups of animals ($p<0.005$). It is concluded that there is a striking parallel between Ca absorption and Ca-ATPase in response to vitamin D and to DPH. It is likely that Ca-ATPase and not AlPase is involved in the transport of Ca through the microvillous membrane, and that DPH enhances Ca absorption by activation of Ca-ATPase.

3844 EFFECTS OF NEOMYCIN ON SUGAR TRANSPORT IN THE SMALL INTESTINE OF RATS AND HAMSTERS. (Spa.) Rull, S.; Ponz, F. (Facultad Ciencias, Universidad Navarra, Pamplona, Spain). *Rev. Esp. Fisiol.* 30(3):183-190; 1974.

The effect of different concentrations of neomycin B (as a free base) on the intestinal absorption of sugars (in isotonic saline solution) was studied *in vivo* in adult, white Wistar rats and Syrian hamsters. The absorption of 2.77 mM galactose and 50 mM D-arabinose (evaluated as μM of sugars absorbed/cm of small intestine) in rats was significantly increased when neomycin (6 or 18 mM) was added to the sugar solutions, while a 6 mM solution of neomycin also increased the absorption of 2.77 mM glucose. The effects disappeared after washing the intestine with saline solution. The absorption of 2.77 mM glucose was significantly inhibited by 18 mM neomycin; this inhibition persisted after intestinal washing, probably indicating lasting cellular alterations induced by the higher concentration of neomycin. In small concentrations (0.8 and 1.5 mM), the neomycin had no effect on the absorption of glucose or galactose. Neomycin (18 mM) had no effect on the absorption of glucose in hamsters. *In vitro* experiments showed that neomycin (5 mM) had no significant effect on the active transport of glucose by everted intestinal villi of the rat or intestinal rings of the hamsters. Oxygen consumption by rat intestinal rings incubated for 60 min with or without 2.77 mM glucose was not affected by the presence of neomycin. Morphological changes, including marked desquamation, flattening of the intestinal villi, and inflammatory infiltration of the proper mucous membrane were observed in the intestinal epithelium of the rat, but not in that of the hamster. The authors conclude that the increased *in vivo* absorption of sugar in rats was caused by the action of neomycin, which increased the permeability of the luminal membrane regardless of the transport systems.

3845 THE EFFECTS OF REMOVAL OF SODIUM IONS FROM THE MUCOSAL SOLUTION ON SUGAR ABSORPTION BY RABBIT ILEUM. (Eng.) Naftalin, R. J.; Holman, G. D. (Dept. Physiology, Kings Coll., London, England). *Biochim. Biophys. Acta* 419(2):385-390; 1976.

The effects of mucosal deprivation of Na^+ on the absorption of labeled 3-*O*-methyl glucose at both high (20 mM) and low (2 mM) concentrations, and on D-galactose (2 mM) and β-methyl-D-glucose (1 mM) transport by sheets of New Zealand rabbit ileum were investigated. Fluxes of sugars were measured at intervals after addition of radioisotopes (^3H, ^{14}C) to a mucosal solution containing 140 mEq Na^+. The terminal ileum was dissected and stripped of its serosa and outer muscle layers before mounting as a flat sheet in the flux chambers. The removal of Na^+ from the mucosal solution alone caused a significant reduction in mucosal-serosal (m-s) flux of all sugars. The ratios of $^3H/^{14}C$-labeled sugar entering the tissue from the m-s solutions were all reduced by replacement of mucosal Na^+ by choline. Except in the case of 3-*O*-methyl glucose, removal of mucosal Na^+ increased the m-s sugar fluxes. Removal of Na^+ from both m-s solutions caused a further significant decrease in J_{ms} and net flux in all conditions, except with 3-*O*-methyl glucose, and reductions in tissue accumulation and the specific activity ratio occurred in all conditions. There was a further increase in m-s fluxes of ^{14}C-labeled sugars in all cases when Na^+ was removed from both serosal and mucosal solutions, compared with the effect of unilateral removal of Na^+ from the mucosal solution. The results indicate that, except with 3-*O*-methyl glucose, when the normal Na^+ gradient is reversed, significant net sugar transport against the direction of the Na^+ gradient remains. Although the presence of Na^+ in the mucosal solution accelerates sugar influx across the brush border, it is not essential for net sugar absorption and accumulation by the small intestine.

3846 THE HYDROLYSIS AND ABSORPTION OF CONJUGATED FOLATES IN MAN. (Eng.) Jagerstad, M.; Dencker, H.; Westesson, A.-K. (Lab. Res. Clinical Hematology, Lund, Sweden). *Scand. J. Gastroenterol.* 11(3):283-287; 1976.

The distribution and activity of pteroylpolyglutamate (PPG)-hydrolase in the human gastrointestinal tract and the absorption of synthetic triglutamic folate were investigated in four patients who had been radically operated upon for cancer of the large bowel 1 yr previously. The patients were given either 1 or 2 μmol pteroyltriglutamic acid. Plasma conjugase from vena portae blood was inhibited by rapid heat denaturation. The folate forms were assayed with *Lactobacillus casei* and *Streptococcus faecalis* and were identified by thin layer chromatography. Mono- and diglutamic folate were demonstrated in the portal plasma. The PPG-hydrolyzing activity was found in the gastric juice, the intestinal juice, the pancreatic juice, and the intestinal mucosa. The highest activity, expressed as μg pteroyldiglutamate ($PteGlu_2$) and/or pteroyl monoglutamate ($PteGlu_1$) released/mg protein within 10 min, was found in the pancreatic juice. The pH optimum was a very low 3 for gastric and intestinal juice and 4.5 for pancreatic juice. The intestinal mucosa was analyzed only at pH 5.0. At pH 6, PPG-hydrolase activity of pancreatic juice was 0.07 μg PteGlu$_2$ and/or PteGlu$_1$ released/min/mg protein. In view of the volumes of these fluids produced every day, the activity at physiological pH might be enough to hydrolyze the daily intake of conjugated folates in amounts of about 500 μg.

3847 THE EFFECT OF PROTEIN DEFICIENCY ON ZINC ABSORPTION FROM THE SMALL INTESTINE AND ZINC AND COPPER CONTENTS OF RAT ORGANS. (Pol.) Kwast, M. (Panstwowy Zaklad Higieny, 00-791 Warsaw, ul. Chocimska 24, Poland). *Rocz. Panstw. Zakl. Hig.* 26(4):471-477; 1975.

3848 ABSORPTION OF MANGANESE COMPLEXES WITH AMINO ACIDS IN THE SMALL INTESTINE. (Rus.) Faitel'berg, R. O.; Ermakova, T. A. (I. I. Mechnikov Odessa State Univ., Odessa, USSR). *Fiziol. Zh. SSSR* 61(9):1415-1420; 1975.

3849 COMPARATIVE STUDY OF INTESTINAL ABSORPTION USING TRIOLEIN LABELED WITH ^{131}I OR ^{14}C. (Fre.) Dauchel, J.; Kachelhoffer, J.; Mendel, C.; Eloy, M. R.; Grenier, J. F. (Hospices Civils, F-67005 Strasbourg Cedex, France). *Acta Gastroenterol. Belg.* 38(9/10):299-313; 1975.

3850 ACTIVE TRANSPORT MECHANISMS OF THE SMALL INTESTINAL MUCOSA AND ITS FUNCTIONAL DISTURBANCES. (Ger.) Riecken, E. O. (Evangelische Diakonissenanstalt Bremen-Krankenhaus, Groepelinger Heerstrasse 406-408, D-2800 Bremen 21, W. Germany). *Z. Gastroenterol.* 14(3):407-419; 1976.

MOTILITY

3851 CORRELATION OF CONTRACTIONS AND TRANSIT IN RAT SMALL INTESTINE. (Eng.) Scott, L. D.; Summers, R. W. (Dept. Internal Medicine, Univ. Iowa, Iowa City, IA 52242). *Am. J. Physiol.* 230(1):132-137; 1976.

Experiments were designed to define the pattern of contractions, to measure net transit in the rat small intestine under fasting conditions, and to examine the effects of glucagon and cerulein on contractions, water movement, and net flow. A single strain gauge was implanted chronically in the proximal jejunum of male Sprague-Dawley rats to record contractions. Fasted pentobarbital-anesthetized animals received glucagon, cerulein, or isotonic saline control infusions i.v. while contractions were recorded. In control animals, the distribution of contractions in time showed clusters with peaks at intervals of 14.24 ± 5.6 (SD) min. Glucagon produced dose-related inhibition of contractions; the inhibition apparently being complete at 100 mg/kg/min. Cerulein, at two lower doses (0.001 and 0.01 μg/kg/min), produced a more uniform distribution of contractions in time; a higher dose (1.0 μg/kg/min) caused inhibition. In other fasted rats, an isotonically labeled bolus was given through a chronically implanted duodenal catheter, and its distribution along the small intestine was examined in animals receiving the same doses of glucagon, cerulein, and saline. Glucagon caused a dose-related delay in transit. Those doses of cerulein that produced a uniform distribution of contractions accelerated transit; the dose that inhibited contractions delayed transit. Doses of glucagon and cerulein known to affect both motility and transit did not significantly affect water movement. It is concluded that the fasted rat resembles the fasted dog in respect to the temporal distributions of jejunal contractions at a single point. Both quantitative and qualitative changes in contractions induce changes in transit.

3852 IS GASTRIN A MAJOR DETERMINANT OF BASAL LOWER ESOPHAGEAL SPHINCTER PRESSURE? A DOUBLE-BLIND CONTROLLED STUDY USING HIGH TITER GASTRIN ANTISERUM. (Eng.) Goyal, R. K.; McGuigan, J. E. (Southwestern Medical Sch., Dallas, TX 75235). *J. Clin. Invest.* 57(2):291-300; 1976.

The influence of binding of circulating gastrin with a high titer gastrin antiserum on lower esophageal sphincter pressure was studied in anesthetized oppossums. Gastrin antiserum or control antiserum was administered i.v. in successive doses of 0.02, 0.1, and 0.5 ml/kg on separate days. The lower esophageal sphincter pressures were measured for 1 hr before and for 1 hr after antiserum administration. The control serum caused no binding of opossum circulating gastrin, nor did it modify lower esophageal sphincter pressure. The administration of gastrin antiserum resulted in the binding of 85-90% of circulating gastrin, but it did not reduce sphincter pressure. A continuous infusion of 0.25 μg/kg/hr of synthetic human gastrin I caused a significant ($p<0.05$) increase in the sphincter pressure, a 30-fold increase in gastric acid output, and a 4-fold increase in immunoreactive gastrin in the blood. Prior treatment with 0.1 ml/kg of gastrin antiserum antagonized and 0.2 ml/kg of the antiserum abolished the gastrin-stimulated gastric acid secretion and the stimulating effect of gastrin on lower esophageal sphincter pressure. However, neither dose of antiserum modified basal lower esophageal sphincter pressure. It is concluded that circulating gastrin ıy not be an important determinant of basal sphinc- ɛr pressure.

353 THE EFFECT OF SECRETIN AND CHOLECYSTOKININ ON THE DUODENAL MOTILITY IN MAN.

(Eng.) snes, M. (Ulleval Hosp., Oslo 1, Norway). *Scand. . Gastroenterol.* 10(Suppl. 35):22-25; 1975.

new electrical intraluminal transducer was used to kamine the intraluminal duodenal pressure variations ıring the infusion of natural or synthetic secretin l IU/kg/hr) and 25% cholecystokinin (1 IU/kg/hr). hree transducers were coupled together, 7.5 cm from ach other, and introduced p.o. They were placed in he duodenal bulb, in the descending duodenum, and n the lower duodenal knee. Both synthetic and atural secretin inhibited the duodenal pressure ctivity in six healthy subjects, as compared to hat observed during control infusions of saline. holecystokinin had no significant effect on duodenal ressure, and rhythmic contractions were not seen uring this infusion.

354 13-NORLEUCINE MOTILIN VERSUS PENTAGASTRIN: CONTRASTING AND COMPETITIVE EFFECTS ON ASTROINTESTINAL MYOELECTRICAL ACTIVITY IN THE ONSCIOUS DOG.

(Eng.) Wingate, D. L.; Ruppin, H.; hompson, H. H.; Green, W. E. R.; Domschke, W.; unsch, E.; Demling, L.; Ritchie, H. D. (London osp. Medical Coll., London, England). *Acta Hepato- astroenterol. (Stuttg.)* 22(6):409-410; 1975.

he effect of 13-norleucine motilin (13-Nle-M, .4 μg/kg/hr) infusion on the *in vivo* electric otor activity of the stomach and small intestine as studied in three, conscious, fasted dogs. The nimals were previously prepared with eight uni- olar silver-silver chloride electrodes sutured to he serosa of the stomach, duodenum, jejunum, nd ileum. Typical aborally-propagated interdiges- ive myoelectric complexes were induced by the nfusion. The administration of pentagastrin 2.0 μg/kg/hr, i.v.) disrupted the regular inter- igestive activity and induced the typical constant attern of continuous moderate spike activity at ll recording sites. In contrast, 13-Nle-M evoked ronts of action potentials similar to the spontane- us interdigestive complex, starting in the antrum nd proximal duodenum and slowly migrating along the mall intestine to the terminal ileum in 60-80 min. imultaneous infusion of 13-Nle-M and pentagastrin aused no striking differences from electrical motor ctivity induced by pentagastrin alone. The results rovide further evidence that motilin as well as astrin may be involved in the control of gastro- ntestinal motility in dogs.

3855 THE EFFECT OF METOCLOPRAMIDE ON INTESTINAL MUSCLE RESPONSES AND THE PERISTALTIC REFLEX IN VITRO.

(Eng.) Okwuasaba, F. K.; Hamilton, J. T. (Dept. Pharmacology, Univ. Western Ontario, London, Ontario, Canada N6A 5C1). *Can. J. Physiol. Pharmacol.* 54(3):393-404; 1976.

The effect of metoclopramide (Mcp) on intestinal muscle responses and the *in vitro* peristaltic reflex was investigated in the guinea pig ileum and taenia coli, in the rabbit ileum, and in the rat duodenum. Smooth muscle preparations were mounted in an organ bath prior to drug exposure. The addition of Mcp (0.1-1.0 μM) increased ($p<0.001$) the tone and responses of the tissues to acetylcholine, carbachol, and nicotine; it had no effect on tissue responses to histamine, potassium chloride, and prostaglandin E_1. Responses to 5-hydroxytryptamine (5-HT) were decreased. Hexamethonium (50.0 μM), mepyramine (1.0 μM), and indomethacin (84.0 μM) had no significant effect on the responses to Mcp. Atropine (0.1 μM) partially and significantly inhibited the stimulatory action of Mcp by 70-75% and completely abolished the contractile responses to acetylcholine (0.01-0.60 μM). Methysergide (1.0 μM) produced a partial blockage (15-25%) of responses to Mcp, but did not abolish the response to 5-HT (0.01-0.60 μM). Tetrodotoxin (0.1 μM) produced a partial (70-75%), but significant ($p<0.001$), blockage of responses to Mcp. Similar results (60-70% inhibition) were obtained with morphine (50.0 μM). Metoclopramide (1.0 μM) lowered the threshold of the peristaltic reflex to a subthreshold intraluminal pressure (2.5 cm H_2O), facilitated the peristaltic response to threshold pressures (3-4 cm H_2O), and restored the reflex in fatigued preparations, but not in those depressed by cooling to 24 C. During blockage of peristalsis by atropine, hexamethonium, or methysergide (applied serosally), 5-HT (0.25 μM), but not Mcp (1.0 μM), effectively restored the peristaltic reflex. Neither antagonized the inhibition by morphine or procaine acting serosally. These results do not support the hypothesis that the stimulatory action of Mcp is entirely dependent on either peripheral sensitization of muscarinic receptors or an action on tryptaminergic mechanisms, and are consistent with the authors' previously published conclusion that an additional component may be a blockade of some intrinsic inhibitory substance normally restraining intestinal motility or tone.

3856 THE SIGNIFICANCE OF DISTENTION FOR THE EFFECT OF GLUCAGON ON THE FUNDIC AND ANTRAL MOTILITY IN ISOLATED GUINEA-PIG STOMACH.

(Eng.) Gerner, T.; Haffner, J. F. W. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(Suppl. 35): 51-53; 1975.

Experiments were conducted to determine the *in vitro* effect of glucagon on antral and fundal motility of the guinea pig stomach and to determine whether the effect of glucagon is related to the degree of distention of the antrum and fundus. The pressure in the isolated antrum and fundus was recorded with fluid-filled balloons connected to transducers; the balloon volumes were increased stepwise, until the pressure was approximately 15 cm H_2O. Glucagon (10 μg/ml) were added at each step of distension in eight preparations, and the motility recordings were compared with those from nine control preparations not exposed to glucagon. Glucagon inhibited gastric motility in both parts of the stomach. The inhibitory effect on antral motility was obtained only

LIBRARY U.

when the pouches were maximally distended. This inhibitory effect was not related to the degree of distention in the fundus, but the reduction in basal pressure was markedly enhanced by distention. It is concluded that glucagon has a direct inhibitory effect on gastric motility *in vitro;* this effect is most marked in the fundus and most easily elicited in distended preparations.

3857 ACTION OF COHERIN ON THE BASIC ELECTRICAL RHYTHM AND PROPAGATION IN THE ISOLATED PERFUSED CANINE JEJUNUM. (Eng.) Mendel, C.; Jaeck, D.; Grenier, J. F.; Hiatt, R. B.; Goodman, I.; Sandler, B. (Univ. Medical Sch., INSERM, Avenue Moliere, Strasbourg, Hautepierre, France). *J. Surg. Res.* 19(6):403-409; 1975.

The action of coherin on the basic electrical rhythm (BER) and propagation in the isolated perfused canine jejunum was investigated *in vitro* in six mongrel dogs. Six silver-silver chloride punctate wire electrodes were inserted into the longitudinal muscle of the jejunum. Simultaneous electroenterogram (ENG) recordings were made from the electrodes. Pre- and postinjection (250 ng coherin) ENG recordings were made. There was an average gain in coherence by a factor of 3 following injection of coherin ($p<0.0005$). A post-coherin ENG using another preparation recorded 1 hr after the coherin injection showed that the coherence index was 56%, up from 20% in the pre-coherin base period. The average BER frequency was 13.8 cycles/min. The highest degree of coherence was a 73% coherence index obtained 41 min after injection of another preparation. Coherin, a peptide of the neurohypophysis, acts to regulate the propagative characteristics of the jejunal BER without intervention of extrinsic neutral or humoral factors.

SECRETION AND METABOLISM

3864 PROLONGED ETHANOL CONSUMPTION INCREASES TESTOSTERONE METABOLISM IN THE LIVER. (Eng.) Rubin, E.; Lieber, C. S.; Altman, K.; Gordon, G. G.; Southern, A. L. (Mt. Sinai Sch. Medicine, New York, NY 10029). *Science* 191(4227): 563-564; 1976.

The effect of ethanol on hepatic testosterone reductase activity was studied in 16 male Sprague-Dawley rats, in three nonalcoholic men, and in two chronic alcoholics. Each of the rats was paired with anothe animal, one being fed a nutritionally adequate diet containing 36% carbohydrate, and the other being fed a similar diet in which ethanol was isocalorically substituted for carbohydrate. The animals were killed after 24 days. The mean activity of testosterone reductase in the microsomal fraction was more than doubled, while that in the soluble fraction was essentially unchanged. All five human subjects were given a diet containing excess protein, vitamins, minerals, and approximately 3 g/kg/day ethanol for 4 weeks. The reductase activity, which was measured in whole homogenates of aspiration liver biopsy specimens before and after ethanol administration, was augmented between two- and fivefold after ethanol administration. An increase in the activity of testosterone reductase may enhance the removal of testosterone and other Δ^4-3-ketosteroids in the liver, which, in turn, may play a role in the reduced androgenic activity found in chronic alcoholics.

3865 GASTRIC INHIBITORY POLYPEPTIDE (GIP) STIMULATED BY FAT INGESTION IN MAN. (Eng.) Falko, J. M.; Crockett, S. E.; Cataland, S.; Mazzaferri, E. L. (Dept. Medicine, Ohio State Univ., Columbus, OH 43210). *J. Clin. Endocrinol. Metab.* 41(2):260-265; 1975.

The immunoreactive gastric inhibitory polypeptide (GIP), insulin (IRI), and nonesterified fatty acid (NEFA) responses were measured in 10 normal subjects who ingested emulsified corn oil (67 g Lipomul). Serum GIP levels rose after the ingestion of corn oil in all subjects, increasing from a mean fasting level of 272 pg/ml to 856 ± 272 pg/ml ($p<0.05$) by 30 min. The peak mean serum GIP concentration of 1,345 ± 291 pg/ml occurred at 60 min; and mean serum GIP levels at 180 min remained significantly elevated over fasting values. Serum IRI, glucose, and NEFA concentrations did not change during the 180 min of study. No changes in serum GIP concentrations occurred when, for control purposes, six volunteers ingested 100 ml of water on another day. It is concluded that fat is a potent stimulus for the release of GIP in normal individuals, and that endogenously released GIP is not insulinotropic under the conditions of this study.

SECRETION AND METABOLISM

Stomach

3869 REVERSIBILITY OF EFFECTS OF VERY HYPOTONIC FLUIDS ON IN VITRO FROG GASTRIC MUCOSA: A FUNCTIONAL AND MORPHOLOGICAL STUDY. (Eng.) Helander, H. F.; Sanders, S. S.; Shanbour, L. L.; Rehm, W. S. (Medical Center, Univ. Alabama Birmingham, Birmingham, AL). *Acta Physiol. Scand.* 95(4):353-363; 1975.

Functional and morphological properties of the *in vitro* frog gastric mucosa were studied during and after exposure to very hypotonic (≈25 mOsm) solutions. Within 20 min, the acid secretory rate decreased to zero, but it returned to normal levels after isotonic fluids were restored. The potential difference (PD) dropped within the first minutes after the exposure to hypotonic solutions, and became inverted. Following the return of isotonic conditions, the PD increased to levels higher than in the controls. The electrical resistance increased about 10-fold during the hypotonic period, but decreased to near normal values when isotonic conditions were restored. By light and electron microscopy, the cells of the hypotonic mucosa appeared greatly swollen, and the alterations were assessed by morphometric methods. The gland lumina were almost obliterated, and the lamina propria was reduced to about 60% of its former volume. After the return to isotonic conditions, normal morphology was restored. The great increase in resistance during the hypotonic period may have been caused by the occlusion of the gland lumina. Quantitative analyses of the Na, K, and Cl tissue concentrations by flame photometry and by a chloridimetry technique indicated a large loss of these ions during the hypotonic state. It is suggested that the epithelial cells in the hypotonic mucosae avoid bursting by rapidly letting large numbers of ions exit, which results in a cellular osmolarity close to that of the bathing fluids.

3870 METABOLISM OF HISTAMINE IN SECRETING INTACT AND ISOLATED CANINE STOMACH. (Eng.) Code, C. F.; Green, W. E. R.; Kennedy, J. C.; Ritchie, H. D.; Schlegel, J. F. (CURE, Building 115, Veterans Admin. Wadsworth Hosp., Los Angeles, CA 90073). *Am. J. Physiol.* 230(1):219-227; 1976.

Total ^{14}C activity in juice secreted by the gastric pouches of six dogs and seven isolated canine stomachs was determined in response to i.v. and intra-arterial (i.a.) infusions of histamine and [^{14}C]histamine. Histamine (1-3.5 µmol/hr, i.v.) was administered to intact dogs, producing secretory outputs from the pouches ranging from 25-65% of maximum. In the isolated stomachs, histamine (4 µmol/hr, including 250 µCi of [^{14}C]histamine) was administered into the arterial line. The proportions of ^{14}C attributable to histamine, N^{α}-methylhistamine (N^{α}MeH), N^{α}, N^{α}-dimethylhistamine ($N^{\alpha}N^{\alpha}$Me$_2$H), N-telle-methylhistamine (N^{τ}MeH), imidazole acetic acid (ImAA), N-methylimidazole acetic acid (N^{τ}MeImAA), acetylhistamine (AcH), and histaminol (HOH) were defined using thin layer chromatography. Similar estimates were made at the end of infusions on blood, gastric mucosa, and gastric muscle. Histamine and its primary methylated products accounted for 29% of the total ^{14}C activity in the juice from intact dogs, while histamine and its primary methylated products accounted for 70% of the total activity in the gastric juice from isolated perfused stomachs. Methylation was the major, or sole, route of metabolism of histamine in the gastric mucosa, and the major product was inactive N^{τ}MeH. Small quantities of the active N^{α}Me derivatives, particularly $N^{\alpha}N^{\alpha}$Me$_2$H, were identified in both the juice and mucosa. Little or no ImAA, N^{τ}MeImAA, AcH, or HOH was present in juice from isolated stomachs, while these products did occur in the juice from intact dogs, demonstrating that they are extragastric metabolites of histamine. It is concluded that methylation is the major, and likely the sole, route of histamine metabolism in the gastric mucosa of the dog.

3871 ETHANOL, INDOMETHACIN AND GASTRIC ACID SECRETION IN THE RAT. (Eng.) Karppanen, H.; Puurunen, J. (Dept. Pharmacology, Univ. Oulu, SF-90 220 Oulu 22, Finland). *Eur. J. Pharmacol.* 35(1):221-223; 1976.

Experiments were performed to determine whether the ethanol-induced decrease of gastric acid secretion observed in the rat is attributable to an increased production of prostaglandins. The secretion of gastric acid was determined by a perfusion method in anesthetized, male Sprague-Dawley rats. After the rate of the acid secretion was stabilized (in approximately 1 hr), 10% ethanol (4 ml/5 min for 60 min, i.v.) was given to 15 animals. A total cessation of gastric acid output was seen within 30-60 min. In 11 animals pretreated with indomethacin (30 mg/kg, i.v.) 90 and 30 min before administration of ethanol, the inhibition ranged from 0-83% (mean 51%). The results suggest that the inhibitory effect of local ethanol on gastric acid secretion in the rat may be mediated, at least partly, by increased synthesis of prostaglandins.

3872 EFFECTS OF ISOPROPYLNORADRENALINE ON TACHYPHYLAXIS OF GASTRIN STIMULATED GASTRIC ACID SECRETION AND MUCOSAL BLOOD FLOW IN THE ANAESTHETIZED CAT. (Eng.) Reed, J. D.; Smy, J. R. (Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne, NE1 7RU, England). *J. Physiol. (Lond.)* 254(1):153-168; 1976.

The effect of isopropylnoradrenaline (IPNA)-induced gastric hyperemia on gastric acid secretion in the cat was investigated to determine the role of mucosal blood flow in the secretory response to gastrin. Gastrin was given i.v. as large doses [20-30 µg pentapeptide/15 min and 25 or 30 mg/15 min of a crude aqueous extract of the pyloric gland area (P.G.A.) which contains gastrin], or in small doses (1 µg pentapeptide/15 min and 1.0 or 0.25 mg P.G.A./15 min). The IPNA was infused arterially via the retrograde hepatic artery cannula or i.v. in doses that had no effect on systemic blood pressure. The pattern of response to large doses of pentapeptide (20-30 µg/15 min) was a rapid increase in acid output and mucosal blood flow (MBF), which followed the onset of stimulation and usually achieved maxima within an hour, progressively declining thereafter, despite continued stimulation. There was a significant negative correlation of acid secretion and MBF with time ($p<0.001$ for both). The pattern of acid and MBF responses to low doses of gastrin was similar to that with larger doses of gastrin, but the mean acid peak and MBF peak were lower. Infusion of IPNA produced increases in blood flow unrelated to time following the peak response to large doses of gastrin, while increases in acid appeared to be a partial removal of the acid tachyphylaxis. During stimulation by small doses of gastrin, IPNA increased both MBF and acid secretion above the peak responses to gastrin alone. Increases in gastrin-stimulated acid and MBF were also produced by expansion of the blood volume by a 7% dextran, 0.9% saline infusion. It is concluded that tachyphylaxis of gastric acid secretion to gastrin may be a function of the primary tachyphylaxis of MBF.

3873 THE INFLUENCE OF PROPRANOLOL ON SERUM GASTRIN CONCENTRATION AND HYDROCHLORIC ACID SECRETION IN RESPONSE TO HYPOGLYCEMIA IN NORMAL SUBJECTS. (Eng.) Kaess, H.; Kuntzen, O.; Teckentrupp, U.; Dorner, M. (Dept. Internal Medicine, Univ. Heidelberg, Heidelberg, W. Germany). *Digestion* 13(4):193-200; 1975.

The effect of propranolol (50 µg/kg, i.v. for 3 min) on serum gastrin concentration and HCl secretion during insulin hypoglycemia (0.2 U/kg insulin, i.v., 15 min after propranolol or saline) was inves-

LIBRARY U.

gated in 10 normal subjects. Blood samples were
ken at intervals up to 2 hr following insulin
ministration. Serum gastrin concentrations in-
eased from 139 to 179 pg/ml ($p<0.05$) 45 min after
sulin and declined slowly to 153 pg/ml. Propran-
ol decreased the fasting gastrin concentration
om 146 to 133 pg/ml ($p<0.05$) at 15 min, and the
vel was 136 pg/ml ($p<0.05$) at 30 min. The inte-
ated gastrin response to insulin was 1.0 ± 0.3 ng
the first hr and 2.2 ± 0.05 ng during the 2-hr
riod. Propranolol reduced the rise of gastrinemia
0.040 ± 0.20 ng/hr and 0.090 ± 0.30 ng/2 hr,
sp., ($p<0.01$). The secretion of HCl rose following
sulin administration from a base level of 0.75-
01 mEq/15 min to 5.7 mEq/15 min after 75 min, and
en decreased to 3.5 mEq/15 min after 2 hr.
opranolol increased the HCl secretion to insulin
poglycemia to a peak of 3.0 mEq/15 min at 75 min;
e level then fell to 2.5 mEq/15 min. The HCl
cretion was significantly lower between 45 and
5 min after insulin than in the control series
<0.05). The peak acid output was 12.6 ± 1.2 mEq/30
n compared to 7.5 ± 1.0 mEq/30 min ($p<0.02$) in the
opranolol experiments, and 30.3 ± 2.2 mEq compared
18.3 ± 2.3 mEq for tne 2-hr period ($p<0.01$).
e results support the hypothesis that there is a
-adrenergic component for the release of gastrin
d the secretion of HCl.

874 PROTEIN SYNTHESIS IN HUMAN GASTRIC MUCOSA:
EFFECTS OF PENTAGASTRIN, SECRETIN, AND 13-
le-MOTILIN. (Eng.) Mitznegg, P.; Domschke, W.;
omschke, S.; Belohlavek, D.; Sprugel, W.; Strunz, U.;
unsch, E.; Jaeger, E.; Demling, L. (Dept. Pharma-
ology, Univ. Erlangen-Nurnberg, Erlangen, W. Ger-
any). *Acta Hepatogastroenterol. (Stuttg.)* 22(5):
33-335; 1975.

he effects of pentagastrin, secretin, and motilin
n gastric mucosal protein synthesis were studied in
5 fasted volunteers. In a total of 29 observations,
he mean *in vitro* incorporation of ^{14}C-leucine into
he proteins of fundic gastric mucosa was 41.2 ±
.7 x 10^3 counts per min/mg protein. This figure
ncreased significantly in samples taken 1 and 4 hr
fter the subjects were given pentagastrin (6 μg/kg,
.c.) by 18.9% and 21.8%, resp. Secretin (2 clinical
/kg, i.v.) caused a 10.5% inhibition of leucine in-
orporation within a period of 1 hr, but this was
ot statistically significant. After continuous
.v. infusion of 13-norleucine-motilin (13-nle-
otilin, 0.4 μg/kg at 0.5 ml/min for 1 hr), the
ncorporation rate was reduced by 17.5%. Penta-
astrin did not change the rate of protein synthesis
n the duodenal mucosa. The data support the hypo-
hesis that in man, as well as in animals, penta-
astrin and gastrin may both have a trophic influ-
nce on the gastric mucosa.

875 GASTRIC SECRETION DURING ANAESTHESIA AND
ITS INHIBITION BY METIAMIDE AND OTHER
RUGS. (Eng.) Schachter, M.; Karpinski, E.;
aines, V. (Dept. Physiology, Univ. Alberta, Edmon-
ton T6G 2E1, Alberta, Canada). *Experientia* 31(8):
64-965; 1975.

The effects of metiamide, atropine, and hexamethonium on gastric acid secretion produced by chloralose-urethane anesthesia and by histamine were investigated in dogs. Metiamide (3.0 mg/kg, i.v.), when administered before or shortly after histamine (15-25 μg/kg, s.c.), either abolished or reduced to near zero the resulting gastric secretion in three experiments on two dogs. In three experiments on two dogs in which the animals were "spontaneously" secreting despite an empty stomach, the administration of metiamide also arrested the secretion, which was presumably of vagal origin since it was also abolished by atropine (75 μg/kg, i.v.). The same dosage of metiamide administered either just before or during anesthesia with a chloralose-urethane mixture (25 mg chloralose, 250 mg urethane/ml; 2.0 ml/kg, i.v.) produced a gastric secretion inhibition similar to that observed with the histamine-induced secretion in seven experiments on five dogs. The inhibitory effect was more effective if metiamide was given just prior to the induction of anesthesia. The administration of atropine (75 or 100 μg/kg, i.v.) or hexamethonium (3 mg/kg, i.v.) during anesthesia arrested acid secretion for observation periods of up to 60 min. It is clear that histamine H_2-receptor antagonists, perhaps in combination with anticholinergic agents, suppress gastric secretion of physiological or pathological origin.

3876 CHANGED CHOLINERGIC RECEPTOR CHARACTERISTICS AFTER VAGOTOMY IN GASTRIC FISTULA DOGS. (Eng.) Hirschowitz, B. I.; Gibson, R.; Wright, L.; Hutchison, G. (Univ. Alabama Medical Center, Birmingham, AL 35294). *Am. J. Physiol.* 230(1):105-109; 1976.

The kinetics of atropine antagonism to Urecholine- and pentagastrin-stimulated acid and pepsin secretion were defined in intact dogs with gastric fistulae and in dogs after fundic vagotomy. Although pentagastrin (0.1-10 μg/kg hr, i.v. in 45-min incremental step doses) was a much less effective stimulus after vagotomy, atropine (0.2-10 μg/kg hr) had very similar effects on the pentagastrin response before and after vagotomy. Stimulation of both acid and pepsin by Urecholine (20-320 μg/kg hr) remained unchanged by vagotomy but was uncompetitively inhibited by atropine in the intact dog, suggesting irreversible binding of atropine to gastric cholinergic receptors. However, after vagotomy, atropine inhibited Urecholine competitively, suggesting that atropine was now bound reversibly to cholinergic receptors. These changes are analogous to those occurring in muscle after denervation and suggest the growth of new cholinergic receptors with changed characteristics after denervation of the stomach.

3877 EFFECT OF BULBAR ACIDIFICATION ON BASAL SECRETION OF ACID AND GASTRIN IN DOG. (Eng.) Nilsson, G. (Dept. Pharmacology, Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 95(4):477-481; 1975.

Experiments were conducted to determine whether acid perfusion of bulbar pouches induces acid secretion in Pavlov pouch dogs and whether acid perfusion influences plasma gastrin levels in these dogs. Five dogs were provided with mucosal septal pouches of the stomach and of the duodenal bulb. In some dogs, a gastric drainage cannula was inserted into the most dependent portion of the stomach. In dogs, which were found to secrete acid spontaneously during a control period at the start of each experiment, the bulbar pouches were perfused with 0.1 M HCl for 5-120 min. Bulbar acidification rapidly and profoundly reduced the basal acid output. In dogs, which did not secrete acid spontaneously during the control period, bulbar pouches were perfused with 0.1 M HCl for 1 hr. Bulbar acidification did not significantly influence the plasma gastrin concentration, and no acid was secreted from the Pavlov pouches following such acidification. The results support the hypothesis that reduction of the intrabulbar pH may contribute to the reduction of acid secretion during interdigestive periods. The physiological significance of mechanisms in the upper intestine that induce acid secretion following a reduction of the intraluminal pH is questioned.

LIBRARY U. OF

3878 ACTION OF SOMATOSTATIN AND METIAMIDE ON GASTRIC ACID SECRETION FROM ISOLATED BULLFROG GASTRIC MUCOSA. (Eng.) Warrick, M. W.; Lin, T.-M. (Lilly Res. Labs., Indianapolis, IN 46206). *Res. Commun. Chem. Pathol. Pharmacol.* 13(1):149-152; 1976.

The actions of somatostatin and metiamide on histamine- or pentagastrin-stimulated acid secretion were studied in the isolated bullfrog gastric mucosa. The doses of somatostatin and metiamide required for 50% inhibition of acid secretion induced by 10^{-5} M pentagastrin (control level $\geq$ 8 µEq/hr) were 7.36 x 10^{-6} M and 8.7 x 10^{-6} M, resp., and those for 20% inhibition of acid secretion were 3 x 10^{-8} M and 9.5 x 10^{-7} M, resp. The doses of somatostatin and metiamide required for 50% inhibition of acid secretion induced by 10^{-5} M histamine were 7.7 x 10^{-6} M and 6.3 x 10^{-5} M, resp., and for 20% inhibition, 6 x 10^{-8} M and 9.1 x 10^{-6} M, resp. Somostatin at 4.7 x 10^{-8} M suppressed spontaneous acid secretion by 50%. The slopes of the dose-response curves relating somatostatin and percent of inhibition, and those between metiamide and percent of acid inhibition, were different, suggesting that the mechanisms by which somatostatin and metiamide inhibit acid secretion are not the same.

Pancreas

889 LONG-TERM ORGAN CULTURE OF EMBRYONIC RAT PANCREAS IN A CHEMICALLY DEFINED MEDIUM.

Eng.) Parsa, I.; Marsh, W. H. (State Univ. New ork, Downstate Medical Center, 450 Clarkson Ave., rooklyn, NY 11203). *Am. J. Pathol.* 82(1):119-128; 976.

he morphologic, ultrastructural, and enzymatic evelopment of embryonic rat pancreas during long-erm organ culture was investigated. Embryonic at pancreas anlagen were grown in a chemically-efined medium, subdivided biweekly, and recultured or a total time of 10 weeks. The total mass incre-ent during the 10 weeks was in excess of 1,000-fold. amples were removed for light and electron micro-copic examination and for periodic measurement of nzymatic activity. Morphogenesis and cytodifferen-iation occurred. Peripheral outgrowth of epithelial uds was followed by the formation of interconnecting ubular structures and on days 4-7 of culture, by the ppearance of distinctive acinar cells with zymogen ranules. Mitotic figures became conspicuous at the eriphery of explants within a day after each sub-ivision, resulting in the formation of new tubular tructures and acini. In general, the central area f the explants presented more mature acini with ymogen granules than the periphery. While exogenous nsulin (8.0 mg/l of medium) and glucagon (4.0 mg/l f medium) were not requirements for short-term ulture (9 days), their addition was necessary for ong-term maintenance of culture. Hydrocortisone 4.0 mg/l of culture) improved the viability of cells uring prolonged cultures. The enzymatic activities f amylase, lipase, and chymotrypsin developed maxi-ally during the first week of culture, reached a lateau level by the second week, and remained at a elatively constant level throughout the 10-week cul-ure period. The results show that long-term organ ulture of embryonic rat pancreas beyond a 10-week eriod was successfully achieved.

890 STUDIES ON INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE RAT EXOCRINE ANCREAS. II. INHIBITION BY ANTIMICROTUBULAR GENTS.

(Eng.) Seybold, J.; Bieger, W.; Kern, . F. (Dept. Anatomy, Univ. Heidelberg, D-6900 eidelberg, Im Neuenheimer Feld 307, W. Germany). *irchows Arch.* [*Pathol. Anat.*] 368(4):309-327; 975.

he possible role of microtubules and microfilaments n the secretory process of the rat exocrine pan-reas was analysed *in vitro* using isolated pancrea-ic lobules. The lobules were incubated with col-hicine, vinblastine, hexylene glycol, and cytochala-in B, and their effect on the three major steps in he secretory cycle (protein synthesis, intracellular ransport of newly synthesized proteins, and dis-harge of zymogen granules) was compared with ellular respiration. Colchicine, 10^{-2} M, inhibited rotein synthesis, while vinblastine caused 20% nhibition at 10^{-6} and 10^{-5} M and 55% inhibition t 10^{-4} M. A similar inhibition was observed with 1.5% hexylene glycol, while cytochalasine B at 1.5 and 10 μg/ml had no effect on protein synthesis. Colchicine and vinblastine had major effects on intracellular transport, both in secretion studies and cell fractionation experiments. Colchicine (10^{-3}-10^{-5} M) inhibited the discharge of newly synthesized proteins by 50%, while vinblastine showed a dose-response relation of 40% inhibition at 10^{-6} M to 90% at 10^{-4} M. Discharge of amylase was uniformly reduced by 30% by both colchicine and vinblastine in the entire dose range. In cell fractionation studies, both colchicine and vinblastine inhibited the disappearance of protein radioactivity from microsomes and its appearance in zymogen granules; similarly, the peak radioactivity in smooth microsomes (Golgi) appeared delayed. No differential effect on the secretory process was observed with 1.5% hexylene glycol or cytochalasin B (1.5 and 10 μg/ml). A fine structural analysis of microtubules and microfilaments in the exocrine pancreatic cell revealed their distribution in all parts of the cytoplasm and in relation to all cell organelles. Both systems (microtubules and microfilaments) seemed to be connected, at least in certain areas of the cytoplasm and at the plasma membrane. The reduction of transport efficiency by microtubule inhibitors resulted in a deposition of secretory material in the cisternal space of the rough endoplasmatic reticulum, which leads to the formation of paracrystals. Colchicine (10^{-3} M) caused an enlargement of condensing vacuoles in the Golgi complex. It is concluded that antimicrotubular agents have both specific and nonspecific cytotoxic actions.

3891 COMPARISON OF VASOACTIVE INTESTINAL PEPTIDE AND SECRETIN IN STIMULATION OF PANCREATIC SECRETION.

(Eng.) Konturek, S. J.; Pucher, A.; Radecki, T. (Inst. Physiology Medical Academy, Cracow, Poland). *J. Physiol. (Lond.)* 255(2):497-509; 1976.

Pancreatic volume flow and bicarbonate and protein secretion were measured in response to i.v. infusion of vasoactive intestinal peptide (VIP) and secretin or duodenal perfusion of sodium oleate and HCl solution in cats and dogs with chronic pancreatic fistula. Graded doses of VIP or secretin in cats evoked graded increases in pancreatic secretion that reached the highest level at doses of 16 μg/kg/hr and 4 U/kg/hr, resp. The addition of cerulein (0.2 μg/kg/hr) to VIP significantly ($p<0.01$) increased the dose-response curve for bicarbonate above that of VIP alone. The secretory response to secretin combined with cerulein (0.2 μg/kg/hr) or with VIP (4 μg/kg/hr) was significantly higher than to secretin alone, particularly at lower dose levels. Sodium oleate and HCl solution instilled into the duodenum of cats at graded doses produced similar pancreatic dose-response curves for volume flow and bicarbonate output, which reached 80 and 70%, resp., of the maximal observed response to exogenous VIP or secretin. Duodenal perfusion of oleate in dogs also stimulated pancreatic secretion in a dose-related manner. The highest maximal bicarbonate response to oleate was reached at 8.0 mM oleate, and it was 38% of that reached with exogenous secretin. The highest observed protein response to cerulein in dogs was reached at a dose of 0.5 μg/kg/hr and amounted to about 800 mg protein/30 min. Oleate and HCl were less effective stimulants of protein secretion, reaching 87 and 63%, resp., of that induced by cerulein. The results of the combined study on cats and dogs provide strong support for the concept that oleate releases VIP and that the difference in pancreatic secretion is due to the species-dependent pancreatic responsiveness to this peptide.

3892 ABSENCE OF EFFECTS OF DIBUTYRYL CYCLIC GUANOSINE 3',5'-MONOPHOSPHATE ON RELEASE OF α-AMYLASE, ^{45}Ca EFFLUX, AND PROTEIN SYNTHESIS IN RAT PANCREAS IN VITRO. (Eng.) Heisler, S.; Grondin, G. (Centre Hospitalier Universitaire, Universite Sherbrooke, Sherbrooke J1H 5NE, Quebec, Canada). *Experientia* 31(8):936-938; 1975.

The effect of dibutyryl cyclic guanosine-3'5'-monophosphate (dibutyryl cyclic GMP) on α-amylase release, ^{45}Ca efflux, and protein synthesis was studied in pancreas fragments from female Sprague-Dawley rats. Dibutyryl cyclic GMP (10^{-7}-10^{-3} M) did not alter basal α-amylase release (5.87% release in controls and 6.85% release with dibutyryl cyclic GMP) during a 30-min incubation period. Dibutyryl cyclic GMP did not influence carbachol (10^{-5} M)-stimulated enzyme release (12.48% release in controls and 13.83% release with dibutyryl cyclic GMP). At 10^{-5} M, dibutyryl cyclic GMP moderately increased the efflux rate of ^{45}Ca, although the increase was not statistically significant. Carbachol (10^{-5} M) increased the rate of ^{45}Ca efflux in comparison to untreated tissues, but depressed the rate of incorporation of ^{3}H-leucine into newly synthesized protein (from 879 dpm/mg/20 min in controls to 480 dpm/mg/20 min with carbachol). The latter effect was not duplicated by dibutyryl cyclic GMP (10^{-5} M) nor did the nucleotide alter the effect of carbachol. The results suggest that dibutyryl cyclic GMP does not affect the release of α-amylase, ^{45}Ca efflux, or protein synthesis in the rat pancreas *in vitro*. The results emphasize that exogenous dibutyryl cyclic GMP may be an agent of limited usefulness in confirming the hormonal actions of parasympathomimetic substances.

3893 CHANGES IN AMINO ACID TRANSPORT IN THE RAT PANCREAS IN RESPONSE TO FASTING AND FEEDING. (Eng.) Cheneval, J. P.; Johnstone, R. M. (Departement Sciences Biologiques, Universite du Quebec a Montreal, Montreal, Quebec, Canada). *Biochim. Biophys. Acta* 433(3):630-637; 1976.

The effect of feeding and fasting on changes in the transport of amino acid (*in vitro*) were investigated in the pancreas of young and adult Sprague-Dawley rats. A fast of 24 hr (young animals) or 48 hr (adult animals) reduced the uptake rate of aminoisobutyrate in the isolated rat pancreas *in vitro* following a 90-min incubation period. In contrast, refeeding of animals after a fast showed an increase in amino acid transport in young as well as adult animals. The effects of refeeding after a fast were mimicked, to a significant extent, by injection of mixtures of pancreozymin (5 Crick U/100 g body weight) and carbamylcholine (10^{-5} μmol). Addition of these agents *in vitro* had no effect. The incorporation of amino acids into the total proteins of the rat pancreas followed the pattern of amino acid uptake. Even at high external glycine (5 mM) levels, incorporation increased, although the glycine level in the cell was in excess of 25 mM. Reduction of glycine uptake by ouabain by 75% resulted in a substantial (44%) diminution of amino acid incorporation into proteins. The data suggest that inhibition of amino acid incorporation under the various metabolic conditions examined is due largely to a decreased availability of amino acids.

3894 PROTEIN SYNTHESIS AND SECRETION IN THE COBALT CHLORIDE DAMAGED EXOCRINE PANCREAS OF GUINEA PIGS. (Eng.) Jonas, L.; Putzke, H.-P.; Bienengraber, A. (Institut fur Allgemeine und Spezielle Pathologie, Universitat Rostock, DDR-25 Rostock, Strempelstrasse 14, E. Germany). *Exp. Pathol. (Jena)* 11(1/2):73-82; 1975.

A combined electron microscopic-autoradiographical investigation was used to examine disturbances in the mechanism of pancreatic acinar cell secretion produced by cobalt chloride ($CoCl_2$). Thirty-five male guinea pigs were given a single s.c. injection (20 mg $CoCl_2$/kg body weight) or, with a 24-hr spacing, a second or third s.c. injection (20 mg $CoCl_2$/kg body weight). Four hr before sacrifice, a single dose of ^{3}H-leucine (2 mCi, i.p.) was administered to each animal. Following administration of $CoCl_2$, the secretion of the exocrine pancreas decreased. During the first 12 hr, zymogen granules were extruded, but newly formed zymogenic material was pathologically stored in the Golgi complex. Under these conditions, regular enzyme granules were seldom formed, and the apical cell pole appeared nearly free of typical enzyme granules. By the third day, the Golgi apparatus had almost disappeared. Radioactive labeling showed that newly synthesized proteins were stored in the cisternae of the endoplasmic reticulum as granules. The Golgi apparatus seemed to be the center of the $CoCl_2$ attack. During the first phase, its transport and concentration functions were disturbed, with enzymes being stored in the cavity system. In the second phase, sufficient synthesis of new membrane was halted. There was damage to the mitochondria. The cobalt caused a marked inhibition of the activity of a series of enzymes, especially of succinic dehydrogenase, which was indicative of an energy shortage. This was compensated, in part, by the production of giant mitochondria after two or three days. It was not clear whether the damage to the Golgi apparatus was a primary or a secondary disturbance caused by an impairment of the mitochondria. The authors conclude that a combined electron microscopic-autoradiographic investigation makes qualitative and quantitative statements about disturbances in the mechanism of

LIBRARY U.

pancreatic acinar cell secretion under the influence of $CoCl_2$ possible, especially as far as the Golgi apparatus is concerned.

3895 ROLE OF CALCIUM IN EXOCRINE PANCREATIC SECRETION. II. COMPARISON OF THE EFFECTS OF CARBACHOL AND THE IONOPHORE A-23187 ON ENZYME SECRETION AND CALCIUM MOVEMENTS IN RABBIT PANCREAS. (Eng.) Schreurs, V. V. A. M.; Swarts, H. G. P.; De Pont, J. J. H. H. M.; Bonting, S. L. (Dept. Biochemistry, Univ. Nijmegen, Nijmegen, Netherlands). *Biochim. Biophys. Acta* 419(2):320-330; 1976.

The role of calcium in exocrine pancreatic secretion was studied by comparing the effects of carbachol and ionophore (A-23187) on calcium movement and amylase secretion in the isolated pancreas and pancreas fragments of New Zealand white rabbits. The fragments were preloaded with $^{45}Ca^{++}$ for 2 hr and then washed. Following a control period, there were either five 15-min efflux periods or 24 5-min experimental periods. Amylase activity and radioactivity were determined using the internal standard method. Protein and calcium concentrations were also determined. When 10^{-5} M carbachol was added to the efflux medium, there was an immediate increase in the efflux of amylase and Ca^{++}. The Ca^{++} efflux returned to normal after 30 min, but the increase in amylase efflux continued for the remainder of the experiment. The addition of A-23187 (10^{-6} M) resulted in only a small increase in amylase efflux and had only a slight effect on Ca^{++} efflux in the Ca^{++}-free medium. When, 30 min later, the Ca^{++}-free medium was replaced by a Krebs-Ringer bicarbonate medium (with or without Mg^{++}), a significant increase in amylase efflux was found, while the $^{45}Ca^{++}$ efflux rate decreased. The action of A-23187 is Ca^{++}-dependent, whereas this dependency is much less for carbachol. Since the cytoplasmic Ca^{++} concentration is very low, the effect of carbachol cannot be explained by increased Ca^{++} permeability of the serosal membrane. Carbachol released Ca^{++} from intracellular stores not attached by A-23187. It is suggested that increased cytoplasmic Ca^{++} is essential in the physiological stimulus-secretion coupling and that the Ca^{++} originates intracellularly, indicating that Ca^{++} acts as a third messenger in the pancreatic stimulus-secretion coupling.

3896 CALCIUM-ACTIVATED ATPase ACTIVITY IN A PLASMA MEMBRANE RICH PREPARATION OF RAT PANCREAS. (Eng.) Forget, G.; Heisler, S. (Dept. Physiology, Univ. Sherbrooke, Sherbrooke, Quebec, Canada). *Clin. Exp. Pharmacol. Physiol.* 3(1):67-72; 1976.

Calcium-stimulated ATPase activity was studied in a plasma-membrane-rich fraction of Sprague-Dawley rat pancreas homogenate to determine whether it is responsive to pancreozymin (PZ) and/or carbachol. The ATP hydrolytic activity of the plasma membrane was assessed in the presence of a varying concentration of Ca (0.125-4 mM) or Mg (0.25-4 mM). Peak hydrolytic activity was observed with a concentration of 1-2 mM Ca or 2 mM Mg. The addition of 2 mM Mg to a buffer containing 1 mM Ca increased the hydrolytic activity only slightly (13%). Monovalent cations such as Na^+ (10-100 mM) or K^+ (0.5-10 mM) did not affect the ATPase activated by 1 mM Ca. The addition of ouabain (2 mM) or 2,4-dinitrophenol (0.1-0.2 mM) to the incubation had no effect on the enzyme activity stimulated by Ca (1 mM). Pancreozymin (0.01-2 Crick U/ml) inhibited the enzyme activated in the presence of 1 mM Ca from 15 to 60%. Neither carbachol (10^{-7} M, 10^{-5} M) nor dibutyryl cyclic AMP (10^{-5}-10^{-3} M) affected this enzyme activity, though at the concentrations used, both were capable of stimulating enzyme secretion. Cyclic AMP itself (1 mM) did not affect enzyme activity. It is suggested that the plasma membrane Ca-activated enzyme is not involved in the active Ca extrusion previously reported to occur with use of the various pancreatic secretagogues tested.

3897 EVALUATION OF THE POTASSIUM LOSS THROUGH KEHR'S T TUBE AND THROUGH AN EXTERNAL DUODENAL FISTULA. (Ita.) Bazzocchi, R.; Capizzi, F. D. (Istituto di Clinica Chirurgica Generale e Terapia Chirurgica 1^a, Universita di Bologna, Bologna, Italy). *Clinica (Bologna)* 31(3/4):197-204; 1976.

3898 EFFECT OF TEMPERATURE AND INITIAL CONCENTRATION OF COMPONENTS ON SYNTHESIS OF INTERNUCLEOTIDE BOND CATALYZED BY PANCREATIC RIBONUCLEASE. (Rus.) Kavunenko, A. P.; Kalacheva, T. N.; Tikhomirova-Sidorova, N. S.; Takunitskaia, L. M. (Inst. Macromolecular Compounds, USSR Acad. Sciences, Leningrad, USSR). *Biokhimiia* 40(4):755-761; 1975.

3899 CHANGES OF α-GLYCEROPHOSPHATE DEHYDROGENASE ACTIVITY IN FATTY LIVER OF RATS BY AMINO ACID IMBALANCE. (Eng.) Ogura, M.; Katsunuma, E.; Akabane, T.; Ogawa, S. (Faculty Agriculture, Utsunomiya Univ., Utsunomiya, Japan). *Agric. Biol. Chem.* 40(1):235-236; 1976.

Changes in hepatic α-glycerophosphate dehydrogenase activity were studied in male Wistar rats on a basal diet (8% casein) and on diet with an amino acid imbalance (basal diet plus 0.3% DL-methionine). After 5 and 10 days on either diet, five rats of each group were killed, and the liver weights and enzyme activities were determined. Fatty liver was observed in the animals on the imbalanced diet after 10 days. The specific activity of α-glycerophosphate dehydrogenase was significantly higher after 5 and 10 days in the rats on the imbalanced diet (31.2 nmol/hr/mg protein and 30.5 nmol/hr/mg after 5 and 10 days, resp.) than that in the rats on basal diet (17.3 nmol/hr/mg and 22.3 nmol/hr/mg after 5 and 10 days, resp.), which was at the level of zero time control (20.8 nmol/hr/mg). The total liver activity on the basis of body weight was also significantly higher in the rats on the imbalanced diet (25.1 nmol/hr/mg protein and 25.3 nmol/hr/mg at 5 and 10 days, resp.) than in animals on the basal diet (14.3 nmol/hr/mg and 18.8 nmol/hr/mg at 5 and 10 days, resp.). The elevation of α-glycerophosphate dehydrogenase activity may suggest that the supply of α-glycerophosphate for triglyceride synthesis is increased in this type of fatty liver.

3900 IDENTIFICATION AND CHARACTERIZATION OF A BILE ACID RECEPTOR IN ISOLATED LIVER SURFACE MEMBRANES. (Eng.) Accatino, L.; Simon, F. R. (Departamento de Medicina Interna, Universidad Catolica de Chile, Casilla 114-D, Santiago, Chile). *J. Clin. Invest.* 57(2):496-508; 1976.

The possibility that bile acid receptors are present in liver surface membranes was investigated in Sprague-Dawley rats. Isolated membranes were incubated at 4 C with $[^{14}C]$cholic acid and $[^{14}C]$-taurocholic acid, and membrane-bound bile acid was separated from free bile acid by a rapid ultrafiltration technique through glass-fiber filters. Specific bile acid binding was rapid and reversible and represented approximately 80% of the total bile acid bound to liver surface membranes. Taurocholic acid binding was independent of the medium pH, while cholic acid binding demonstrated an optimum at pH 6.0. Apparent maximal binding capacity and dissociation constant values indicated a large capacity system of receptors with an affinity for bile acids comparable to that of the hepatic transport mechanism. Scatchard analysis of the saturation kinetics, as well as inhibition studies, suggested that bile acids bind to a single and noninteracting class of receptors. In addition, BSP also inhibited cholic acid binding. In contrast, no inhibition was demonstrated with indocyanine green and probenecid. Specific bile-acid binding was enriched and primarily located in liver surface membranes and was found only in tissues involved in bile acid transport. Specific bile acid binding was independent of Na^+, Ca^{2+}, and Mg^{2+} and did not require metabolic energy. In addition, thiol groups and disulfide were not required for activity at the binding site. However, specific bile-acid binding was markedly decreased by low concentrations of proteolytic enzymes and was also decreased by the action of neuraminidase and phospholipases A and C. The results are consistent with the existence of a homogeneous bile acid receptor protein in liver surface membranes. The primary surface membrane location of this receptor, its binding properties, and its ligand specificity suggest that bile acid binding to this receptor may represent the initial interaction in bile acid transport across liver surface membranes.

3901 EFFECTS OF SOME BILE ACIDS ON HEPATIC BLOOD FLOW IN DOGS--WITH REFERENCE TO BILIARY EXCRETION. (Eng.) Yamatake, Y.; Ishikawa, S.; Yanaura, S. (Hoshi Coll. Pharmacy, Shinagawa-ku, Tokyo 142, Japan). *Jpn. J. Pharmacol.* 26(2):273-275; 1976.

The effects of dehydrocholic acid (DHC), ursodeoxycholic acid (UDC), and chenodeoxycholic acid (CDC) on portal and liver tissue blood flow and on bile formation were investigated in male dogs. The three bile acids (3, 10, and 30 mg/kg, i.v.) caused a dose-dependent increase in the volume of biliary outflow. The order of potency was as follows: DHC>UDC>CDC. DHC and UDC, both at 10 mg/kg, caused only a transient and slight change in both portal and liver tissue blood flow. At 30 mg/kg, DHC and UDC moderately increased liver tissue blood flow for at least 30 min, while portal blood flow was transiently decreased by DHC and increased by UDC. CDC caused the strongest responses of hepatic and systemic circulation. CDC at 30 mg/kg produced a significant increase in portal and liver tissue blood flow. These findings suggest that there is no significant relation between the effects of bile acids on biliary excretion and hepatic blood flow.

3902 CYTOCHROME P-450-DEPENDENT HYDROXYLATIONS IN BIOSYNTHESIS AND METABOLISM OF BILE ACIDS. (Eng.) Bjorkhem, I.; Danielsson, H.; Wikvall, K. (Huddinge Hosp., S141 86 Huddinge, Sweden). *Biochem. Soc. Trans.* 3(6):825-828; 1975.

Hydroxylations in the formation and metabolism of bile acids were investigated in reconstituted systems from liver microsomal fractions of male Sprague-Dawley rats, consisting of partially purified cytochrome P-450 and NADPH-cytochrome P-450 reductase. The microsomal fraction of homogenates was isolated by centrifugation of the 20,000 *g* supernatant of liver homogenate at 100,000 *g* for 1 hr. The 7α-hydroxylation of cholesterol was the major rate-limiting step in the overall conversion of cholesterol into bile acids. The reaction exhibited characteristics of a cytochrome P-450-dependent hydroxylation. It showed the unique properties of the different hydroxylations in the biosynthesis and metabolism of bile acids. The reaction was stimulated by biliary drainage and was inhibited by feeding of various bile acids. In the 12α-hydroxylation, the main substrate was 7α-hydroxy-4-cholesten-3-one. The reaction was catalyzed by a reconstituted system. The extent of inhibition by CO was markedly lower than that of other cytochrome P-450-catalyzed reactions. The reaction was stimulated by starvation. The preferred substrates in microsomal 26-hydroxylation are 5β-cholestane-3α,7α-diol, and 5β-cholestane-3α,7α,12α-triol, and the reaction was catalyzed by a reconstituted system. In both intact microsomal fractions and reconstituted systems, 26-hydroxylation was accompanied by 25-hydroxylation. The mitochondrial 26-hydroxylation depended on intramitochondrially generated NADPH and was a mono-oxygenase reaction, which was inhibited by CO. The properties of the hydroxylations in the biosynthesis of bile acids are such that it appears difficult to reconcile these with a single catalytic system.

3903 EFFECTS OF TAURODIHYDROFUSIDATE, A BILE SALT ANALOGUE, ON BILE FORMATION AND BILIARY LIPID SECRETION IN THE RHESUS MONKEY.

(Eng.) Beaudoin, M.; Carey, M. C.; Small, D. M. (Hosp. Notre-Dame, Montreal, Canada). *J. Clin. Invest.* 56(6):1431-1441; 1975.

The biliary secretion of sodium taurodihydrofusidate (TDHF), a bile salt analogue, and its influence on bile formation and biliary lipid secretion were studied in female rhesus monkeys. Unanesthetized monkeys, prepared with a total biliary fistula, were allowed to reach a steady bile salt secretion rate before each study. In three animals (group I), a 0.63% solution of $[^{14}C]$TDHF (2-4 μCi) was infused i.v. Most of the compound was secreted rapidly in bile, which was chemically unchanged. The biliary secretion of this drug produced a twofold increase in bile flow; however, the bile salt output was markedly reduced during the infusion. In spite of this reduction, the phospholipid output remained essentially unchanged, whereas the cholesterol output increased almost twofold. In five other animals (group II), the effect of TDHF on the bile salt secretion was further investigated by an i.v. infusion of $[^{14}C]$-taurocholate followed by a simultaneous infusion of 0.48% $[^{14}C]$taurocholate (3 μCi; 200 μmol/hr, 4 hr) and 1.11% TDHF (3 μCi; 200 μmol/hr, 4 hr). When TDHF was added to the infusate, a reduction in the $[^{14}C]$taurocholate output and a progressive rise in the plasma $[^{14}C]$taurocholate concentration were observed in each animal. An analysis of the data in both groups indicated that: (a) TDHF interfered with bile salt secretion into the biliary canaliculi; (b) TDHF induces a greater secretion of biliary water than was observed with bile salts, an effect consistent with a stimulation of the bile salt-independent canalicular flow; and (c) at similar 3α-hydroxysteroid secretion rates, TDHF caused a significant increase in cholesterol secretion compared to that induced by bile salt. This finding suggests that TDHF affects cholesterol metabolism or secretion in a way that is distinct from bile salts. Thus, the solubilization of biliary lipids in mixed micelles, although essential, is only one of the factors that determine their secretion into bile.

3904 STORAGE OF IRON AS FERRITIN IN THE LIVER OF THE PROTEIN-DEFICIENT RAT. (Eng.)

Stanton, M.; Ramsay, W. N. M. (Dept. Biochemistry, Univ. Edinburgh, Edinburgh EH9 1QH, U.K.). *Biochem. Soc. Trans.* 3(6):939-940; 1975.

Experiments were conducted to determine whether the protein-deficient rat maintains more ferritin protein or produces molecules with a higher average iron content. Male and female rats were fed for 5 weeks on diets lacking or containing 22% protein as casein. All diets contained 3-4 mg ferritin. More ferritin iron was found in the livers of protein-deficient male rats (2 experiments: 1.81 and 1.47 mg/liver) than in animals fed a casein-containing diet (1.19 and 1.17 mg, resp.; $p<0.01$ and $p<0.05$, resp.). No significant difference was seen with females. The livers of protein-deficient males contained ferritin with 20-30% more iron atoms per molecule (2509 and 2026 atoms/molecule) than ferritin from the livers of animals on casein-containing diets (2067 and 1489 atoms/molecule, $p<0.01$ and $p<0.05$, resp.). This difference was not observed in the females. Although the level of ferritin protein fluctuated from one experiment to another, it was clear that in both sexes the amount of ferritin protein was well maintained in the face of severe protein deficiency. It appears that male protein-deficient rats may respond at least partly to the demand for increased iron storage by increasing the average iron content of ferritin molecules. The results suggest that the behavior of ferritin is different from that of secreted proteins.

3905 CARBOHYDRATE METABOLISM IN PERFUSED LIVERS OF ADRENALECTOMIZED AND STEROID-REPLACED RATS.

(Eng.) Exton, J. H.; Miller, T. B., Jr.; Harper, S. C.; Park, C. R. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *Am. J. Physiol.* 230(1):163-170; 1976.

Changes in glucose, glycogen, and certain metabolite levels were studied in livers from normal, adrenalectomized, and glucocorticoid-restored Sprague-Dawley rats perfused with lactate or fructose, to locate the sites at which glucocorticoids stimulate gluconeogenesis and glycogen synthesis in the liver. In livers from fasted rats perfused with bicarbonate buffer containing bovine albumin and erythrocytes, adrenalectomy decreased glycogen levels and glucose production, impaired the incorporation of ^{14}C from 20 mM $[^{14}C]$lactate into glucose or glycogen, and decreased the activity of the active (I) form of glycogen synthase. Cortisol (2.5 mg, s.c., 24, 16, and 4 hr prior to perfusion) treatment restored gluconeogenesis after 1 hr and glycogen synthesis after 2 hr. Adrenalectomy did not alter the production of glucose or lactate or the levels of gluconeogenic intermediates in livers from fasted rats perfused with 20 mM fructose, but reduced the forma-

LIBRARY U.

tion of glycogen from this substrate. Adrenalectomy increased the levels of lactate and pyruvate in livers from fasted rats perfused with lactate and decreased the levels of *P*-pyruvate and subsequent intermediates in the gluconeogenic pathway. These changes were reversed by cortisol treatment. It is concluded that glucocorticoids support gluconeogenesis and glycogen synthesis in livers from fasted rats primarily by facilitating a reaction(s) located between pyruvate and *P*-pyruvate in the gluconeogenic pathway and by promoting the conversion of (inactive or active) glycogen synthase.

3906 HEPATIC ACCUMULATION OF VITAMIN D_3 AND 25-HYDROXYVITAMIN D_3. (Eng.) Rojanasathit, S.; Haddad, J. G. (Jewish Hosp. St. Louis, St. Louis, MO). *Biochim. Biophys. Acta* 421(1):12-21; 1976.

Experiments were conducted to determine whether serum 25-hydroxycholecalciferol (25-OH-vitamin D_3) directly influences hepatic calciferol 25-hydroxylase or simply reflects its activity. Concomitant i.v. administration of 25-hydroxycholecalciferol and [^{3}H]-vitamin D_3 to vitamin D-depleted Wistar rats did not affect the conversion of [^{3}H]vitamin D_3 to 25-OH-[^{3}H]vitamin D_3, as indicated by a serum 25-OH-[^{3}H]vitamin D_3 content at 3 and 24 hr identical to those observed in animals receiving [^{3}H]vitamin D_3 alone. Similarly, pre-dosing with 25-OH vitamin D 24 hr earlier did not affect the conversion. Co-administration to vitamin D-depleted rats of vitamin D_2 or D_3, at 200-fold higher doses than a control group receiving tracer [^{3}H]vitamin D_3 alone, resulted in serum 25-OH vitamin D levels that were 15- to 20-fold higher than the control. These results indicate a similar metabolic fate for synthetic and natural vitamin D in rats, and the ability of increased substrate to overwhelm hepatic constraints on 25-OH vitamin D production. Following the i.v. administration of 25-OH-[^{3}H]vitamin D_3 to vitamin D-depleted rats, hepatic ^{3}H content decreased in parallel with serum radioactivity. Hepatic accumulation of i.v. administered vitamin D_3 ([^{14}C]vitamin D_3), alone or with 25-OH-[^{3}H]vitamin D_3, by vitamin D-depleted rats, revealed a marked preference for vitamin D_3; the hepatic accumulation of [^{14}C]vitamin D_3 increased to 35% of the dose by 45 min, at which time 25-OH-[^{3}H]vitamin D_3 hepatic content was sevenfold less, and decreasing. Chromatography of extracts of hepatic subcellular fractions revealed more [^{14}C]vitamin D_3 than 25-OH-[^{3}H]vitamin D_3 in the microsomes, the reported site of calciferol 25-hydroxylase. Circulating 25-OH vitamin D, therefore, has comparatively minimal potential for hepatic accumulation. Product inhibition of the calciferol 25-hydroxylase must, therefore, result from recently synthesized hepatic 25-OH vitamin D, and is not affected by exogenous 25-OH vitamin D_3.

3907 CLASS-ORGANIZATION OF THE HEPATOCYTES. EARLY CHANGES FOLLOWING ACUTE INTOXICATION BY DRUGS AND POISONS. (Eng.) Tongiani, R.; Malvaldi, G.; Chieli, E. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* Bertelli, A., ed. (Basel: S. Karger): pp. 27-37; 1975.

Early changes in cell class patterns of hepatocytes of male Sprague-Dawley rats were investigated following acute intoxication by drugs and poisons. Rats were given thioacetamide (10 and 25 mg/kg body weight, i.p.), α-amanitin (50 and 100 μg/100 g body weight, i.p.), phalloidin (40 μg/100 g body weight, i.p.), and phenobarbital (7 mg/100 g body weight/day, i.p.). The weight of the total solid constituents of the hepatocytes was determined in single cells isolated and suspended in anhydrous glycerol. The cell dry mass was determined by a microinterferometric integrating apparatus. There was a marked decrease in the number of classes within 1.5 hr following administration of 25 mg thioacetamide and within 3 hr following 10 mg thioacetamide, due to the disappearance of the three heaviest classes. Three classes disappeared following both doses of α-amanitin. After administration of both poisons, there was a shift of hepatocytes to the lighter classes. The presence of cells in the intervals among the classes, particularly 3 hr after phalloidin administration, represented the most notable change in class pattern. Phenobarbital injection was followed by a marked increase in the number of classes, which reached 14 after 1 day versus 12 in the controls, and 21 after 4 days. It is concluded that the usefulness of this technique for assessing early hepatocyte damage was demonstrated.

3908 LIVER ALDEHYDE AND ALCOHOL DEHYDROGENASE ACTIVITIES IN RAT STRAINS GENETICALLY SELECTED FOR THEIR ETHANOL PREFERENCE. (Eng.) Koivula, T.; Koivusalo, M.; Lindros, K. O. (Dept. Medical Chemistry, Univ. Helsinki and Res. Lab. State Alcohol Monopoly (Alko), Helsinki, Finland). *Biochem. Pharmacol.* 24:1807-1811; 1975.

Liver aldehyde and alcohol dehydrogenase activities were investigated in rat strains raised by genetic selection for either high (AA strain) or low (ANA strain) voluntary ethanol consumption. The soluble, mitochondrial, and microsomal fractions prepared from male and female liver tissues of both strains were examined spectrophotometrically. Liver alcohol dehydrogenase activity was higher in both sexes in the ANA strain ($p<0.005$) than the AA strain. With propionaldehyde (4.5 mM) as substrate, female rats of the AA strain had significantly higher aldehyde dehydrogenase activity in both mitochondrial ($p<0.025$) and microsomal ($p<0.005$) fractions than did females of the ANA strain, but in the soluble fraction, the aldehyde dehydrogenase activity was higher ($p<0.025$) in ANA rats. The total activity in female rats was higher ($p<0.05$) in the AA strain. In male rats, differences were significant ($p<0.025$) only in the microsomal fraction in which AA rats had higher activity. With acetaldehyde (0.5 mM) as substrate, aldehyde dehydrogenase activity was higher in the soluble fraction prepared from livers of both female ($p<0.005$) and male ($p<0.025$) ANA rats. In the microsomal fraction, AA rats had higher activity ($p<0.005$) in both sexes than ANA rats. The NAD-dependent acetaldehyde utilization was sig-

:icantly higher in preparations from AA rats than
those from ANA rats, both in females ($p<0.001$) and
males ($p<0.05$), with 0.40 mM acetaldehyde as sub-
:ate. The higher alcohol dehydrogenase and lower
lehyde dehydrogenase activity in rat livers of the
ianol-avoiding ANA strain may contribute to the
eviously found higher acetaldehyde levels in blood
l liver of rats of this strain after ethanol admin-
:ration.

9 THE EFFECT OF INHIBITORS OF ALCOHOL METABOLISM ON THE CHANGES IN THE HEPATIC ROSOMAL METABOLISM OF FOREIGN COMPOUNDS PRODUCED A SINGLE DOSE OF ETHANOL IN THE RAT.

(Eng.)
nt, L.; Powis, G. (Dept. Pharmacology, Glasgow
v., Glasgow G12 800, Scotland). *Br. J. Pharma-*
. 56(3):376P-377P; 1976.

empts were made to distinguish between the
ect effects of ethanol and the effects resulting
m the metabolism of the ethanol on the hepatic
rosomal metabolism of foreign compounds in unan-
hetized rats. Acetaldehyde oxime (200 mg/kg,
.) alone produced no significant change in ani-
e hydroxylation, but caused an increase in ani-
e hydroxylation in animals fed ethanol
mmol/kg) from 9.4 ± 0.4 to 21.9 ± 1.3 nmol/mg/30
($p<0.01$). Acetaldehyde oxime produced a de-
ase in aminopyrine demethylation of a magnitude
ilar to that caused by ethanol itself, although
re was no additive effect when both compounds
e administered together. Pyrazole (200 mg/kg,
.) produced an increase in aniline hydroxylation
a decrease in aminopyrine demethylation.
taldehyde (22 mmol/kg, fed 24 and 18 hr before
preparation of the microsomal fraction) had no
ect on aniline hydroxylation, but produced a de-
ase in aminopyrine demethylation from 105.3 to
5 nmol/mg/30 min ($p<0.01$). Disulphiram
) mg/kg, i.p.) reduced aminopyrine demethylation
70.9 nmol/mg/30 min ($p<0.01$), and also potenti-
l the decrease in aminopyrine demethylation in
s fed only half the previous dose (i.e., half of
mol/kg) of acetaldehyde to 37.9 ± 5.1 nmol/mg/30
($p<0.05$). It is concluded that the increase
niline hydroxylation produced by the administra-
ı of ethanol is a consequence of the ethanol
elf, while the decrease in aminopyrine demethyla-
ı is a consequence of the metabolism of ethanol
cetaldehyde.

) EFFECT OF ETHANOL ON UTILIZATION OF PLASMA FREE FATTY ACIDS FOR LIVER TRIACYL-EROL SYNTHESIS AND ITS RELATION TO HEPATIC TRIA-LYCEROL ACCUMULATION IN RATS.

(Eng.) Johnson,
Hernell, O.; Olivecrona, T. (Dept. Chemistry,
. Umea, S-901 87 Umea, Sweden). *Lipids* 10(12):
-769; 1975.

effects of ethanol (2.00, 3.75, or 6.00 g/kg
weight) on the utilization of plasma free fatty
s for liver triacylglycerol synthesis and its
tion to hepatic triacylglycerol accumulation
investigated in female Sprague-Dawley rats.
als of experiment I were given 0.5 ml of a
y acid (^{14}C-oleic acid) albumin complex (containing 10 x 10^6 cpm/ml). Rats given 3.75 or 6 g of ethanol were markedly ataxic between 0 and 6 hr. In contrast, rats given 2 g ethanol could not be distinguished in behavior from control rats. Six hours after the ethanol was administered, all rats in experiment I had increased liver triacylglycerol concentrations compared with the controls ($p<0.01$). The groups given 3.75 and 6 g of ethanol had similar, high triacylglycerol concentrations and high plasma ethanol concentrations. The groups ($p>0.05$) not given fatty acid showed no statistically significant difference in liver triacylglycerol concentration. After 6 hr, the liver triacylglycerol concentration decreased in the group given 2 g ethanol. From 6-11 hr, the mean values of the liver triacylglycerol concentrations increased in both the 3.75- and 6-g groups. At 11 hr, the rats given 3.75 g ethanol had little or no ethanol left in the blood, while the rats given 6 g still had a high plasma ethanol concentration. Between 11 and 16 hr, the liver triacylglycerol concentration did not decrease in the group given 6 g, while it did decrease in the group given 3.75 g ($p<0.05$). The results confirm those of a previously published report by the authors that after a lag period of several hours, ethanol increased the plasma triacylglycerol concentrations, probably by increasing liver triacylglycerol secretion.

3911 THE EFFECTS OF ETHANOL AND OF A MIXTURE OF ETHANOL AND HIGHER-ALCOHOLS ON THE ACTIVITY OF MICROSOMAL ANILINE HYDROXYLASE IN THE RAT LIVER.

(Eng.) Auty, R. M.; Branch, R. A. (Univ. Bristol Medical Sch., University Walk, Bristol BS8 1TD, U.K.). *J. Pharm. Pharmacol.* 28(2):160-161; 1976.

The influence of chronic administration of a cocktail of n-propyl, n-butyl, and iso-amyl alcohol on the activity of microsomal aniline hydroxylase in the livers of male Wistar rats was compared with that of ethanol alone. Six animals received 10% ethanol (volume/volume) in water for 28 days followed by 20% ethanol for 42 days; six animals received a cocktail of ethanol (10% for 28 days and 20% for 42 days in water), n-propanol (804 mg/l), n-butanol (3.24 mg/l), and iso-amyl alcohol (2.45 g/l). Ethanol alone resulted in a 49% increase in microsomal protein concentration and a 49.5% increase in aniline hydroxylase activity. The cocktail resulted in an 81% increase in microsomal protein concentration and a 41% increase in aniline hydroxylase activity. Aniline hydroxylase activity per gram of microsomal protein remained constant after treatment with ethanol, indicating an increase in functioning hepatic mass rather than an increase in enzyme activity. The aniline hydroxylase activity was less marked after the treatment with the cocktail than either after ethanol alone or control. The inability of the additional microsomal protein resulting from the administration of the cocktail to hydroxylate aniline suggests the possibility of specific enzyme induction.

3912 DEPENDENCE ON DOSE OF THE ACUTE EFFECTS OF ETHANOL ON LIVER METABOLISM IN VIVO.

(Eng.) Guynn, R. W.; Pieklik, J. R. (Univ. Texas

Medical Sch. Houston, Houston, TX 77025). *J. Clin. Invest.* 56(6):1411-1419; 1975.

The effects of various doses of ethanol on liver intermediary metabolism was tested *in vivo* in unanesthetized male Wistar rats. Ethanol was given i.p. in doses of 0.69, 1.7, or 3.0 g/kg in equal volumes (20 ml/kg) to three groups of animals. The liver was freeze-clamped 120 min after injection, and multiple metabolites were measured in the perchloric acid extract of the tissue. Each group showed a significantly different pattern of metabolites, redox states, and phosphorylation potentials, although the rate of ethanol disappearance, at least between the two highest dose groups, was not significantly different. The mitochondrial free $[NAD^+]/[NADH]$ ratios and the cytoplasmic free $[NADP^+]/[NADPH]$ ratio were most reduced with the lowest dose of ethanol and they became progressively more oxidized with increasing dose. Once established, the differences in these ratios between the groups tended to persist with time, relatively independent of the concentration of ethanol. In a somewhat different pattern, the phosphorylation potential ($[ATP]/[ADP][P_i]$) remained at the control level in the low-dose group but was significantly elevated in the two higher-dose groups. The results indicate distinct and complicated dose-dependent patterns of intermediary metabolism that cannot be explained completely by any one hypothesis but that imply significant dose-dependent effects of ethanol upon intermediary metabolism, not directly related to NADH production. It is suggested that the amount of ethanol ingested at one time may be an important variable in the pathology of alcoholism.

LIBRARY U. [illegible]

3913 GLYCYLPROLYL β-NAPHTHYLAMIDASE ACTIVITIES IN SERUM, LIVER AND KIDNEY OF RATS IN CHRONIC CARBON TETRACHLORIDE INTOXICATION.

(Eng.) Hino, M.; Fuyamada, H.; Nagatsu, T.; Kurokawa, S.; Okuyama, S. (Sch. Dentistry, Aichi-Gakuin Univ., 2-11 Suemori-dori, Chikusa-ku, Nagoya 464, Japan). *Clin. Chim. Acta* 67(1):103-105; 1976.

Glycylprolyl β-naphthylamidase activities were measured in the serum, liver, and kidney of rats with carbon tetrachloride-induced (0.15 ml/100 g of a 50% solution, twice weekly) hepatic injury to determine if the elevated serum levels of this enzyme, seen in hepatobiliary diseases, are caused by release of this enzyme. Serum glycylprolyl β-naphthylamidase activity increased about 1.8-fold at 1 week of CCl_4 treatment, about 2.5-fold at 8 weeks, and remained high throughout the 16-week observation period. In contrast, the activity in the liver decreased significantly at 2 hr after the first CCl_4 administration, and after 8 weeks, it was about 67% of the normal value. Although the glycylprolyl β-naphthylamidase activity was high in the kidney, it did not change significantly during the first 12 weeks; a slight but significant decrease occurred at 16 weeks. The results indicate that the elevated serum levels of glycylprolyl β-naphthylamidase in hepatobiliary injury may be mostly derived from the liver.

3914 REGENERATION IN RAT LIVER INJURED BY CARBON TETRACHLORIDE.

(Eng.) Rosenkranz, E.; Charters, A. C., III; Orloff, M. J. (Univ. California, San Diego, Sch. Medicine, La Jolla, CA). *Surg. Forum* 26:411-412; 1975.

Liver regeneration was studied after 70% hepatectomy in 20 male Long-Evans rats treated with 10% CCl_4 (1 ml, i.m., on alternate days, 20 doses). The animals were given ^{3}H-thymidine (100 μCi, i.p.) 24 hr after hepatectomy, and were killed 2 hr later. Normal livers from 15 control animals showed no significant cellular mitotic activity prior to hepatectomy. The CCl_4-injured livers demonstrated active regeneration, with a mean of 9.2 mitoses per 100 high-power fields (hpf). This mitotic activity was confined to islands of relatively healthy-appearing hepatocytes. After hepatectomy, there was a marked increase in the indices of regeneration in both groups. The regenerative response to partial hepatectomy in the CCl_4-injured liver was significantly less than that in the normal liver (56.8 mitoses/100 hpf, 1,089 labeled nuclei/100 hpf, and 4,804 counts/min thymidine uptake in normal rats and 31.9 mitoses/100 hpf, 495 nuclei/100 hpf, and 1,103 counts/min in the CCl_4-treated rats). The periportal distribution of mitotic activity in the injured liver prior to and after hepatectomy suggests that regeneration is influenced by a humoral factor in portal blood.

3915 INHIBITION OF DRUG METABOLIZING ENZYMES BY DIAZEPAM IN RAT LIVER.

(Eng.) Vorne, M.; Idanpaan-Heikkila, J. (Dept. Pharmacology, Univ. Oulu, Oulu, Finland). *Experientia* 31(8):962-963; 1975.

The effect of diazepam on the activity of drug metabolizing enzymes was studied in 24 male Sprague-Dawley rats. The possibility that diazepam may stimulate its own metabolism and thus explain the development of tolerance to it was also studied. One group of six rats received diazepam in the diet (100 mg/day for 6 days). Two other groups were given phenobarbital or 3,4-benzpyrene (80 and 20 mg/kg, resp.) for the same length of time, and the remaining six animals served as controls. Diazepam had no significant effect on the content of cytochrome P-450 or *N*-demethylation on methylaniline. Diazepam decreased the oxidation of hexobarbital to 67% of controls and the reduction of *p*-nitrobenzoic acid to 59% of controls. 3,4-Benzpyrene had no effect on diazepam metabolism, although phenobarbital increased the rate of metabolism of diazepam (14.92 nmol of substrate and metabolites recovered after incubation) over that of controls (28.10 nmol). Diazepam had no effect on its own metabolism; this is similar to previous findings with prazepam but different from findings with chlordiazepoxide. It is likely that the benzodiazepines differ from each other with regard to their effect on drug metabolizing enzymes.

3916 EFFECTS OF CYCLOHEXIMIDE ON PROTEIN DEGRADATION AND GLUCONEOGENESIS IN THE PERFUSED RAT LIVER.

(Eng.) Woodside, K. H.

(Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Biochim. Biophys. Acta* 421(1):70-79; 1976.

Intracellular amino acid levels were measured in perfused Lewis rat livers following treatment with cycloheximide to determine the role of amino acids in the inhibition of proteolysis by cycloheximide. Cycloheximide at concentrations above 18 μM produced a 93% inhibition of total protein synthesis measured by valine incorporation in the perfused liver. Rates of protein degradation were estimated by perfusing livers prelabeled *in vivo* with L-[1-^{14}C]-valine with medium containing 15 mM L-valine. Thus, labeled valine released from liver protein during perfusion was greatly diluted, and reincorporation of label was minimized. Cycloheximide at 18 μM inhibited protein degradation by over 60% after a delay of 15-20 min. Associated with these effects were dose-dependent increases in the rates of glucose and urea production. Glucose production increased threefold, from 0.54 in control to 1.85 μmol/min/100 g rat in cycloheximide-treated livers. Urea production increased from 0.24 to 0.62 μmol/min/100 g rat. No changes in liver glycogen or cyclic AMP content were observed. The data suggest that inhibition of protein synthesis provides an increased availability of intracellular amino acids and that many of these are rapidly degraded, yielding urea and glucose. This is supported by the fact that intracellular alanine levels were significantly increased following cycloheximide treatment. It is possible that the inhibition of protein degradation by cycloheximide is due to altered intracellular pools of amino acids or their metabolites.

3917 EFFECT OF PREGNENOLONE-16α-CARBONITRILE ON THE RAT LIVER. (Eng.) Kourounakis, P.; Szabo, S.; Selye, H. (Institut de medecine et de chirurgie experimentales, Universite de Montreal, C. P. 6128, Montreal 101, Quebec, Canada). *Arzneim. Forsch.* 26(1):74-75; 1976.

The effect of pregnenolone-16α-carbonitrile (PCN, 20 μmoles/100 g, p.o., twice daily for 3 days) on the livers of female Charles River CD rats was investigated. PCN caused a 17% increase in liver weight, a 26.3% increase in ATP, a 12.3% increase in protein content, a 76% increase in total lipid constituents, and a 16.7% increase in phospholipids. The increased ATP concentrations show that PCN influences the synthesis of energy-yielding metabolites; this increase may be related to the enhanced bile flow observed after PCN treatment. PCN did not alter body weight, or water, ash, triglyceride, or cholesterol levels in the liver.

3918 EFFECTS OF SECRETIN AND CHOLECYSTOKININ ON RELATIVE COMPOSITION OF HEPATIC BILE IN RHESUS MONKEYS. (Eng.) Gardiner, B. N.; Conaway, C.; Small, D. M. (Univ. California San Francisco, Sch. Medicine, San Francisco, CA). *Surg. Forum* 26:437-439; 1975.

The influence of cholecystokinin and secretin on the relative composition and ability of bile to solubilize cholesterol was studied in three cholecystectomized female rhesus monkeys. Increasing i.v. doses of secretin increased the amount of bile salt present relative to the amount of both cholesterol and phospholipid; a maximal response to secretin was obtained at 5 U/kg/hr, changing the relative composition from 82.9% bile salt to 89.3%, from 2.6% cholesterol to 1.9%, and from 14.3% phospholipid to 8.9%. Hourly secretion of bile salt from the liver was increased 149% above control by secretin, and phospholipid secretion was increased 41%. These changes were accompanied by a steadily increasing output of pancreatic bicarbonate. Increasing doses of cholecystokinin also produced a linear change in the relative composition of bile; the maximal response occurred at 2.3 U/kg/hr, increasing the relative proportion of bile salt from 82.4 to 88.1% and decreasing the proportion of phospholipid from 15.5 to 9.8%. At this concentration of cholecystokinin, bile salt secretion was increased 69% above control; cholesterol, 51.6%, and phospholipid, 32.2%. These changes were accompanied by a linear increase in pancreatic protein secretion. The changes in the relative composition of bile produced by secretin, and possibly by cholecystokinin, are potentially important, since they improve the cholesterol-holding capacity of bile.

3919 GLUTATHIONE REDUCTASE ACTIVITY IN SERUM AND LIVER TISSUE OF HUMAN AND RAT WITH HEPATIC DAMAGE. (Eng.) Kumata, H.; Wakui, K.; Suzuki, H.; Sugawara, T.; Lim, I.; Otsuki, M.; Ozeki, T.; Miura, K.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 116(2):127-132; 1975.

Glutathione reductase activity of both serum and liver tissue homogenates was measured in 4 normal controls and in 29 patients with hepatic parenchymatous diseases. The results were compared with those from experiments with male Donryu rats in which hepatic damage had been produced by administration of CCl_4 (0.02 mg/100 g body weight, i.p.). The human specimens were taken by needle biopsy at laparoscopy. In the four healthy subjects, liver glutathione reductase (LGR) was 6.0 ± 2.0 U, which showed a statistically significant correlation with liver GOT (LGOT) and liver GPT (LGPT) ($p<0.01$ in both). The LGR was 29.6 ± 21.1 U in 14 patients with acute hepatitis, 13.5 ± 5.5 U in 11 patients with chronic hepatitis, and 22.0 ± 12.5 U in 4 patients with liver cirrhosis. Statistically significant correlations were found between LGR and LGOT in acute hepatitis ($p<0.1$) and LGR and LGPT in liver cirrhosis ($p<0.1$). In CCl_4-treated rats, the SGR activities at 6, 12, 24, and 36 hr after injection were 102.8 ± 10.1, 86.4 ± 23.4, 64.0 ± 10.1, and 52.4 ± 8.6 U/ml, resp. The LGR activities in CCl_4-treated rats were 93.6 ± 6.0, 94.8 ± 8.2, 92.0 ± 13.4, and 83.4 ± 9.6 U/mg at 6, 12, 24, and 36 hr, resp., after injection. A significant correlation was found between LGR and LGOT activities at 6 hr after CCl_4 injection ($p<0.05$). The results demonstrate that the mechanism of the elevation of SGR in liver damage is different from that of the leaking enzymes that are liberated from the liver in liver damage. It is also noted that changes in glutathione reductase activities in serum and liver occur in the early stages of liver damage.

3920 BLOOD VOLUME PARTITION AFTER ACUTE CHOLESTASIS IN THE RAT. (Eng.) Aarseth, P.; Aarseth, S.; Bergan, A. (Inst. Physiology, Univ. Oslo, Karl Johans Gate 47, Oslo 1, Norway). *Eur. Surg. Res.* 8(1):61-70; 1976.

A method involving ^{51}Cr-labeling of RBC and ^{125}I-labeling of serum albumin and rapid freezing of intact rats was used to evaluate the blood content in liver, spleen, and gastrointestinal (GI) tract in cholestatic male Wistar rats. For comparison, the lungs were also examined. After 4 days of cholestasis, experimentally induced by bile duct ligation, the animals were hypovolemic; their blood volume was 12.8 ml and large vessel hematocrit was 47%, as opposed to 14.5 ml and 44%, resp., in sham-operated controls. At this time, the livers of the sham-operated animals contained 2.1 ml of blood or 14.6% of their total blood volume; the livers of cholestatic animals contained 1.9 ml ($p<0.036$), a small increase in absolute terms. After 7 days of cholestasis, the liver contained 2.6 ml of blood, an increase in both relative ($p<0.016$) and absolute ($p<0.009$) terms. The GI blood content was increased over the control level (0.7 ml) at both 4 days (0.8 ml) and 7 days (0.9 ml, $p<0.036$), while the splenic blood content was unchanged or slightly reduced. Four days after the induction of cholestasis, when the animals were dehydrated, the pulmonary blood volume was reduced by 0.8 ml ($p=0.001$). When the total blood volume was normalized 3 days later, the pulmonary blood volume was increased by 0.3 ml but was still markedly reduced compared to controls ($p=0.04$). The total body hematocrit, calculated from the distribution volumes for labeled RBC and plasma albumin, changed in accordance with the measured hematocrit in large vessel blood. In the GI tract and lungs, the dynamic hematocrits increased relative to the large vessel hematocrit after 4 and 7 days of cholestasis ($p<0.018$). The liver hematocrit was high in the sham-operated animals (103% of total body hematocrit), but decreased markedly (87-88% of total body hematocrit, $p=0.002$) in the cholestatic groups. In sham-operated animals, the dynamic hematocrit of the spleen was 172% of the total body hematocrit, and in the cholestatic animals it was 141 and 152% on days 4 and 7, resp. It is suggested that during cholestasis, the depot function of the splanchnic vessels is disturbed. This might be one factor in the development of the hepatorenal syndrome.

3921 EFFECT OF PHOSPHOLIPID ON THE RELEASE OF BETA-LIPOPROTEIN IN OROTIC ACID-INDUCED FATTY LIVER. (Eng.) Negishi, I.; Aizawa, Y. (Tokyo Coll. Pharmacy, Sinjuku-ku, Tokyo, Japan). *Chem. Pharm. Bull. (Tokyo)* 23(9):1928-1931; 1975.

The content of liver lipids and protein and of serum β-lipoprotein was determined in female Wistar rats fed orotic acid and in controls. Further, the effect of phosphatidylcholine on the release of β-lipoprotein from liver slices into the incubation medium was examined in both groups. Liver glycerides were increased 1,030% in rats fed orotic acid over controls, but liver phospholipid was only 68% of controls, and protein was only 76.8% of controls. A 50% depression of the content of serum β-lipoprotein was observed in rats fed orotic acid. The release of β-lipoprotein from liver slices decreased when orotic acid was added to the diet. This decrease was partly restored by the addition of phosphatidylcholine (50 μg P/ml). When liver slices were pretreated with phospholipase C (250 μg/ml), the amount of released β-lipoprotein increased in both control and orotic acid-fed rats. By the addition of phosphatidylcholine, the treated liver slices from orotic acid-fed rats released the same amount of lipoprotein as controls. Because phosphatidylcholine appears to take part in the release of β-lipoprotein, fatty liver induced by orotic acid must have resulted from the impaired phosphatidylcholine synthesis in the liver.

3922 INDUCTION OF CHRONIC LETHAL AUSTRALIA ANTIGEN HEPATITIS IN MICE. (Eng.) Johnson, L. A.; Wirostko, E. (Columbia Univ. Coll. Physicians Surgeons, 630 West 168th St., New York, NY 10032). *Am. J. Pathol.* 82(1):85-94; 1976.

A possible cause of the uveitis in six patients havin concurrent chronic iridocyclitis and chronic active hepatitis with serum Australia antigen (AA) was investigated. The aqueous humor from each patient was analyzed for AA, passed through 220-mμ filters, and inoculated directly into the livers of male CD-1 mice. The animals were observed for spontaneous mortality for 12 months, at which time the remaining animals were sacrificed. The livers of all animals were examined for hepatitis and AA. Although the aqueous humor from only one patient contained AA, all six aqueous specimens produced a lethal viral hepatitis-like disease with liver AA. The results suggest that the six positive aqueous specimens contained a viral infectious agent, which may have been the core of the Dane particle, and that the mouse is suitable for the laboratory investigation of type B hepatitis by the technique described.

3923 HEPATIC KUPFFER CELL DYSFUNCTION DURING HEMORRHAGIC SHOCK. (Eng.) Loegering, D. J.; Saba, T. M. (Albany Medical Coll., Albany, NY 12208). *Circ. Shock* 3(2):107-113; 1976.

Humoral and cellular aspects of reticuloendothelial system (RES) function were studied in anesthetized male dogs during hemorrhagic shock. Dogs that were subjected to the hemorrhagic shock to a mean arterial blood pressure of 40 mm Hg, showed a 65% depression in phagocytic index at both 5% and 30% uptake of the maximal shed blood volume. As demonstrated by a standard colloid clearance technique, this depression in RES function was due primarily to a reduction in hepatic Kupffer cell phagocytosis and, to a lesser extent, to a reduction in spleen uptake of the injected colloid. Localization of the colloid in the lung increased at 5% uptake and did not differ significantly from control at 30% uptake of the maximal shed volume. Circulating opsonic activity showed a large (37%) decrease at 5% uptake and returned to prehemorrhage levels at the 30% uptake point, even though continued RES depression existed. These data suggest that RES function depression during the early stages of hemorrhagic shock may be mediated, in part, by a depletion of circulating opsonic activity. In contrast, other factors, such as cellular disturbances and/or circulatory alterations appear to mediate Kupffer cell dysfunction during the later stages of hemorrhagic shock.

3924 SPLENIC ARTERY LIGATION IN SELECTED PATIENTS WITH HEPATIC CIRRHOSIS AND IN SPRAGUE-DAWLEY RATS. (Eng.) Witte, C. L.; Witte, M. H.; Renert, W.; O'Mara, R. E.; Lilien, D. L. (Univ. Arizona Coll. Medicine, Tucson, AZ). *Surg. Gynecol. Obstet.* 142(1):1-12; 1976.

The effects of splenic artery ligation were studied in Sprague-Dawley rats and in eight selected symptomatic patients with hepatic cirrhosis. Twenty-five animals underwent ligation; five rats were sacrificed at weekly intervals for 1 month and the final five at 3 months. Fifteen other rats served as sham-operated or unoperated controls. Ligation in rats induced splenic infarction, reduced functional splenic mass, transiently raised platelet and reticulocyte counts, and was without local complications. In seven selected patients with cirrhosis and prominent splenomegaly, the splenic artery was markedly enlarged, splenic arterial flow was greatly increased, and splenic artery ligation partially lowered portal pressure. In three patients with varying cytopenias secondary to hypersplenism, splenic artery ligation uniformly improved peripheral blood elements, although varying degrees of hypersplenism later recurred necessitating splenectomy in one. Splenic artery ligation was performed in four of five other patients in conjunction with coronary vein ligation for bleeding esophageal varices. Two patients later required portacaval shunting and one other, in whom operation was undertaken in desperation, died of hepatic failure. Celiac-mesenteric arterioportography, operative portography, hemodynamic measurements, and examination of peripheral blood elements in these eight patients suggested that splenic artery ligation, in conjunction with coronary vein ligation, has several potentially beneficial effects. Each of these effects and their interrelations require further study before this operation assumes a larger role in the treatment of complications of portal hypertension.

3925 EFFECT OF PORTACAVAL SHUNT AND ACUTE HEPATIC ISCHEMIA ON BRAIN AND LIVER SEROTONIN AND CATECHOLAMINES. (Eng.) Reichle, R. M.; Reichle, F. A. (Temple Univ. Health Sciences Center, Philadelphia, PA). *Surg. Forum* 26:413-414; 1975.

Brain serotonin and dopamine levels were assayed 4 hr after acute hepatic ischemia (AHI) was induced in 40 male Sprague-Dawley rats; serotonin concentration was also determined in ischemic and nonischemic livers. Portacaval shunt (PCS) was performed in 40 rats by rapid cuff anastomosis. AHI was produced in 10 animals 24 hr after hepatic artery ligation and in 20 animals 21 days after PCS. AHI consistently produced tremors, progressive lethargy, and coma. Brain serotonin was significantly higher whether AHI was produced 24 hr after PCS (0.79 ± 0.03 μg/g in sham-operated controls and 1.19 ± 0.01 μg/g in AHI animals, $p<0.01$). By comparison, brain serotonin levels were not significantly changed compared to controls 21 days after PCS (without AHI). A slight increase in brain dopamine 3 weeks after PCS in AHI animals (1.24 ± 0.33 μg/g) over controls (0.98 ± 0.22 μg/g) was statistically insignificant. The hepatic serotonin concentration was significantly increased after AHI (19.4 ± 1.9 μg/g) over that in sham-operated controls (7.4 ± 0.6 μg/g); intrahepatic dopamine concentration was unchanged after AHI. Alterations in cerebral concentration of these compounds in AHI suggest an etiologic association between increased cerebral concentration of neurally active amines and the observed cerebral dysfunction that consistently occurs in this model of AHI.

3926 SPECIFIC ENDOCRINE AND HORMONAL RECEPTOR CHANGES ASSOCIATED WITH LIVER REGENERATION IN ADULT RATS. (Eng.) Leffert, H.; Alexander, N. M.; Faloona, G.; Rubalcava, B.; Unger, R. (Cell Biology Lab., Salk Inst., P.O. Box 1809, San Diego, CA 92112). *Proc. Natl. Acad. Sci. USA* 72(10):4033-4036; 1975.

Plasma levels of insulin, glucagon, and thyroxin were measured 0-24 hr after partial hepatectomy in male Fisher rats, and the capacity of plasma membranes derived from regenerating liver to bind peptide hormones was also measured. Within 3 hr after 70% hepatectomy, insulin levels fell, whereas glucagon levels rose; these changes were not observed in control rats that underwent laparotomy and liver manipulation. Thyroxin and glucose levels were also reduced, but reduction did not begin until 5 and 7 hr, resp., after partial hepatectomy. In separate experiments, the alterations in pancreatic hormone levels began 20 min after 70% hepatectomy (insulin 20 μU/ml at time 0 and 12 μU/ml after hepatectomy; glucagon 186 pg/ml at time 0 and 680 pg/ml after hepatectomy). Experiments with animals that received either 0, 10, 30, 50, or 70% hepatectomy showed that the plasma hormonal changes were proportional to the quantity of liver tissue excised. Plasma membrane preparations from 24-hr regenerating liver bound 40-60% less ^{125}I-labeled glucagon than preparations derived from sham or unoperated rats, whereas ^{125}I-labeled insulin binding was not detectably altered. Membrane-associated endogenous glucagon probably does not explain the diminished glucagon binding, because each group of membrane preparations contained equivalent trace amounts of endogenous immunoreactive glucagon (0.20-0.25 pg/mg protein). Hepatic plasma membrane preparations obtained 24 hr after laparotomy or after partial hepatectomy had similar amounts of 5'-nucleotidase activity (4.75 and 4.25 μmol 5'-AMP hydrolyzed/mg protein/hr, resp.), suggesting that a simi-

LIBRARY U.

lar plasma membrane fraction had been recovered under different experimental conditions. These experiments indicate that the liver participates in the regulation of circulating blood levels of hormones that are implicated in controlling hepatic proliferation and that liver regeneration induced by partial hepatectomy is accompanied by specific alterations at the level of the plasma membrane and/or hormonal membrane receptors.

3927 EFFECTS OF THE LIVER HOMOGENATE OBTAINED FOLLOWING PARTIAL HEPATECTOMY ON CIRRHOSIS OF THE LIVER.

(Eng.) Seres-Sturm, L.; Maros, T.; Lakatos, O.; Seres-Sturm, M.; Mody, E.; Blazsek, V. (Inst. Anatomy, Medical Univ., Str. Gh. Marinescu nr. 38, Tirgu-Mures, Rumania). *Exp. Pathol. (Jena)* 11(5/6):215-218; 1975.

The influence of liver homogenates on CCl_4-induced liver cirrhosis was investigated in male albino rats. The rats received 0.1-0.2 ml/100 g of a mixture containing CCl_4 plus Oleum Helianthi, i.m., twice weekly for 6 months. During the 6-week experimental period, all animals continued to receive CCl_4 once weekly. The histological and biochemical findings from 17 rats receiving CCl_4 and a normal lyophilized liver homogenate (10% isotonic solution of 3,500 x *g*/20 min supernatants; 0.2 ml/100 g, i.m., 3 times weekly) were similar to those from control animals after 6 months of treatment with CCl_4 alone. In 20 animals receiving CCl_4 and homogenate collected from rats 48 hr after partial hepatectomy, the cirrhotic changes were similar to both controls and animals receiving normal homogenate, but there was also a moderate hyperplasia of the parenchymal nodules and an increase in hepatocyte DNA concentration (cirrhotic controls=377.2 mg/100 g liver; rats receiving homogenate=523.2 mg/100 g). These results indicate that this liver homogenate stimulated the regeneration of the parenchymal cells. In 20 rats receiving CCl_4 and homogenate prepared from the residual liver at 7 days after partial hepatectomy, the lobular architecture was relatively well preserved. The connective tissue was much diminished, and only very slight dystrophic changes were present. There was a significant decrease in collagen (449 mg/100 g in cirrhotic control livers; 294.4 mg/100 g in livers of animals receiving homogenate) and an increase in liver DNA (443 mg/100 g). It appears that rat liver homogenate collected 7 days (postmitotic period) after partial hepatectomy causes the regression of lesions in advanced cirrhosis.

3928 STIMULATION OF ALBUMIN SYNTHESIS BY AMINO ACIDS FOLLOWING PARTIAL HEPATECTOMY IN THE RAT.

(Eng.) Kirsch, R. E.; Lloyd, E. A.; Frith, L. O.; Gordon, B.; Saunders, S. J. (Univ. Cape Town, Medical Res. Council Liver Res. Group, Cape Town 7900, South Africa). *Am. J. Clin. Nutr.* 28(12):1412-1415; 1975.

The role of amino acid supplementation on albumin synthesis following partial hepatectomy was studied in male Wistar rats. The amino acids were in the L-form and consisted of a mixture of arginine (19.30 mg), asparagine (14.40 mg), isoleucine (6.68 mg), leucine (12.91 mg), lysine (29.21 mg), methionine (5.17 mg), phenylalanine (7.75 mg), proline (31.63 mg), threonine (16.52 mg), tryptophan (3.99 mg), and valine (13.07 mg). Immediately following the completion of hepatectomy, some animals received the mixture dissolved in 2 ml of water via nasogastric tube over a period of 1-2 min; this was repeated the next day. When the results were expressed as mg/hr/300 g of rat, the albumin synthesis rates in the hepatectomized rats, with and without the amino acid mixture, was significantly lower than in sham-operated animals (4.89 and 7.03 mg/hr/300 g in partial hepatectomy and partial hepatectomy + amino acid animals, resp.; 10.18 and 9.28 mg/hr/300 g in sham-operated and sham + amino acid animals, resp.) Of the two groups of hepatectomized rats, those receiving amino acid supplements synthesized significantly more albumin. When the results were expressed differently, however, the partially hepatectomized rats and sham-operated rats had similar synthesis rates (3.07 and 3.43 mg/hr/g dry liver weight, resp.), while the hepatectomized rats receiving amino acids synthesized significantly greater amounts of albumin (4.31 mg/hr/g). The authors suggest that amino acid supplementation may enhance albumin synthesis via the release of hormones.

3929 AN INVESTIGATION OF THE HEPATOTOXICITY OF D-GALACTOSAMINE IN DIFFERENT SPECIES OF ANIMAL.

(Eng.) James, G. W. L.; Pickering, R. W.; Parker, F. L. (Dept. Pharmacology, Roussel Labs. Ltd., Swindon, Wiltshire, England). *Arzneim. Forsch.* 25(10):1593-1594; 1975.

The hepatotoxicity of d-galactosamine was investigated in male golden hamsters and T.O. mice. In the hamsters, i.p. doses of 200, 400, and 800 mg/kg of galactosamine resulted in increased SGOT (mean 92, 1894, and 4229 U/l, resp.) and SGPT (133, 2358, and 3420 U/l, resp.) levels within 48 hr, in comparison to controls (SGOT, 63 U/l; SGPT, 50 U/l). These increases were associated with liver cell damage in the two highest doses. Single doses of 400 and 800 mg/kg were more severely hepatotoxic when assessed at 48-72 hr than at 24 hr. The toxicity appeared to be maximum at 48-72 hr. The mice received one i.p. dose of 1,000, 1,250, or 1,500 mg/kg of galactosamine; two doses of 500, 600, or 750 mg/kg over a period of 48 hr; or three doses of 300, 400, or 500 mg/kg over 48 hr. Galactosamine at 1,250 mg/kg marginally increased serum transaminase levels when given as a single dose or when divided into two or three doses totaling 1,200 mg/kg; the SGOT levels were 482, 322, and 436 U/l for the single, double, and triple doses, resp. (control, 91 U/l), and the SGPT levels were 38, 59, and 237 U/l, resp. (control, 13 U/l). Doses of 1,500 mg/kg given as a single dose or divided into two doses gave a similar marginal increase in serum transaminase levels, but administration in three doses resulted in greater increases (SGOT, 1825 U/l; SGPT, 1134 U/l). From a plot of the dose of galactosamine versus the resulting increase in SGOT values in rats (previously reported), mice, and hamsters, the order of susceptibility is golden hamster > rat > mouse.

3930 NEWLY SYNTHESIZED HEPATIC CHOLESTEROL AS PRECURSOR FOR CHOLESTEROL AND BILE ACIDS IN RAT BILE.

(Eng.) Normann, P. T.; Norum, K. R. (Dept. Biochemistry, Inst. Nutrition Res., Univ. Oslo, Oslo, Norway). *Scand. J. Gastroenterol.* 11(4):427-432; 1976.

The origin of cholesterol and bile acids in the bile was studied using radioactively-labeled cholesterol and mevalonate. The two labeled compounds were added to serum, and 1 ml of this serum (containing 100 mCi DL-mevalonate-5-^{3}H and 2.3 mCi cholesterol-4-^{14}C) was injected into male Wistar rats anesthetized with sodium pentabarbitol. Bile was collected via a catheter at 15 min intervals. The specific activity (sp. ac.) of free and esterified cholesterol was calculated after determining the amounts of cholesterol by gas-liquid chromatography and radioactivity in a liquid scintillation spectrophotometer. The sp. ac. of bile acids was determined following liquid scintillation counting and enzymatic procedure. Bile cholesterol had the highest sp. ac. The sp. ac. of liver cholesterol was higher than that of serum cholesterol for the first 90 min, due probably to the liver's dominant role in cholesterol synthesis. The sp. ac. of chenodeoxycholic acid was higher than that of cholic acid, indicating higher incorporation of labeled compounds (ratio of 1:10). The decreasing ratio of ^{3}H/^{14}C labeled bile acids indicated that newly synthesized liver cholesterol was utilized preferentially as a precursor of bile acids. The same was true for bile cholesterol. The use of pentabarbitol (which lowers 12-α-hydroxylation) could have influenced the higher production of chenodeoxycholic acid relative to cholic acid. These findings are consistent with the assumption that unesterified cholesterol (and not esterified) is the immediate precursor for bile acids. The authors conclude that it is probably that the liver production of bile constituents is so organized that secreted products derive from an anabolic pool, and not from a catabolic pool.

3931 THE TOXICITY OF THIOXANTHENE NEUROLEPTICS TO ISOLATED RAT LIVER CELLS.

(Eng.) Aber-athy, C. O.; Zimmerman, H. J. (Liver Res. Unit, eterans Admin. Hosp., Washington, DC 20422). *Proc. oc. Exp. Biol. Med.* 150:385-389; 1975.

he hepatotoxicity of variously substituted thioxanhenes was compared to that of the structurally-imilar phenothiazine analogs using isolated liver ells. The cells were obtained from male CD rats. he drug solutions were added to the cell suspensions nd incubated at 37 C for 30 min. Samples of the edia were analyzed for the level of GOT; cell eakage of GOT was taken to be a measure of toxicity. ll the thioxanthenes examined caused leakage of OT, with the exception of N-710. The most potent as SKF10812, which caused leakage at 3 x 10^{-5} M. oth isomers of chlorprothixene and N-756A caused ignificant leakage at 6 x 10^{-5} M, while the two somers of flupenthixol caused leakage at 8 x 10^{-5} M. anthiol and methixene (also thioxanthenes) produced OT leakage at 9 x 10^{-5} and 2 x 10^{-4} M, resp. The somers of clopenthixol and N-716 caused leakage at x 10^{-4} M. Thioxanthenes with side chains attached by saturated C-C bonds produced less leakage than analogs with unsaturated C-C bonds, suggesting that the rigidity produced by the double bond may be of some importance in this phenomenon. The trifluoromethyl substituted thioxanthenes were three to four times more potent than their halogenated analogs. A dimethylaminopropylidene side chain was associated with five to six times as much GOT leakage as a side chain of hydroxyethylpiperazinylpropylidene. Some thioxanthenes were more potent than their phenothiazine analogs. Toxicity was not related to neuroleptic properties.

3932 INVESTIGATIONS ON THE PATHOGENESIS OF EXPERIMENTAL CHRONIC ACTIVE HEPATITIS (CAH) IN RABBITS.

(Ger.) Hopf, U.; Meyer zum Buschenfelde, K. H. (II. Med. Univ.-Klinik, D-6500 Mainz, Langenbeckstrasse 1, Germany). *Z. Gastroenterol.* 13(3):398-403; 1975.

The role of cellular and humoral immune reactions to human liver-specific protein (HLP) and allogeneic liver-specific protein (RLP) in the induction of hepatic lesions was studied in six groups of White New Zealand rabbits that received: (group 1) 41 injections (25 mg each) of HLP + complete Freund's adjuvant (CFA), i.p., over 143 weeks; (group 2) 26 injections (25 mg each) of HLP + CFA, i.p., over 18 weeks, followed by immunization with RLP + CFA as in group 1; (group 3) 26 injections (25 mg each) of HLP + CFA, i.p., alternated with the same dose of RLP, i.p., without CFA 1 day after the HLP injection; (group 4) 25 injections (5 mg each) of HLP + CFA, i.p., over 68 weeks; (5) HLP + CFA, i.p., as in group 4 alternated with 1-mg injections of RLP, i.v., 1 day before each HLP injection; and (group 6) controls given only CFA, i.p. Chronic active hepatitis (CAH) or cirrhosis and a positive skin reaction to RLP were found in all but one animal in group 1. Positive skin tests for RLP were obtained after 14 weeks in four of nine rabbits in group 2. All animals surviving 23 weeks had CAH. CAH was also found in two of eight rabbits in group 3; the skin test for RLP was still negative after 14 weeks in six of eight animals. The humoral immune reaction did not differ from that in groups 1 and 2. CAH was found in 7 of 11, and cirrhosis in 1 of 11 rabbits in group 4 after 70 weeks. The cellular immune reaction to RLP developed significantly later than in groups 1-3, and the antibody titer was significantly lower. CAH was found in 1 of 12 animals in group 5. Slightly positive cellular immune reaction to RLP was found in two animals. The RLP antibody titer did not differ appreciably from that in group 4. The findings indicate the possibility of CAH or cirrhosis induction in rabbits by long-term immunization with HLP, and that the autoimmunity to liver-specific antigens induced by HLP immunization can be maintained by allogeneic liver-specific proteins.

3933 THE EFFECT OF SILYMARIN-N-METHYLGLUCAMINE SALT AND SILYBIN-DIHEMISUCCINATE ON (1-^{14}C)-ACETATE INCORPORATION IN RAT LIVER LIPIDS.

3967 THE ASSOCIATION BETWEEN ACIDIFICATION AND ELECTROGENIC EVENTS IN THE RAT PROXIMAL JEJUNUM. (Eng.) Lucas, M. L. (Max-Planck Institut fur Biophysik, Kennedyallee 70, Frankfurt am Main, W. Germany). *J. Physiol. (Lond.)* 257(3):645-662; 1976.

Simultaneous measurement of hydrogen ion production, transmural potential difference, and intermittent short circuit current (SCC) was made in the rat proximal jejunum *in vitro*. Similarly, potassium and sodium ion movements were measured to investigate the relation of acidification to electrogenic events and associated ion movements in the jejunum. Acidification correlated significantly ($p<0.01$) with the short circuit current, and both were inhibited by 10 mM serosal ouabain or 10 mM mucosal aminophylline. Both inhibitors had effects on net potassium movement but not on net sodium movement. In isotope studies, 10 mM serosal ouabain reduced the J_{ms} sodium flux, and 10 mM mucosal aminophylline had no effect. Thus, aminophylline can reduce both SCC and acidification without perceptibly altering the serosally-directed sodium flux. There was some degree of correlation ($p<0.05$) between serosal potassium movement and acidification, but only when ouabain was present. Mucosal potassium ion movement correlated ($r=0.801$) moderately ($p<0.05$) with acidification, when compared over all experimental conditions, indicating the possibility of potassium hydrogen ion exchange. In the complete absence of the sodium ion, a reversed potential difference occurred, which was not sustained, but fell to zero after an initial peak. Serosal ouabain and mucosal aminophylline appeared to have precisely opposite effects. Ouabain caused an increase and aminophylline, a decrease, in the transient reversed potential differences. A model for acidification based on potassium is proposed to explain these findings.

3968 IN VITRO SYNTHESIS OF IMMUNOGLOBULINS, SECRETORY COMPONENT, COMPLEMENT AND LYSOZYME BY HUMAN GASTROINTESTINAL TISSUES. I. NORMAL TISSUES. (Eng.) Lai A Fat, R. F. M.; McClelland, D. B. L.; Van Furth, R. (Dept. Microbial Diseases, Univ. Leiden, Leiden, Netherlands). *Clin. Exp. Immunol.* 23(1):9-19; 1976.

The ability of human gastrointestinal tissue cultured *in vitro* to synthesize immunoglobulins (Ig) G, A, and M, secretory component (SC), complement proteins, and lysozyme was investigated. Histologically normal tissues were obtained endoscopically and surgically. IgA and SC were produced in all sites, but the relative intensity of IgA and SC synthesis varied. In stomach and small intestine, the intensity of IgA synthesis was greater than that of SC, but in large bowel mucosa, there appeared to be an excess of SC synthesis. Synthesis of IgG and IgM was also found in all sites. Complement proteins were produced by some of the intestinal biopsies, and by the parotid gland. Lysozyme was synthesized in the parotid gland and gastric mucosa and, to a lesser extent, in the small intestine; it was rarely synthesized in the large intestine. The results show that the synthesis of specific proteins can be detected in short term *in vitro* cultures of biopsies obtained from sites throughout the human gastrointestinal tract by standard methods.

3969 THE RELATIONSHIP BETWEEN PEPTIDE-HYDROLASE OF CYTOPLASM AND BRUSH BORDERS OF GUINEA-PIG SMALL-INTESTINAL MUCOSA. (Eng.) O'Cuinn, G.; Fottrell, P. F. (Dept. Biochemistry, Univ. Coll., Galway, Ireland). *Biochem. Soc. Trans.* 3(6):1219-1221; 1975.

Peptide hydrolases released from brush border of guinea pig small intestinal mucosa by sonication, Triton X-100, and papain were compared with cytoplasmic peptide hydrolases from the same tissue. Although six hydrolases have been previously observed in the mucosal cytoplasm, starch-gel electrophoresis of peptide hydrolases, released from brush borders by sonication or Triton X-100, reveale that only two hydrolases were present in this fraction. Their electrophoretic mobilities corresponded to those of the α and β peptide hydrolases of the cy plasm. Occasionally, a third peptide hydrolase was observed, corresponding to the "a" peptide hydrolase of cytoplasm. Similar results were obtained with l concentrations of papain (1 U/20 mg brush border pr tein), although qualitative differences between electrophoretic mobilities of peptide hydrolases of cytoplasm and of brush borders were obtained when higher concentrations of papain (100 U/20 mg) were used. In this case, a tripeptide hydrolase with an electrophoretic mobility corresponding to the β peptide hydrolase of cytoplasm was detected in addition to dipeptide hydrolases similar to the α and β peptide hydrolases of cytoplasm. The authors conclude that this unique tripeptide hydrolase is specifically brush border in location, and that this enzyme probably accounts for the significant proportion of tripeptide hydrolase activity previously detected in the brush border fraction of guinea pig small intestinal mucosa.

3970 PHOSPHOLIPID EXCHANGE PROTEINS IN RAT INTESTINE.

(Eng.) Lutton, C.; Zilversmit, D. B. (Laboratoire de Physiologie de la Nutrition, Faculte des Sciences d'Orsay 91 405, France). *Lipids* 11(1):16-20; 1976.

The existence of proteins that stimulate the exchange of phospholipids between cellular membranes in the intestine was investigated in male Sprague-Dawley rats. Homogenates of liver and intestine were centrifuged at 105,000 x *g* average to sediment cell debris and mitochondria and the pH was adjusted to 5.1. Exchange activity was determined by measuring the transfer of [^{32}P]phosphatidylcholine from liposomes (5 μg phospholipid P) to beef heart mitochondria. With 2, 4, and 8 mg of protein from liver or intestine (105,000 x *g* supernatant), 1.0, 2.0, 3.9 and 0.21, 0.43, 1.0 U, resp., of phosphatidylcholine exchange were found. Expressed per mg of protein in the 105,000 x *g* homogenate, the exchange activity of intestine was about one-fourth that of liver. The phosphatidylcholine exchange activity of the whole small intestine was estimated at 12-15% of whole liver. This active fraction showed the characteristics of a protein. Isoelectric focusing of the intestinal pH 5.1 fraction showed two peaks of phosphatidylcholine exchange activity: one at an acidic pH, the other in a basic pH range. The second peak of activity appeared to be a new phospholipid exchange. Phosphatidylcholine exchange activity was higher in mucosa than in the intestinal wall. No significant differences were found between villi and crypts or between jejunal and ileal villi. Exchange activity per mg of protein in mucosa was unaffected by fasting or by a high fat or high cholesterol diet. This suggests that phospholipid exchange activity in the absorptive cells is not a rate-limiting step in the process of fat absorption.

3971 STUDIES ON THE BRUSH BORDER MEMBRANE OF MOUSE DUODENUM. III. IODINATION OF MEMBRANE PROTEINS.

(Eng.) Billington, T.; Nayudu, P. R. V. (Dept. Zoology, Monash Univ., Clayton 3168, Victoria, Australia). *J. Membr. Biol.* 27(1/2):101-107; 1976.

To identify luminal surface proteins of the microvillus membrane of mouse duodenum, microvillus membranes were iodinated from luminally administered lactoperoxidase, H_2O_2, and ^{125}I before and after neuraminidase treatment. The membranes were isolated, solubilized in sodium dodecyl sulphate buffer, and electrophoresed on gels. The gels were stained for protein, and then sliced for liquid scintillation counting. When the membranes were not treated with neuraminidase, the nonpermeating iodination probe attached only to a band containing protein of 150,000 daltons (approximate molecular weight). This size class of protein may reside on the luminal side of the brush border membrane as opposed to the serosol side. Membranes treated from the luminal side with neuraminidase (to remove masking carbohydrate) and then iodinated, appeared to contain an additional protein of estimated molecular weight 220,000 daltons that was accessible to ^{125}I. A 220,000 dalton protein may also be on the luminal side of the membrane. Membranes were isolated, exposed to iodination, and then solubilized for electrophoresis. Nearly all proteins were labeled, which indicate that there is an asymmetric distribution of proteins in the plane of the membrane. The two smallest molecular weight polypeptides that were not iodinated are proposed to be so disposed in the membrane that they are inaccessible to the probe from either side.

3972 CHANGES OF TISSUE ACETYLCHOLINE IN THE DISTENDED INTESTINE.

(Eng.) Takewaki, T.; Yagasaki, O.; Yanagiya, I. (Faculty Agriculture, Univ. Gifu, Nakamonzen-cho, Kagamihara 504, Japan). *Jpn. J. Pharmacol.* 25(3):223-232; 1975.

The effects of distension of the intestinal wall on the liberation and synthesis of acetylcholine (ACh) were studied in isolated 4-cm segments of guinea pig ileum by measuring the changes in the amount of free and bound ACh. In the presence of 50 μM eserine, longitudinal distension did not increase the amount of free ACh in the intestinal wall, but did increase the amount of bound ACh from 9.7 μg/g to 11.8 μg/g. Circumferential distension or mucosal rubbing increased free ACh but not bound ACh. These effects occurred within 30 sec. In eserine-free medium, the amount of bound ACh was increased in either direction of distension (initially 5.8 μg/g, increased to 7.3 or 7.4 μg/g by longitudinal and circumferential distension, resp.). The addition of over 5×10^{-8} g/ml ACh to the bathing medium completely blocked the distension-induced increase. It is concluded that the release and synthesis of ACh may both be augmented by the circumferential and the longitudinal distension in the physiological conditions. In the presence of eserine, however, the presence of high extracellular ACh levels presumably inhibits the distension-induced augmentation of ACh synthesis in the tissue.

3973 RADIOIMMUNOASSAY STUDIES OF INTESTINAL CALCIUM-BINDING PROTEIN IN THE PIG. II. THE DISTRIBUTION OF INTESTINAL CaBP IN PIG TISSUES.

(Eng.) Arnold, B. M.; Kuttner, M.; Willis, D. M.; Hitchman, A. J. W.; Harrison, J. E.; Murray, T. M. (Dept. Medicine, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can. J. Physiol. Pharmacol.* 53(6):1135-1140; 1975.

The concentration of calcium-binding protein (CaBP) in the various tissues and organs of normal pigs was measured using a specific radioimmunoassay for porcine intestinal CaBP. Although most of the CaBP was present in the proximal small intestine, lower concentrations were found in other parts of the intestine; the amounts of CaBP decreased distally down the intestine in all six pigs. When duodenal, jejunal, and ileal extracts were assayed at several dilutions, the immunodilution curves were parallel to those seen for pure CaBP, indicating immunochemical similarity. Intestinal CaBP was also found, in lower concentrations, in kidney, liver, thyroid, pancreas, and blood. In all other tissues, including parathyroid, bone, skeletal muscle, and brain, CaBP immunoreactivity was undetectable or was less than in blood. The elution profile of CaBP activity and immunoreactivity from gel filtration analysis of kidney and parathyroid extracts suggests that the CaBP in the parathyroid gland and the major CaBP in the kidney are chemically and immunochemically different from intestinal CaBP.

3974 RADIOIMMUNOASSAY STUDIES OF INTESTINAL CALCIUM-BINDING PROTEIN IN THE PIG. I. IDENTIFICATION OF INTESTINAL CALCIUM-BINDING PROTEIN IN BLOOD AND RESPONSE TO A LOW CALCIUM DIET. (Eng.) Arnold, B. M.; Kuttner, M.; Swaminathan, R.; Care, A. D.; Hitchman, A. J. W.; Harrison, J. E.; Murray, T. M. (Univ. Toronto, Dept. Medicine, Toronto, Ontario M5S 1A8, Canada). *Can. J. Physiol. Pharmacol.* 53(6):1129-1134; 1975.

The change in the blood calcium-binding protein (CaBP) concentration after adaption to a low Ca diet was investigated in pigs and correlated with changes in intestinal CaBP concentration. Two of four 15-week-old littermate pigs were placed on a low Ca diet (0.15% Ca, 0.65% P), and two were placed on a control diet (0.65% Ca, 0.65% P). After 2 weeks, the entire small intestine was removed and divided into nine 1.8-m segments. The CaBP was assayed in both plasma and intestinal mucosa. The CaBP concentration in unextracted mixed venous plasma from 14 healthy pigs ranged from 28 to 90 ng/ml, which was lower than the concentration in the duodenum by a factor of 10^{-5}. There was an increase in immunoreactive CaBP in both plasma and intestinal mucosa in pigs on a low Ca diet, as compared to controls. There was no increment in immunoreactive CaBP in the first 1.8-m segment of small intestine. A total of 71% of the increment in CaBP occurred distal to the first two segments. The largest fractional increase (over 30 fold) was in the sixth segment, where the concentration increased from 5.5 to 184 μg/g. The mean CaBP concentration for the total small intestine increased by a factor of 1.9, while the plasma CaBP concentration increased by a factor of 2.6. Plasma CaBP was a more reliable indicator of change in CaBP status than was the measurement in the proximal gut segment, which contained the duodenum. It is concluded that the assay of CaBP in blood is convenient and may obviate the sampling errors inherent in intestinal biopsy.

3975 SUBCELLULAR LOCALIZATION OF DIPEPTIDES IN THE SMALL INTESTINE OF ANIMALS. (Rus.) Smirnova, L. F.; Timofeeva, N. M.; Ugolev, A. M. (I. P. Pavlov Inst. Physiology, USSR Acad. Sciences, Leningrad, USSR). *Dokl. Akad. Nauk SSSR* 228(4):992-994; 1976.

GENERAL

3976 THE NEURAL CREST AND THE ORIGIN OF THE INSULIN-PRODUCING AND OTHER GASTROINTESTINAL HORMONE-PRODUCING CELLS. (Eng.) Pictet, R. L.; Rall, L. B.; Phelps, P.; Rutter, W. J. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA 94143). *Science* 191(4223):191-192; 1976.

To test the hypothesis that the endocrine cells of the digestive tract derive from the neuroectoderm (neural crest), the entire ectoderm was removed from whole 9-day rat embryos prior to four somites. After the remaining mesoendoderm was cultured for 11 days in Eagle's basal medium (containing 10% embryo extract, 10% mesenchymal factor, and six times the usual amount of amino acid), insulin and B cells in approximately normal proportions were found in every culture in which a pancreas developed (approximately one-fourth of the cases). When mesoendoderm explanted at three somites or less were cultured, the amount of insulin found in the differentiated pancreas was between 0.5 and 2 ng (corresponding to ≈50-200 B cells/pancreas), approximating the normal proportion of insulin and B cells expected at this stage. It is concluded that the endocrine B cells are not derived from the neural crest.

3977 INTESTINAL ATRESIA IN FETAL DOGS PRODUCED BY LOCALIZED LIGATION OF MESENTERIC VESSEL (Eng.) Koga, Y.; Hayashida, Y.; Ikeda, K.; Inokuchi

K.; Hashimoto, N. (Kyushu Univ. Sch. Medicine, Fukuoka City, Fukuoka Prefecture, Japan). *J. Pediatr. Surg.* 10(6):949-953; 1975.

The process of intestinal infarct was investigated histopathologically in 13, 45- to 55-day-old dog fetuses. Ileal atresia and stenosis were produced by a localized ligation of the mesenteric vessels. The intestinal infarct resulted in an aseptic coagulation necrosis that was selectively limited to the mucosa and submucosa. The inflammatory cell reaction in the noninfarcted tissue adjacent to the affected segment was negligible, although hyperemia and capillary dilatation were intense. By the fifth postoperative day, the necrotic mass was replaced by ingrowing granulation tissue. Thereafter, proliferation and consequent contraction of the granulation tissue ensued, leading to the obstruction of the intestinal lumen. Type 2 atresia, in which there was a long cord segment between the blind ends of the intestine, was seen 11 days after devascularization. Because the microscopic findings of the atretic segment were similar to those described in humans, the course of intestinal atresias in humans may be similar and may be caused by vascular occlusive phenomena.

3978 SPHERICAL AGGREGATES OF COXSACKIE B_4 VIRUS PARTICLES IN MOUSE PANCREAS. (Eng.)

Harb, J. M.; Burch, G. E. (Tulane Univ. Dept. Medicine, 1430 Tulane Ave., New Orleans, LA 70112). *Beitr. Pathol.* 156(2):122-127; 1975.

A high titer culture of Coxsackie B_4 virus was used to induce pancreatitis in newborn HaM/ICR mice. One or two days after the i.p. inoculation of 0.1 ml of virus culture fluid ($10^{-8.5}$ $TCID_{50}$), cytonecrosis consistent with picornaviral infection, as well as necrosis indicative of pancreatitis, was observed. Aggregates of particles resembling Coxsackie B_4 virus particles, some arranged in the typical picornaviral crystalloid lattice formation and others arranged into spherical masses approximately 102 nm in diameter, were also seen. Depending upon the depth and orientation of section through the spherical aggregates, the particles were arranged into two readily distinguishable patterns. When the plane of section was through the center of the sphere, 10 particles, circularly arranged around a dense particle core, were observed; when the sphere was cut tangentially, the particles were arranged in a zig-zag pattern so that there were two concentric layers of at least 6 particles per layer and no central core. Both crystalloid and spherical aggregates were observed to be free within acinocyte cytoplasm, and within autophagic vacuoles, cytosegresomes, and fine granular bodies of acinocytes, and within phagocytic vacuoles of macrophages. It is concluded that the spherical aggregates represent a distinct crystalloid form of Coxsackie B_4 virus during its replicative cycle, which may eventually develop into the more typical picornaviral crystalloid lattice configuration and that the spherical aggregates are located in foci of viral synthesis.

3979 EFFECT OF CIMETIDINE ON GASTRIC POTENTIAL DIFFERENCE IN MAN. (Eng.)

Ivey, K. J.; Baskin, W.; Jeffrey, G. (Sch. Medicine, Univ. Missouri, Columbia, MO 65201). *Lancet* 2(7944):1072-1073; 1975.

In order to evaluate cimetidine-induced changes on the mucosal barrier, its effect on the gastric potential difference (PD) was studied in five healthy subjects. The PD was recorded continuously, and basal PD (mean ± standard error) was -48 ± 1.0 mV. Cimetidine (300 mg, p.o.) increased the PD to -64 ± 2.4 mV ($p<0.001$). Cimetidine also significantly decreased basal acidity from pH 2 to pH 7 within 1 hr. The effect on both the PD and pH persisted throughout each 3-hr study. The PD is known to correlate with changes in the human gastric mucosal barrier. Cimetidine may have a protective effect on the gastric mucosal barrier in addition to its suppression of acid secretion, and may, therefore, be of value in treating patients with gastric ulcer who may have an abnormal gastric mucosal barrier.

3980 HYPERTROPHY AND HYPERPLASIA OF THE NEONATAL RAT EXOCRINE PANCREAS INDUCED BY ORALLY ADMINISTERED SOYBEAN TRYPSIN INHIBITOR. (Eng.)

Melmed, R. N.; El-Aaser, A. A. A.; Holt, S. J. (Hadassah-Univ. Hosp., P.O. Box 499, Jerusalem, Israel). *Biochim. Biophys. Acta* 421(2):280-288; 1976.

RNA, DNA, protein, and phospholipid synthesis were measured in the neonatal Wistar rat pancreas following the daily p.o. administration of partially purified soybean trypsin inhibitor (2 mg/g). Studies involving the i.p. injection of ^{3}H-thymidine, ^{13}C-orotic acid, ^{3}H-leucine, or ^{14}C-glycerol showed an enhanced synthesis of DNA, RNA, protein, and phospholipid, resp. Evidence of true hyperplasia, in addition to this cellular hypertrophy, was provided by an increased mitotic activity in the exocrine pancreas following a wave of enhanced ^{3}H-thymidine incorporation into DNA. Complete inhibition of the stimulated RNA synthesis by low doses of actinomycin D (80 μg/kg, i.p.) indicated the importance of transcription as a regulatory step in the response of the exocrine pancreas to trophic stimulation by this means. Collateral observations of ^{3}H-thymidine and ^{14}C-orotic acid incorporation into liver DNA and RNA, resp., failed to demonstrate comparable changes, confirming the probable specificity of the trypsin inhibitor-induced effect on the exocrine pancreas. It is suggested that the pronounced trophic effect of p.o. administered soybean trypsin inhibitor in the neonatal rat pancreas may serve as a useful model for the study of regulatory mechanisms of nucleic acid and protein synthesis in the mammalian pancreas.

3981 SECRETIN CELLS IN THE GASTROINTESTINAL TRACT. (Eng.)

Chey, W. Y.; Escoffery, R. (224 Alexander St., Rochester, NY 14607). *Endocrinology* 98(6):1390-1395; 1976.

The morphology and distribution of secretin (S) cells in the gastrointestinal tract were investigated by the indirect immunofluorescence antibody technique, using a highly specific rabbit anti-secretin sera in nine human subjects and in five mongrel dogs. The fluorescence reaction was not blocked by an excess amount of gastrin, cholecystokinin, glucagon, vasoactive intestinal polypeptide, or motilin, whereas secretin blocked the reaction. The S cells were seen in the mucosa of the antrum and duodenum in both humans and dogs and throughout the entire length of the canine small intestine. They were not found in the mucosa of the esophagus, fundus of the stomach, or rectum. These cells were either pyramidal in shape or pear shaped and were one third of the size of gastrin cells. A small number of S cells were seen in the body of the stomach in two human subjects, but they were absent in the mucosa of the esophagus and the rectum. The results indicate that S cells are distributed throughout the entire length of the small intestine including the duodenal bulb, although they were seen more frequently in the duodenum, as observed in other studies.

3982 PHARMACOLOGIC STUDIES OF HIRSCHSPRUNG'S DISEASE ON A MURINE MODEL. (Eng.) Richardson, J. (McGill Univ., 3655 Drummond St., Montreal, P.Q., Canada H3G 1Y6). *J. Pediatr. Surg.* 10(6):875-884; 1975.

The pharmacology of a murine model of aganglionosis was investigated in C57Bl-a$^+$ mice to demonstrate the presence or absence of the nonadrenergic inhibitory system in the aganglionic contracted portion of the terminal bowel. The contracted portion of the terminal colon and rectum of 44 affected mice was removed and mounted longitudinally in a 10 ml bath to which rectangular pulses of 50-70 V (0.5 msec duration) and 2-20 Hz were delivered. Drugs were added to the bath. The diseased bowel showed slow (2/min) regular contractions of high amplitude, while the normal bowel showed rapid (10-12/min) regular contractions of low amplitude. Epinephrine (10^{-6}-10^{-7} g/ml), norepinephrine, and isoproterenol abolished the large contractions of the abnormal bowel and relaxed it. Acetylcholine (10^{-8}, 10^{-7}, 2 x 10^{-7} g/ml) contracted both the normal and abnormal bowels. Atropine (10^{-7} g/ml) decreased the amplitude of the contractions of the abnormal bowel, but did not completely abolish them. Field stimulation produced a relaxation and rebound contraction in the normal bowel, but not in the diseased bowel. Bretylium tosylate (10^{-5} g/ml), propranolol (10^{-6} g/ml), hexamethonium, phenoxybenzamine hydrochloride (10^{-6} g/ml), and indomethacin (20, 100 μg/ml) had no effect on the relaxation of the normal tissue in response to field stimulation, in the presence of adrenergic and cholinergic blockage. Tetrodotoxin (2 x 10^{-7} g/ml) abolished the relaxation on the subsequent contraction produced by field stimulation. Dopamine had no obvious effect on either the normal or the abnormal tissues. ATP (10^{-5} M) did not produce a relaxation of either the normal or the abnormal bowels. The results indicate an absence of, or a defect in, the nonadrenergic inhibitory nervous system in the spastic bowel of the diseased mice and confirm previous findings in human tissue.

3983 CONJUGATIVE BIOTRANSFORMATION OF XENOBIOTICS IN THE GUNN RAT [Abstract]. (Eng.) Marniemi, J.; Vainio, H.; Parkki, M. G. (Dept. Physiology, Univ. Turku, 20520 Turku 52, Finland). *Acta Physiol. Scand.* 95(2):61A-62A; 1975.

DIAGNOSTIC PROCEDURES

3996 DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE BY QUANTITATIVE BIOCHEMICAL ASSAY OF ACETYLCHOLINESTERASE IN RECTAL TISSUE. (Eng.) Boston, V. E.; Dale, G.; Riley, K. W. A. (Fleming Memorial Hosp. Sick Children, Great North Road, Newcastle-upon-Tyne, NE2 3AX, U.K.). *Lancet* 2(7942):951-953; 1975.

Acetylcholinesterase activity was measured in rectal biopsy specimens from 19 children in whom a provisional diagnosis of Hirschsprung's disease had been made. The biochemical assay was based on the procedure in which thiocholine, produced by enzymic hydrolysis of acetylthiocholine iodide, reacts with a color reagent to produce an anion with a peak absorbance at 412 nm. Seven children, in whom histological examination of biopsy material confirmed the diagnosis, had a mean acetylcholinesterase activity of 10.5 U/g tissue (standard deviation=6.9), while the remaining 12 children, in whom the diagnosis was excluded, had a mean activity of 34.34 U/g (s.d.=18.08). The difference between the two groups was statistically significant ($p<0.001$). The results indicate that the measurement of acetylcholinesterase activity may be valuable in the diagnosis of Hirschsprung's disease.

3997 ELECTROPHORETIC AMYLASE FRACTIONATION AS AN AID IN DIAGNOSIS OF PANCREATIC DISEASE. (Eng.) Legaz, M. E.; Kenny, M. A. (Univ. Washington Sch. Medicine, Seattle, WA 98195). *Clin. Chem.* 22(1):57-62; 1976.

Six α-amylase isoenzymes were resolved by electrophoresis on cellulose acetate membranes in a discontinuous buffer system. The fastest migrating isoenzymes were of salivary origin (S1, S2, and S3); the slower ones were of pancreatic origin (P1, P2, and P3). The amylase isoenzyme distribution was determined in the sera of 240 subjects. A specific pancreatic isoenzyme (P3) was observed in all clinically diagnosed cases of acute or chronic pancreatitis and in 15 of 40 renal-transplant patients. P3 isoenzyme activity declined during apparent recovery from pancreatitis. The P2 isoenzyme appeared in 95% of all specimens, P1 in only 2%. The pancreatic isoenzymes were preferentially excreted in the urine of both renal transplant patients and normal individuals. The major salivary isoenzyme, S1, was observed in 95% of all serum and urine samples; S2 and S3 appeared less consistently. The method is simple and rapid, and is applicable for use in the clinical evaluation of patients with pancreatitis or with nonpancreatic dysfunction.

3998 INCIDENCE AND CLINICAL SIGNIFICANCE OF e ANTIGEN AND ANTIBODY IN ACUTE AND CHRONIC LIVER DISEASE. (Eng.) Eleftheriou, N.; Heathcote, J.; Thomas, H. C.; Sherlock, S. (Royal Free Hosp., London NW3, England). *Lancet* 2(7946):1171-1173; 1975.

The sera of a variety of patients with liver disease, including asymptomatic hepatitis B surface antigen (HBsAg) carriers, were tested for the presence of e antigen and its antibody (anti-e) by a standard immunodiffusion technique, and the clinical value of the e/anti-e system was evaluated. The antigen was not detected in the serum of any of 99 cases of acute type B hepatitis who recovered normally. Anti-e was found in 14 cases. The antibody usually appeared before the clearance of HBsAg and before th appearance of antibody to HBsAg (HBsAb). Serum e wa not detected in any of 29 asymptomatic carriers of HBsAg, but 21 showed anti-e. Serum e was found in the sera of 35 of 79 patients with chronic active hepatitis and in the sera of 5 of 16 patients with chronic persistent hepatitis. The antibody was detected in only 2 of 79 patients with chronic activ hepatitis but in 7 of the 16 patients with chronic persistent hepatitis. Serum e was not found in five patients with primary liver cell carcinoma or in five with inactive HBsAg-positive cirrhosis. The antibody was found in all five of those with inactiv cirrhosis and in four of the five with primary cance These results suggest that the presence of e antigen is associated with active, and usually continuing, liver disease. Anti-e, however, is associated with inactive liver disease and asymptomatic carriage of HBsAg, and its presence is a valuable sign in predicting those who will escape progressive chronic liver disease.

3999 SERUM LYSOZYME IN INFLAMMATORY BOWEL DISEASE. (Eng.) Dronfield, M. W.; Langman, M. J. S. (City Hosp., Nottingham, U.K.). *Gut* 16(12):985-987; 1975.

The mean serum concentration of lysozyme was determined by spectrophotometry and by a lysoplate method and compared in 27 patients with Crohn's disease, 25 patients with ulcerative colitis, and 26 healthy volunteers. The mean concentration was significantl higher in patients with Crohn's disease and ulcerative colitis than in the controls ($p<0.001$ and $p<0.02$, resp.). Higher levels than those found in any of the controls were obtained in 11 patients with Crohn's disease and in 6 with ulcerative colitis. The mean lysozyme concentration in Crohn's disease was not significantly higher than that in ulcerative colitis. It seems likely that the raised enzyme levels detectable in some patients wer due to lysozyme derived from tissue macrophages and epithelioid cells, as no correlation was detectable between serum lysozyme and blood monocyte or neutrophil counts. These findings differ from those obtained by previous authors, who suggested that serum lysozyme levels would be useful in distinguishing Crohn's disease from ulcerative colitis.

4000 BARIUM-ENEMA STUDY FINDINGS IN ASYMPTOMATI PATIENTS WITH RECTAL POLYPS. (Eng.) Cor-man, M. L.; Veidenheimer, M. C.; Coller, J. A. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Lahey Clin. Found. Bull.* 24(4) 133-159; 1975.

The value of barium enema on patients found to have asymptomatic rectal polyps was investigated in 200 consecutive patients. In all, 311 polyps were found: 153 patients had a single rectal polyp (76.5%), 26 patients had two polyps (13.0%), five had three polyps (2.5%), and 16 patients had four or more polyps. The polyps were evenly distribute

LIBRARY U.

around the circumference of the bowel. The sizes of the polyps found on proctosigmoidoscopy were estimated, the largest was 35 mm in diameter and the mean size was 5.5 mm. Sessile polyps were found in 176 patients (88%) and pedunculated polyps in 24 patients (12%). In 177 patients (88.5%), barium enema studies disclosed no abnormality except insignificant diverticular disease. Questionable filling defects in 18 patients (9%) necessitated repeat air-contrast barium enema studies. In each of these cases, the repeat study failed to confirm the presence of the polyp. In four patients (2%, case reports included), barium enema studies disclosed unquestionable polypoid lesions. In one patient a carcinoma of the sigmoid colon was demonstrated and confirmed on repeat examination. The 200 patients had a total of 219 barium enema studies, but the overall incidence of significant pathologic findings was 2.5%. Routine use of barium enema studies for patients with sessile polyps cannot be supported in terms of cost on the basis of this report.

4001 IMPORTANCE OF THE SITE OF ENDOSCOPIC GASTRIC BIOPSY IN ULCERATING LESIONS OF THE STOMACH. (Eng.) Hatfield, A. R. W.; Slavin, .; Segal, A. W.; Levi, A. J. (Northwick Park Hosp., Watford Rd., Harrow, Middlesex HA1 3UJ, U.K.). *Gut* 16(11):884-886; 1975.

To determine the best site for gastric biopsy, 20 freshly resected stomach specimens, each containing an ulcerated carcinoma, were studied. Using endoscopic biopsy forceps, multiple biopsies were obtained from various sites around the ulcer. Carcinoma was detected with similar frequency in biopsies from the slough (75%) and from the rim (80%) of the ulcer. The positive biopsy rate was increased to 95% when the results from the rim and the slough were combined. The authors suggest that the diagnostic accuracy of endoscopic gastric biopsy can be improved by taking biopsies from both the rim and the slough of an ulcer.

4002 COLONOSCOPY ASSOCIATED BACTEREMIA. (Eng.) Dickman, M. D.; Farrell, R.; Higgs, R. H.; Wright, L. E.; Humphries, T. J.; Wojcik, J. D.; Chappelka, R. (Naval Regional Medical Center, Philadelphia, PA). *Surg. Gynecol. Obstet.* 142(2):173-176; 1976.

The incidence of bacteremia was investigated before and after diagnostic and/or therapeutic colonoscopy in 52 patients. Of the 27 patients who underwent diagnostic colonoscopy, 2 were found to have procedure-associated isolates. Both patients had colonic carcinoma involving the liver. *Escherichia coli* and bacteriodes species were found in blood samples taken at 5 min after the procedure in the first patient and at the time the colonoscope was in the transverse colon of the second patient. Bacteroides bacteremia was also found in a third patient in whom inadvertent perforation of the colon occurred. Bacteremia was not found in any of 13 patients who underwent both colonoscopy and biopsy or in 12 patients who underwent both colonoscopy and snare polypectomy. Of the four patients with disorders potentially impairing host defences, only the two mentioned above developed bacteremia. These data suggest that routine prophylactic antibiotic coverage is unnecessary in uncompromised patients.

4003 ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP) IN PATIENTS WITH BILLROTH II PARTIAL GASTRECTOMIES. (Eng.) Osnes, M.; Myren, J. (Ulleval Hosp., Oslo 1, Norway). *Endoscopy* 7(4):227-232; 1975.

A new technique to facilitate entering the afferent loop with the duodenoscope in endoscopic retrograde cholangiopancreatography (ERCP) was used on 20 patients who had had Billroth II partial gastrectomies. A graded stiffening of the duodenoscope (Olympus JF B 2) was performed by hand after introduction of the tube into the channel of the duodenoscope. The tube was not removed until the duodenoscope had entered the descending part of the duodenum and was localized for the cannulation of the papilla of Vater for ERCP or for the inspection of the sutured duodenal stump. Entering of the afferent loop with visualization of the papilla of Vater was successful in 17 patients, and cannulation of the papilla was achieved in 16 cases. A retrograde cholangiography was obtained in 14 patients. Retrograde pancreatography was obtained in 13 cases. No complications occurred. This method apparently results in a higher rate of successful ERCP procedures than reported by previous authors.

4004 PSEUDOCALCULUS OF THE COMMON BILE DUCT: A DYNAMIC RADIOGRAPHIC DIFFERENTIATION FROM TRUE RETAINED STONE. (Eng.) Wertheimer, M.; Brooke, W. S.; Koehler, P. R.; Nelson, J. A. (Univ. Utah Medical Center, Salt Lake City, UT). *Am. J. Surg.* 130(6):742-745; 1975.

The radiographic differentiation of pseudocalculus of the common bile duct from a true retained stone is discussed. In the past 4 yr, five patients with static T-tube cholangiographic evidence of retained distal common duct calculi have been seen. A preoperative cholangiogram demonstrated these to be pseudocalculi, or artifacts of common bile duct physiology and anatomy. The unique anatomy and physiology of the distal common duct are responsible for the production of the pseudocalculus sign. During maximal sphincter contraction, contrast material in the common bile duct may demonstrate a convexity or a meniscus identical to that which might be produced by a true calculus. This is the pseudocalculus sign, and static cholangiograms illustrating this sign are presented. The risk of mortality and morbidity with reexploration of the common duct emphasizes the need for differentiating a pseudocalculus from a true retained stone.

4005 PERCUTANEOUS ANTECUBITAL TRANSVENOUS CHOLANGIOGRAPHY: A MODIFIED TECHNIQUE USING A FLEXIBLE NEEDLE. (Eng.) Hawkins, I. F., Jr.; NcNeely, G. F.; Weaver, D. L., Jr. (Univ. Florida Coll. Medicine, Gainesville, FL 32610). *Radiology* 120(2):423-425; 1976.

LIBRARY U.

A modified technique of percutaneous antecubital transvenous cholangiography that facilitates the procedure in patients with fibrotic livers is described. A number 9 French catheter is positioned in the right hepatic vein with a flexible 20-gauge needle extending into the liver parenchyma. The number 9 French catheter is inserted over a number 5 French teflon catheter-guide wire combination. The needle is sheathed in a number 5 French catheter inside a number 9 French catheter, and its tip is positioned just proximally to the end of the sheath. The number 5 French sheath and number 9 French catheter are stabilized, and the hub of the needle is advanced under fluoroscopic control. The position of the tip can be verified externally by a mark at the hub end of the needle. In children, a 20- or 21-gauge cannula with a pencil-point stylus is employed instead of a number 5 French Teflon sheath, and a number 5 French Teflon catheter is used in place of the number 9 French catheter. The percutaneous antecubital transvenous cholangiography was used in eight patients, and was successful in the six patients with obstructive jaundice; the failures occurred in two patients with no bile duct dilatation. There were no complications, and no bile leakage or bleeding was seen at laparotomy. This technique appears to be the method of choice, as it is fast (less than 30 min in each of the 8 patients), requires very little skill to catheterize the hepatic veins, and because multiple passes into the parenchyma can be easily accomplished.

4006 A SIMPLE TEST TO DETERMINE THE SITE OF BLEEDING IN THE UPPER PART OF THE GASTROINTESTINAL TRACT. (Eng.) Rosenberg, S. A.; Harken, A. H. (Peter Bent Brigham Hosp., Boston, MA). *Surg. Gynecol. Obstet.* 142(2):241-242; 1976.

A noninvasive test for distinguishing variceal bleeding from bleeding due to gastritis or ulcer disease was tested in 14 patients with upper gastrointestinal bleeding. The test was based upon certain principles: blood from esophageal varices contains highly unsaturated hemoglobin; arterial blood from gastritis and ulcer disease is well oxygenated; and small amounts of unsaturated venous blood are capable of binding the small volume of oxygen dissolved in saline solution irrigant, significantly lowering the oxygen tension of the mixture. Thus, 100 ml of saline were instilled into the stomach of the bleeding patient, and arterial and venous blood samples were obtained. Blood tinged gastric saline solution were then obtained in 5-ml samples, and oxygen tension and hemoglobin concentration were measured. The test correctly predicted the site of bleeding in four of five patients with variceal hemorrhage and in all nine patients with bleeding from gastritis or ulcers. Preliminary results suggest further use and evaluation of the test.

4007 MASSIVE EXTRA-ENTERIC GASTROINTESTINAL BLEEDING: ANGIOGRAPHIC DIAGNOSIS. (Eng.) Koehler, P. R.; Nelson, J. A.; Berenson, M. M. (Univ. Utah Medical Center, 50 N. Medical Drive, Salt Lake City, UT 84132). *Radiology* 119(1):41-44; 1976.

Two patients with life-threatening gastrointestinal bleeding arising from aneurysms in visceral vessels outside the alimentary tract are described. The first patient, a 51-yr-old woman with a history of chronic calcific pancreatitis and mild hypertension, had intermittent episodes of right upper quadrant and epigastric pain associated with hematemesis and melena, slight scleral icterus, and mild hepatomegaly. Celiac angiography revealed a small aneurysm in the branch of the left hepatic artery. At laparotomy, the common duct was found to be greatly dilated. Operative cholangiography revealed multiple radiolucent filling defects in the biliary tract; the bile ducts were opened, multiple blood clots were extracted, the common hepatic artery was ligated, and the patient has remained asymptomatic for 3 yr since surgery. The second patient, a 60-yr-old woman, experienced anemia, malaise, melena, acute rectal bleeding, and hematemesis. Celiac and superior mesenteric angiography were initially interpreted as normal, except for a small aneurysm at the distal end of the splenic artery. The presumptive diagnosis of bleeding cecal diverticulum was made; subtotal colectomy was performed and the patient remained asymptomatic for 3 months. When gastrointestinal bleeding recurred, a visceral angiogram demonstrated that the splenic artery aneurysm ha increased in size. Re-injection of the celiac arter demonstrated that the aneurysm had continued to increase in size, and during one injection, extravasation of contrast medium into the main pancreatic duct was observed. On histological examination of the sections taken through the pancreas, a markedly dilated pancreatic duct was found with portions of the duct occluded by fresh thrombus. Verhoeff van Gieson stain revealed a region of aneurysmal dilatation of the branch of the splenic artery with direc communication between it and the lumen of the pancreatic duct. Endoscopy and/or barium contrast studies were of little value in the diagnosis of the aneurysms in these patients, and the conclusive diagnosis was made by angiography. It is concluded that splenic artery aneurysms should usually be resected and splenectomy should be performed; hepati artery aneurysms are probably best treated by segmental hepatic resection, but hepatic artery ligations, proximal to the gastroduodenal artery, may also prove successful.

4008 GALLIUM CITRATE Ga 67 ACCUMULATION IN PSEUDOMEMBRANOUS COLITIS. (Eng.) Tedesco F. J.; Coleman, E.; Siegel, B. A. (Univ. Miami Sch. Medicine, PO Box 520875, Biscayne Annex, Miami, FL 33152). *JAMA* 235(1):59-60; 1976.

The case of a 71-yr-old man with a colonic accumulation of ^{67}Ga in conjunction with pseudomembranous colitis is presented. The patient underwent laparotomy, which revealed obstruction of the distal ileum by adhesive bands and perforation of a jejunal diverticulum with an omental abscess; 60 cm of the small bowel was resected, and the adhesive bands wer lysed. On the 17th postoperative day, a ^{67}Ga-scan was performed to evaluate a possible intra-abdominal abscess; the images at both 48 and 68 hr showed diffuse activity within the entire colon. On the 24th postoperative day, proctoscopy showed 5-mm plaqueike lesions covering the rectal mucosa; a rectal iopsy confirmed the diagnosis of pseudomembranous olitis. Blood and tissue samples were obtained at bout 97 hr after the injection of a radiopharmaeutical and were counted in a crystal-well scinillation counter. The tissue/serum activity ratio as 45.3 for the pseudomembrane, 57.5 for the adjaent colonic mucosa, and 0.2 for the luminal contents. n this patient, colonic accumulation of ^{67}Ga was not ue to luminal activity but to concentration in the nflamed mucosa and pseudomembranes. This was conirmed by counting the biopsy specimens. The findings ndicate that apparent colonic activity on ^{67}Gamages should not always be assumed to represent ecal activity. The possibility of colonic wall ocalization in inflamed bowel should be considered.

009 CHRONIC GASTRITIS--A SIMPLE CLASSIFICATION.

(Eng.) Rao, S. S.; Krasner, N.; Thomson, . J. (Stobhill General Hosp., Glasgow, G21 3UW, cotland). *J. Pathol.* 117(2):93-102; 1975.

simple classification of chronic gastritis, based n subjective assessment of the degree of chronic nflammatory infiltration and atrophy of mucosal lands, was employed with gastric biopsy specimens rom 241 patients with chronic peptic ulceration, astric carcinoma, or x-ray-negative dyspepsia. he biopsies were taken from the mucosa of the pyoric antrum and from the lower, middle, and upper hirds of the stomach. Chronic inflammatory cellular nfiltration confirmed the diagnosis of chronic astritis in 184 patients. Of 28 patients with a ild degree of chronic inflammatory cell infiltration mainly of plasma cells and lymphocytes), 5 showed trophy. Of 88 patients with moderately severe hronic inflammatory cell infiltration (lymphocytes, lasma cells, and a few eosinophils), atrophy was resent in 23. Of the 68 patients with severe hronic inflammatory cell infiltration (lymphocytes, lasma cells, eosinophils, and a few neutrophil olymorphs), 39 demonstrated loss of glands and trophy. True superficial gastritis was seen in nly three patients; the chronic inflammatory cell nfiltration was limited to the lamina propria etween gastric pits in these patients. The authors onclude that many cases of superficial gastritis re really mild, moderately severe, or severe cases f chronic gastritis without atrophy, and that their lassification can be applied to gastric mucosa, rrespective of the site from which it has been aken.

010 CARCINOMA OF THE DUODENUM: ITS PREOPERATIVE DIAGNOSIS.

(Eng.) Satake, K.; Sowa, M.; Yamashita, K.; Kamino, K.; Kinoshita, H.; Kato, M.; Umeyama, K. (Osaka City Univ. Medical Sch., Osaka, Japan). *Br. J. Surg.* 62(12):973-976; 1975.

Two new cases of duodenal carcinoma are presented. In the first patient, a 65-yr-old man who had undergone gastrectomy for gastric ulcer 1 yr previously, a 2 x 3-cm filling defect of the distal duodenum with slight dilatation proximally was found in the upper gastrointestinal (GI) series following a 1-month history of malaise, weight loss, dull back pain, and vomiting. A well-localized tumor with ulceration in the center was seen on duodenoscopic examination; biopsy revealed a well-differentiated adenocarcinoma. In the second patient, a 35-yr-old man with a 7-month history of crampy, epigastric pain, upper GI examination showed a 2-cm ulcerating growth in the third portion of the duodenum and a 3 x 4-cm filling defect around the ulceration; the results of duodenoscopy revealed a 6 x 7-cm tumor, and biopsy showed a poorly differentiated adenocarcinoma. The treatment in both patients consisted of an extended pancreatoduodenectomy. Reconstruction was accomplished by suturing the common bile duct to the proximal end of the jejunum, implanting the pancreatic duct by direct suture of pancreas and jejunum in an end-to-side fashion, and constructing a gastrojejunostomy. There was no extension of the carcinoma through the duodenum and no lymph node metastases in the first patient, and he has been asymptomatic for 14 months. Although the tumor was larger in the second patient, he has been free of symptoms for 3 months. These cases and others in the literature suggest that duodenoscopy and biopsy are valuable in the diagnosis of this disease, and that they increase resectability and the 5-yr survival rate.

4011 URINARY POLYAMINE LEVELS IN PATIENTS WITH GASTROINTESTINAL MALIGNANCY.

(Eng.) Lipton, A.; Sheehan, L.; Harvey, H. A. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Cancer* 36(6):2351-2354; 1975.

A pilot study of urinary polyamine values was undertaken in 24 patients with localized and metastatic gastrointestinal tumors. Twenty-four-hr urine samples were obtained from 50 normal volunteers to establish a normal range for urinary polyamines. Polyamine values were obtained by high-voltage electrophoresis. The normal range for putrescine was 0.8 to 6.2 mg/24 hr; for spermidine, 0.9 to 3.9 mg/24 hr; and for spermine, 1.0 to 4.2 mg/24 hr. Eleven of 14 patients with widespread metastases had elevation of two or more of the polyamines. Putrescine was elevated (6.7-8.6 mg/24 hr) in three patients, two with primary adenocarcinoma arising in the sigmoid and one with primary adenocarcinoma arising in the rectum. Spermidine was elevated (3.9-15.9 mg/24 hr) in 11 patients and spermine was elevated (4.1-11.1 mg/24 hr) in 12 patients in whom the malignancies arose from an adenocarcinoma of the pancreas, rectum, sigmoid, colon, stomach, or rectosigmoid, or from an epidermal carcinoma of the anus. Two patients with localized colon cancer were compared with two patients with recurrence of the disease within the confines of the pelvis; all exhibited increased urinary excretion of two or three polyamines. In three patients who had a prior resection for gastrointestinal cancer and were clinically free of disease, the urinary polyamine values were within the normal range. Two patients with localized gastric lymphoma and one patient with villous adenoma also had normal urinary polyamine levels. These data suggest the following areas for further study: comparison of serum and urinary polyamine values to carcinoembryonic antigen in patients with Duke's

A, B, and C lesions; comparison of the value of serum and urinary polyamine values and carcinoembryonic antigen in evaluating the efficacy of surgery, radiation, or chemotherapy in patients with gastrointestinal malignancy; a comparison of the value of the high voltage electrophoresis method, amino acid analyzer, and radioimmunoassay of serum, urine, and colonic washings in different pathologic bowel conditions; and a study of polyamine values in bowel diseases that are known to lead to the development of malignancy in many patients.

4012 VALUE OF URINARY SIMPLE PHENOL AND INDICAN DETERMINATIONS IN THE DIAGNOSIS OF THE STAGNANT LOOP SYNDROME. (Eng.) Aarbakke, J.; Schjonsby, H. (Dept. Pharmacology, Univ. Bergen, MFH-Bygget, 5016 Haukeland Sykehus, Bergen, Norway). *Scand. J. Gastroenterol.* 11(4):409-414; 1976.

The urinary excretion of phenol, p-cresol, and indican was determined in 7 patients with the stagnant loop syndrome, 6 patients with celiac disease, 9 patients with chronic pancreatitis, 11 patients with Billroth II partial gastrectomy, and 18 control patients without gastrointestinal disease. The mean excretion of the compounds in the patients with the stagnant loop syndrome and in the control patients was 77 and 2.3 mg/24 hr of phenol ($p<0.05$), 164 and 39.5 mg/24 hr of p-cresol (not significant), and 369 and 41.5 mg/24 hr of indican ($p<0.01$), resp. When applied as diagnostic tests for the stagnant loop syndrome, the phenol excretion showed two false negative results; the p-cresol excretion showed three false negatives and two false positive results, and the indican excretion showed six false positive results. The combined use of phenol and indican determinations eliminated the number of false positive results with the indican test, and was found most useful as a screening procedure. Determination of phenol and indican in a 24-hr urine sample is likely to provide a simple method for selecting patients with signs of abnormal bacterial colonization in the small intestine for more detailed investigations.

4013 THE DIAGNOSIS OF GALLSTONES BY ULTRASONICS. (Ger.) Lutz, H.; Seidl, R.; Petzoldt, R.; Fuchs, H. F. (Medizinische Klinik mit Poliklinik der Universitat, 852 Erlangen, Krankenhausstr. 12, W. Germany). *Dtsch. Med. Wochenschr.* 100(24):1329-1331; 1975.

Ultrasonography, performed by a B-scan instrument in bidimensional technique, and radiological tests were compared in 267 patients suspected of having gallstones. Ultrasonic investigation was unevaluable in 9 patients due to adipositas or meteorism, while radiological pictures were unevaluable due to lack of opacification in 20 patients. The ultrasonic and radiologic findings were negative in 159 of the remaining 238 patients. Both methods gave positive findings concerning gallstones in 67 cases, which was confirmed surgically in 23 patients, by endoscopic retrograde scintigraphy in 4 patients, and by autopsy in 2 cases. The ultrasonic and radiologic findings were discordant in 12 cases. Surgery, performed in 7 of these 12 patients, confirmed the radiologic diagnoses in 4 cases and the ultrasonic findings in 3 cases. Solitary gallstones were visualized by ultrasonography as light-colored reflexes with an echo-free zone (shadow) behind them. Intense reflexes on the ventral surface of the stones and the corresponding shadows were seen when the gallbladder was filled with stones. Shadows without reflexes of the stones were seen in a few of these cases. The authors conclude that when cholelithiasis is suspected, ultrasonography is the choice diagnostic procedure because of its accuracy, simplicity, and the absence of any associated risk.

4014 OPERATIVE CHOLANGIOGRAPHY: A REAPPRAISAL BASED ON A REVIEW OF 400 CHOLANGIOGRAMS. (Eng.) Faris, I.; Thomson, J. P. S.; Grundy, D. J.; Le Quesne, L. P. (Dept. Surgical Studies, Middlesex Hosp. Medical Sch., London, England). *Br. J. Surg.* 62(12):966-972; 1975.

Experience with 400 cases of operative cholangiography is reviewed, and its usefulness in the diagnosis of stone in the common duct is compared with conventional clinical and operative indications. In 20.5% of the patients with stones in the common bile duct (CBD), there were neither clinical nor operative indications for choledochotomy, and the diagnosis was based solely on an abnormal cholangiogram. The rate of negative CBD explorations was 29%, compared to a rate of 28-44% reported elsewhere. False positives were most frequently due to air bubbles, which are avoidable. Contraction of the muscle surrounding the lower end of the duct, commonly caused by anesthetics, can give the appearance of a small stone. Inhalation of amyl nitrite can help clarify this situation. A normal operative cholangiogram saved 135 patients (36%) with indications for exploration from this unnecessary procedure. A significant increase in the diameter of the CBD occurs with age, which, if neglected, gives a misinterpretation of the cholangiogram in younger patients. The wider the duct, the greater is the chance of it harboring a stone. This study confirms that operative cholangiography is the best method for determining the presence of stones in the CBD.

4015 DOUBLE CONTRAST RADIOGRAPHY IN THE STUDY OF THE GASTRIC POSTERIOR WALL. (Fre.) Descombes, Ph.; Remond, A.; Capron, J. P.; Baillet, J.; Grumbach, Y.; Trinez, G. (C.H.U. place Victor-Pauchet, F 80000 Amiens, France). *J. Radiol. Electrol. Med. Nucl.* 57(1):1-6; 1976.

4016 MALABSORPTION. (Ger.) van de Kamer, J. H.; Wauters, E. A. K. (Wilhelmina Kinderziekenhuis, Nieuwegracht 137, Utrecht, Netherlands). *Schweiz. Med. Wochenschr.* 106(9):285-289; 1976.

4017 ENDOSCOPIC SEMEIOTICS AND DIAGNOSIS OF GASTRIC SARCOMAS. (Rus.) Savinkin, Iu. N.; Talalaeva, A. V. (P. A. Gertsen Moscow Scien-

LIBRARY U.

ific Res. Inst. Oncology, Moscow, USSR). *Khirur-ia (Mosk.)* (9):5-9; 1975.

018 CHROMOGASTROSCOPY IN DIAGNOSIS OF GASTRIC CANCER. (Rus.) Lukomskii, G. I.; Riab-sev, V. G.; Volkov, B. P.; Gido, Kh. M.; Biriukova, . S. (I. M. Sechenov First Moscow Medical Inst., oscow, USSR). *Khirurgiia (Mosk.)* (9):3-5; 1975.

019 VALUE OF SIALOGRAPHY IN SALIVARY GLAND TUMORS. STUDY OF 135 CASES. COMPARISON F RADIOLOGICAL, ANATOMIC AND CLINICAL FINDINGS. Fre.) Verhaeghe, M.; Lequint, A.; Adenis, L.; aurent, J. C.; Verhaegh, G. (Centre de Lutte contre e Cancer de la Region du Nord, France). *Lille Med.* 0(8):688-697; 1975.

020 ESOPHAGOGASTRODUODENOSCOPY IN THE DIAGNOSIS OF RECURRENT EMESIS IN CHILDHOOD. (Ger.) unte, A.; Gutzeit, D. (I. Med. Univ.-Klinik, Gastro-nterologische Abteilung, Ziemssenstrasse 1, D-8000 unich 2, W. Germany). *Monatsschr. Kinderheilkd.* 24(5):334-336; 1976.

4021 BENIGN LIVER TUMORS. THE VALUE OF HEPATO-TOMOGRAPHY IN PARACLINICAL EXAMINATIONS. (Fre.) Geindre, M.; Marty, F.; Vincent, J. (Departe-ment de Radiologie, C.H.U., F 38 000 Grenoble, rance). *J. Radiol. Electrol. Med. Nucl.* 6(Suppl. 1):29-30; 1975.

4022 STATE OF ART OF ENTEROSCOPY. (Ita.) Classen, M.; Demling, L. (Univ. Medical linic, 852 Erlangen, Krankenhausstr. 12, W. Ger-many). *Minerva Gastroenterol.* 21(4):254-257; 1975.

4023 NUCLEAR MEDICAL DIAGNOSTICS--PANCREATIC CARCINOMA. (Ger.) Schmidt, H. A. E. (Nuklearmed. Abt., Ev. Krankenhaus Bethesda, D-4100 Duisburg-1, Heerstr. 219, W. Germany). *Langenbecks Arch. Chir.* 339:247-251; 1975.

4024 VALUE OF LIVER BIOPSY IN THE DIAGNOSIS OF OCCULT FEVER. (Ger.) Malchow, H.; Roellinghoff, W. (Med. Univ.-Klinik, Abteilung I, D-7400 Tubingen, Otfried-Muller-Str. 10, W. Ger-many). *Internist (Berlin)* 16(9):436-443; 1975.

4025 INDICATIONS, LIMITS AND RELATIVE VALUE OF HEPATOGRAPHY, SELECTIVE ARTERIOGRAPHY, SCINTIGRAPHY AND ECHOTOMOGRAPHY IN THE DIAGNOSIS OF MALIGNANT LIVER TUMORS. (Fre.) Bollaert, A.; Ermans, A. E.; Lamarque, J. L.; Weill, F. (Service de Radiologie, Hopital Universitaire Saint-Pierre, Brussels, Belgium). *J. Radiol. Electrol. Med. Nucl.* 56(Suppl. 1):31-32; 1975.

4026 EARLY GASTRIC CARCINOMA. ENDOSCOPY OR RADIOLOGY? (Ger.) Miller, G.; Kaufmann, M. (Chirurgische Klinik des Burgerspitals, CH-4500 Solothurn, Switzerland). *Dtsch. Med. Wochenschr.* 101(26):1006-1010; 1976.

4027 ENDOSCOPY IN THE DIAGNOSIS OF HEMORRHAGES OF THE LOWER DIGESTIVE TRACT. (Fre.) Weill, J.-P.; Ekrschen, A. (Service d'Endoscopie, C.H.U., 67005 Strasbourg Cedex, France). *J. Med. Strasbourg* 6(14):855-858; 1975.

4028 HOW FAR CAN THE SERUM LEVEL OF CERTAIN PROTEIN FRACTIONS SERVE AS AN INDICATOR OR PARAMETER FOR DISEASES OF THE LIVER? (Ger.) Ohlenschlaeger, G.; Berger, I. (Gustav-Embden-Zentrum fur Biologische Chemie, Universitatsklinik Frankfurt, Frankfurt, W. Germany). *Fachz. Laboratorium* 20(7): 791-796; 1976.

4029 X-RAY DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF DUODENAL STENOSES IN INFANTS AND SMALL CHILDREN. (Ger.) Hoermann, D.; Himmel, D. (Klinik fur Kinderchirurgie, 7021 Leipzig, Theresienstrasse 43, E. Germany). *Kinderaerztl. Prax.* 43(12):554-563; 1975.

4030 DIAGNOSIS OF THE EXOCRINE PANCREAS. PART I: DIAGNOSTIC VALUE, METHODOLOGICAL ASPECTS AND STABILITY OF THE LIPASE AND α-AMYLASE ACTIVITY IN SERUM AND URINE. (Ger.) Poege, A. W.; Schwokowski, C. F. (Chirurgische Klinik der KMU, 701 Leipzig, Liebigstrasse 20a, E. Germany). *Z. Aerztl. Fortbild. (Jena)* 70(3):105-112; 1976.

4031 CLINICAL EXPERIENCE WITH ORAL CHOLEGRAPHY USING FALIGNOST WITH SPECIAL REFERENCE TO FRACTIONATED CHOLANGIOGRAPHY. (Ger.) Loreck, D.; Balzer, H. (Radiologische Klinik, Bezirkskrankenhaus Cottbus, 75 Cottbus, Thiemstrasse 111, E. Germany). *Z. Aerztl. Fortbild. (Jena)* 69(11):587-590; 1975.

4032 DETECTION OF MEMBRANE-BOUND IgG, HBsAG AND HBcAg ON ISOLATED HEPATOCYTES AND CRYOSTAT-FROZEN LIVER SECTIONS IN CHILDREN WITH CHRONIC INFLAMMATORY LIVER DISEASES. (Ger.) Baumann, W.; Arnold, W.; Meyer zum Bueschenfelde, K. H. (II. Medizinische Universitatsklinik und Poliklinik, Langenbeck-strasse 1, D-6500 Mainz, W. Germany). *Monatsschr. Kinderheilkd.* 124(5):487-488; 1976.

4033 RADIOLOGIC AND ENDOSCOPIC DIAGNOSIS. (Fre.) Vosse-Matagne, G. (Institut de Medecine, Universite de Liege, Liege, Belgium). *Rev. Med. Liege* 31(2):51-56; 1976.

4034 d-XYLOSE TEST FOLLOWING DIETARY LOAD AS A METHOD FOR THE FUNCTIONAL STUDY OF THE SMALL INTESTINE. (Rus.) Frol'kis, A. V.; Bushkova, R. K. (O. V. Kuusinen Petrozavodsk Univ., Petrozavodsk, USSR). *Klin. Med. (Mosk.)* 54(3):49-53; 1976.

4035 COMPUTER-AIDED DIAGNOSIS FOR PANCREATIC FUNCTION TEST. (Ger.) Thurmayr, R.; Thurmayr, R.; Otte, M. (Inst. fur Med. Datenverarbeitung der Ges. fur Strahlen- und Unweltforschung mbH, D-8000 Munich 81, Arabellastr. 4/I, W. Germany). *Langenbecks Arch. Chir.* 339:253-257; 1975.

4036 INTRAVENOUS CHOLANGIOGRAPHY IN CHILDREN. (Fre.) Chaumont, P.; Fortier-Beaulieu, M.; Garel, L.; Hamza, R.; Jeanson, C.; Kalifa, G.; Montagne, J. Ph. (Hopital de Bicetre, F 94270 Kremlin-Bicetre, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9):592-593; 1975.

4037 SCINTIGRAPHY OF THE LIVER, SPLEEN AND PANCREAS: GALLIUM SCINTIGRAPHY. (Ger.) Grebe, S. F. (Zentrum f. Radiologie d. Universitat, Friedrichstr. 27, 6300 Giessen, W. Germany). *Therapiewoche* 26(5):832-840; 1976.

4038 RETROGRADE ENDOSCOPIC CHOLANGIOPANCREATICOGRAPHY (ERCP). TECHNICAL ASPECTS AND DIAGNOSTIC-THERAPEUTIC VALUE. (Nor.) Osnes, M.; Myren, J.; Swenssen, T. (Ulleval sykehus, Avdeling IX, Norway). *Tidsskr. Nor. Laegeforen.* 95(27): 1529-1534; 1975.

4039 IMPROVEMENT OF INTRAVENOUS CHOLANGIOGRAPHY. IS REINJECTION ALLOWABLE? (Fre.) Weissman, A.; Paillard, M.; Brault, P.; Agratina, J.; Grellet, J. (Hopital Louis-Mourier, F 92700 Colombes, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9): 591-592; 1975.

4040 HEPATIC HEMANGIOMATOSIS IN INFANTS: DIAGNOSIS AND TREATMENT. (Fre.) Braun, P.; Ducharme, J. C.; Davignon, A. (Hopital cantonal, 30, bd de la Cluse, CH-1205 Geneva, Switzerland). *Helv. Paediatr. Acta* 30(2):159-167; 1975.

4041 TRANSHEPATIC CHOLANGIOGRAPHY IN CHILDREN. (Fre.) Chaumont, P.; Hamza, R.; Harry, G. (Hopital de Bicetre, F 94270 Kremlin-Bicetre, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9): 626-627; 1975.

4042 RENAL COMPLICATIONS IN BILIARY OPACIFICATIONS. (Fre.) Ganeval, D.; Grunfeld, J. P.; Franco, D.; Moreau, J. F.; Daniel, F. (Hopital Necker, 161, rue de Sevres, F 75730 Paris Cedex 15, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9): 616-618; 1975.

4043 ACCIDENTS IN INTRAVENOUS CHOLANGIOGRAPHY. RESULTS OF AN INVESTIGATION BY THE FRENCH RADIOLOGY SOCIETY. (Fre.) Nahum, H.; Desbleds, M.-T.; Marsault, C. (Hopital Beaujon, F 92110 Clichy, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9): 595-597; 1975.

4044 ISOLATED OPACIFICATION OF THE MAIN BILE DUCT IN ORAL CHOLECYSTOGRAPHY. (Fre.) Vadrot, D.; Benchetrit, J.; Johner, J.; Mouzon, A.; Doyon, D. (Hopital de Bicetre, F 94270 Kremlin-Bicetre, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9):605; 1975.

4045 TRANSPARIETAL CHOLANGIOGRAPHY. (Fre.) Diard, F.; Marsault, C.; Huguet, C.; Bigot, J. M. (Hopital Saint-Andre, F 33000 Bordeaux, France) *J. Radiol. Electrol. Med. Nucl.* 56(8/9):622-626; 1975.

4046 BEHAVIOR OF SERUM GASTRIN DURING VAGAL STIMULATION WITH 2-DEOXY-D-GLUCOSE IN CONSIDERATION FOR ACID SECRETION AND MUCOSAL HISTOLOGY. (Ger.) Kayasseh, L.; Stalder, G. A. (Medizinische Universitatspoliklinik, Hebelstrasse 1, CH-4004 Basel, Switzerland). *Schweiz. Med. Wochenshcr.* 106(9):303-305; 1976.

4047 A STUDY OF THE GASTRIC SECRETORY FUNCTION IN ELDERLY PATIENTS. (Rus.) Korkushko, O. V.; Kotko, D. N.; Iakimenko, D. M.; Voloshchenko, I. I. (Inst. Gerontology, USSR Acad. Medical Sciences Kiev, USSR). *Vrach. Delo* (9):57-59; 1975.

4048 A COMPARATIVE STUDY OF LABORATORY TESTS FOR PROVING THE PRESENCE OF CHOLESTASIS. (Bul.) Adzharov, D.; Ivanov, E. (Center Hygiene, Medical Acad., Bulgaria). *Suvrem. Med.* 26(6):20-28; 1975.

4049 GASTRIN ANTIBODIES (IgA) IN THE BLOOD OF HEALTHY HUMAN SUBJECTS AND ANIMALS. (Rus.) Polosatov, M. V.; Samartsev, M. A.; Klimov, P. K.; Prusakov, A. N. (I. P. Pavlov Inst. Physiology, USSR Acad. Sciences, Leningrad, USSR). *Dokl. Akad. Nauk SSR* 225(1):235-237; 1975.

4050 COMPARISON OF THE RESULTS OF SEVERAL METHODS FOR THE DISCOVERY OF AUSTRALIA ANTIGEN IN THE SERA OF PATIENTS SUFFERING FROM CHRONIC LIVER AND GASTROENTEROLOGIC DISEASE. (Bul.) Maleev, At.; Ognianov, M.; Baleva, M.; Bradistilova, D. (Faculty Medicine Medical Acad., Sofia, Bulgaria). *Suvrem. Med.* 26(7):11-14; 1975.

4051 CYTOLOGICAL DIAGNOSIS OF POLYPS OF THE RECTUM. (Rus.) Lazarev, I. M. (Moldavian Scientific Research Inst. Oncology, Kishinev, USSR). *Arkh. Patol.* 37(5):70-75; 1975.

4052 THE CONTRIBUTION MADE BY AIMED BIOPSY IN GASTROSCOPY IN THE DIAGNOSIS OF PRIMARY GASTRIC CANCER. (Ita.) Liguory, Cl.; Caletti, G. C. (Policlinico S. Orsola, Bologna, Italy). *Minerva Med.* 66(48):2311-2313; 1975.

LIBRARY U.

4053 A COMPARATIVE STUDY OF DIFFERENT METHODS FOR THE DETECTION OF GASTROESOPHAGEAL REFLUX. (Spa.) Rufin D., F.; Davila S., C. M. Hospital San Juan de Dios, Santiago, Chile). *Rev. Med. Chile* 103(1):22-25; 1975.

4054 IMMUNOCHEMICAL DETERMINATION OF α-FETOPROTEIN IN DYNAMICS OF DEVELOPMENT OF CIRRHOSIS OF THE LIVER AND HEPATOCELLULAR CANCER. (Rus.) Afanas'eva, K. A.; Ragozin, Iu. E.; Tatarinov, Iu. S. (A. V. Lunacharskii Astrakhan Medical Inst., Astrakhan, USSR). *Vestn. Akad. Med. Nauk SSSR* (6):71-73; 1975.

4055 RADIOLOGICAL DIAGNOSIS AND ENDOSCOPIC CURE OF DYSPHAGIA IN A CASE OF THE KELLY-PATERSON SYNDROME. (Fre.) Treheux, A.; Gaucher, P.; Fays, J.; Straub, J.; Bigard, M. A.; Chaplain, G.; Laugros, A. (C.H.R., 29, avenue du Marechal-de-Lattre-de-Tassigny, F 54037, Nancy Cedex, France). *J. Radiol. Electrol. Med. Nucl.* 57(2):165-166; 1976.

4056 TRYPTIC AND CHYMOTRYPTIC ACTIVITY IN THE FECES OF CHILDREN OF DIFFERENT AGE GROUPS. (Ger.) Saelzer, K.; Kobayashi, Y.; Tolckmitt, W. (Klinikum der Justus-Liebig-Universitat, Feulgenstrasse 12, D-6300 Giessen, W. Germany). *Eur. J. Pediatr.* 121(4):279-285; 1976.

4057 CAUSES OF ERRONEOUS ROENTGENOLOGICAL DIAGNOSIS OF DIGESTIVE TRACT DISEASES. (Rus.) Tret'iakova, T. A.; Teremetskii, L. G. Ovchinnikova, V. I. (S. P. Botkin Clinical Hosp., Moscow, USSR). *Vestn. Khir.* 115(9):117-122; 1975.

4058 APPLICATION OF THE IMPEDANCE MEASUREMENT METHOD IN THE LARGE INTESTINE. (Ger.) Nedbal, J.; Setka, J.; Vrana, J.; Kudrmann, J.; Hledik, E. (Krankenhaus Bulovka, Prague 8, Czechoslovakia). *Schweiz. Med. Wochenschr.* 106(9):312-314; 1976.

4059 EXOCRINE FUNCTION OF THE PANCREAS AFTER VAGOTOMY WITH LIMITED GASTRIC RESECTION. (Rus.) Postolov, P. M.; Fetisov, V. A.; Baido, V. P.; Kiselev, Iu. I. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Vestn. Khir.* 115(8):8-12; 1975.

4060 DIAGNOSTIC VALUE OF INFUSION DRIP CHOLECYSTOCHOLANGIOGRAPHY. (Rus.) Seleznova, S. I.; Kuznetsov, V. G. (Dnepropetrovsk Scientific Research Inst. Gastroenterology, Dnepropetrovsk, USSR). *Vrach. Delo* (9):51-55; 1975.

4061 ISOENZYMES OF ASPARTIC AMINOTRANSFERASE IN THE DIAGNOSIS OF VIRAL HEPATITIS. (Rus.) Malinovskii, Iu. I. (Lvov Medical Inst., Lvov, USSR). *Vrach. Delo* (9):138-139; 1975.

4062 ANGIOGRAPHY IN CANCER OF THE STOMACH. (Rus.) Riabtsev, V. G.; Filimonov, G. P.; Savchenko, A. P.; Golubkov, V. A. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Sov. Med.* (10):43-47; 1975.

4063 ALPHA-FETOPROTEIN IN MALIGNANT AND NON-MALIGNANT LIVER DISEASE. (Rus.) Ruoslakhti, E.; Seppialia, M.; Pikhko, Kh. (Central Hosp., Helsinki Univ., Helsinki, Finland). *Sov. Med.* (10):116-118; 1975.

4064 SCANNING OF THE LIVER WITH LABELED COLLOID SOLUTION AND METHIONINE. (Rus.) Palinkashi, D. G.; Prokubovskii, V. P. (N. I. Pirogov Second Moscow Medical Inst., Moscow, USSR). *Med. Radiol. (Mosk.)* 20(11):35-39; 1975.

4065 EMERGENCY FIBEROPTIC GASTROSCOPY IN HEMORRHAGES FROM UPPER GASTROINTESTINAL TRACT. (Rus.) Gallinger, Iu. I.; Kliavin, Iu, A.; Ezhova, G. I.; Sokolov, L. K.; Ivanov, V. F. (N. I. Pirogov Second Moscow Medical Inst., Moscow, USSR). *Khirurgiia (Mosk.)* (9):29-34; 1975.

4066 IMPORTANCE OF LIVER RHEOGRAPHY FOR DIFFERENTIAL DIAGNOSIS OF OBSTRUCTIVE JAUNDICE. (Rus.) Streletskii, G. N.; Vasilenko, I. S. (Kursk Medical Inst., Kursk, USSR). *Khirurgiia (Mosk.)* (9):96-101; 1975.

4067 ENDOSCOPIC DIAGNOSIS OF MASKED PERFORATED GASTRODUODENAL ULCER. (Rus.) Bebiia, N. V. (S. M. Kirov Military Medical Acad., Leningrad, USSR). *Vestn. Khir.* 115(12):25-28; 1975.

4068 AN EXPERIMENTAL STUDY OF SELECTIVE MESENTERICOGRAPHY IN ACUTE INTESTINAL OBSTRUCTION. (Rus.) Shal'kov, Iu. L.; Levendiuk, A. M.; Beresnev, A. V.; Slyshkov, V. P. (Kharkov Scientific Res. Inst. General and Emergency Surgery, Kharkov, USSR). *Vestn. Khir.* 115(12):35-38; 1975.

4069 CLINICO-GASTROSCOPIC AND ROENTGENOLOGICAL DATA IN THE DIAGNOSIS OF CHRONIC PRIMARY GASTRODUODENITIS. (Rus.) Vasilenko, A. M.; Khodykin, A. V.; Enokhovich, V. A.; Zdesenko, P. P.; Volosevich, N. V. (6th Municipal Hosp. of Krivoy Rog, Krivoy Rog, USSR). *Vrach. Delo* (12):33-37; 1975.

4070 COMPARATIVE STUDY BASED ON GAMMAGRAPHY AND ARTERIOGRAPHY OF LESIONS OCCUPYING HEPATIC SPACE. (Spa.) Luque, M. T.; Rius, J. M.; Galofre, P.; Domenech-Torne, F. M. (Servicio de Medicina Nuclear, Ciudad Sanitaria de la Seguridad Social Francisco Franco, Barcelona, Spain). *Med. Clin. (Barc.)* 64(1):11-14; 1975.

LIBRARY U.

4071 DIAGNOSTIC VALUE OF "TRANSPARIETOHEPATIC CHOLANGIOGRAPHY." Matuk M., A.; Tawil M., M.; Castro R., H. (Facultad de Medicina, Universidad Javeriana, Bogota, Colombia). *Univ. Med.* 17(1): 44-48; 1975.

4072 THE VALUE OF TOMO-ECHOGRAPHY FOR THE DIAGNOSIS OF HYDATIDS OF THE LIVER. (Fre.) Seror, J. (Hopital civil, Pavillon Chirurgical B, 67000 Strasbourg, France). *Ann. Chir.* 29(9):795-796; 1975.

4073 THE PLACE OF FIBEROPTIC COLONOSCOPY IN THE DIAGNOSIS OF COLONIC DISEASES. (Pol.) Nowak, A.; Czarnecka, K.; Rybicka, J.; Zmudzinska, M.; Toborek, N. (Instytut Chorob Wewnetrznych, 40-752 Katowice-Ligota, ul. Medykow 14, Poland). *Pol. Arch. Med. Wewn.* 54(3/9):297-304; 1975.

4074 LONG-TERM INTRAVENOUS INFUSION OF INDOCYANINE GREEN FOR DIAGNOSIS OF LIVER DAMAGE. (Pol.) Caban, M. (Instytut Medycyny Wewnetrznej Akademii Medycznej, ul. Kopernika 15, Krakow, Poland). *Pol. Arch. Med. Wewn.* 54(4/10):339-344; 1975.

4075 HEARTBURN AND GASTROESOPHAGEAL REFLUX STUDIES BY THE WATER-SIPHON METHOD. (Pol.) Staniczek, J.; Lisowska, R. (Katedra i Zaklad Radiologii Sl. AM, ul. Piastow 22/29, 40-686 Katowice, Poland). *Pol. Tyg. Lek.* 30(46):1919-1920; 1975.

4076 ECONOMICALLY STANDARDIZED X-RAY EXAMINATION OF THE STOMACH. (Ger.) Dihlmann, W. (Allgemeines Krankenhaus Barmbek, 2000 Hamburg 60, Ruebenkamp 148, W. Germany). *Dtsch. Med. Wochenschr.* 101(23):900-904; 1976.

4077 EFFECTS OF HIGH INTENSITY ULTRASOUND ON INTRAORGANIC VESSELS OF THE LIVER. (Rus.) Sheik-Khassan, O. (I. P. Pavlov First Leningrad Medical Inst., Leningrad, USSR). *Arkh. Anat. Gistol. Embriol.* 69(10):93-98; 1975.

4078 USE OF GALLIUM RADIOISOTOPE IN THE DIAGNOSIS OF RETROPERITONEAL TUMORS. (Cze.) Pavlova, A.; Bechyne, M. (III. interni klinika fakulty vseobecneho lekarstvi, University Karlovy, Prague, Czechoslovakia). *Cas. Lek. Cesk.* 115(15): 465; 1976.

4079 THE SIGNIFICANCE OF BENGAL RED LABELING FOR THE EVALUATION OF THE ACTIVITY OF THE HEPATIC PARENCHYMA. (Pol.) Kuydowicz, J. (Klinika Chorob Zakaznych IMW AM, 91-347 Lodz, ul. Kniaziewicza 1/3, Poland). *Pol. Tyg. Lek.* 31(24):1047-1049; 1976.

4080 ORAL OVERLOAD TEST WITH D-XYLOSE. (Spa.) Zarragoitia Rodriguez, O. L.; Corral, J. P.; Savigne, M. R. (Hospital Pediatrico Docente de Centro Habana, Havana 6, Cuba). *Rev. Cub. Pediatr.* 47(3): 361-365; 1975.

4081 SIGNIFICANCE OF SERUM GASTRIN ANALYSIS FOR FUNCTIONAL ULCER SURGERY. (Ger.) Saeuberli, H.; Largiader, F.; Vetter, W.; Deyhle, P. (Chirurgische Universitatsklinik A, Kantonsspital, Ramistrasse 100, CH-8006 Zurich, Switzerland). *Helv. Chir. Acta* 42(1/2):185-188; 1975.

4082 AMINOPYRINE RESPIRATION TEST, A NEW METHOD FOR THE DETERMINATION OF LIVER FUNCTION. (Ger.) Platzer, R.; Gikalov, I.; Kuepfer, A.; Bircher, J.; Preisig, R. (Institut fur Klinische Pharmakologie der Universitat, Murtenstrasse 35, CH-3010 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 106(9):317-318; 1976.

4083 THE VALUE OF RADIOLOGICAL INVESTIGATION IN THE DIAGNOSIS OF DUODENAL CAP ULCER. (Pol.) Kulicz, A. (Zaklad Radiologii Sl. AM, Zabrze, Bytom, Poland). *Pol. Tyg. Lek.* 30(47):1961-1962; 1975.

4084 ROENTGENODIAGNOSIS OF DIVERTICULOSIS AND DIVERTICULITIS OF THE LARGE INTESTINE. (Rus.) Shniger, N. U. (Scientific Res. Laboratory and Proctology Clinic, Russian SSR Ministry of Health, Moscow, USSR). *Vestn. Rentgenol. Radiol.* (6):33-39; 1975.

4085 FIBER COLOSCOPY WITH SPECIAL REGARD TO PARTIAL RECTOSIGMOIDOSCOPY. (Ger.) Brandstaetter, G.; Kratochvil, P. (II. Medizinische Abteilung, Landeskrankenhaus, Auenbruggerplatz 1, A-8036 Graz, Austria). *Wien. Med. Wochenschr.* 125(46):661-663; 1975.

4086 GASTROINTESTINAL HORMONES AND BLOOD CIRCULATION IN THE GASTRIC MUCOSA. (Ger.) Koch, H. (Med.-Klinik und Poliklinik, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Z. Gastroenterol.* 14:105-109; 1976.

4087 SIGNIFICANCE OF SCANNING IN THE DIAGNOSIS OF LIVER CIRRHOSIS. (Rus.) Fedyshin, P. S.; Vasil'eva, V. S.; Furmanenko, E. D. (Municipal Hosp. No. 6, Kiev, USSR). *Vrach. Delo* (11):67-71; 1975.

4088 COMPARATIVE EXAMINATION OF GASTRIC ACID FORMATION BY THE RADIOTELEMETRIC AND TUBE METHODS. (Rus.) Ivashin, V. T. (S. M. Kirov Military Medical Acad., Leningrad, USSR). *Vrach. Delo* (12):37-40; 1975.

4089 A CLINICAL-RADIOLOGICAL INVESTIGATION CONCERNING THE ACCURACY OF DIATRIZOATE (GASTROGRAFIN) IN THE DEMONSTRATION OF ANASTOMOSIS DEHISCENCE AND PERFORATION OF THE GASTROINTESTINAL TRACT. (Ger.) Riedl, P.; Dinstl, K.; Keminger, K.; Lechner, G.; Schiessel, R. (I. Chirurgische Univ.-Klinik, A-1097 Vienna, IX. Alserstrasse 4, Austria). *Fortschr. Roentgenstrahl.* 124(1):48-51; 1976.

4090 CARCINOMA OF THE PANCREAS: CONVENTIONAL ROENTGENOLOGIC PROCEDURES. (Ger.) Frommhold, W. (Med. Strahleninst, d. Univ., D-7400 Tubingen, Rontgenweg 11, W. Germany), *Langenbecks Arch. Chir.* 339:229-237; 1975.

4091 THE VALUE OF BLOOD LIPASE ASSAY IN THE DIAGNOSIS OF ACUTE PANCREATITIS. (Fre.) Bunodiere, M.; Soria, P.; Mathey, J.-C.; Boury, G.; Houdard, Cl. (Service de Chirurgie Digestive, Hopital Tenon, 4, rue de la Chine, 75020 Paris, France). *Ann. Chir.* 29(6):571-575; 1975.

4092 THE pH OF THE STOMACH IN THE PRE- AND POST-OPERATIVE ASSESSMENT OF GASTRODUODENAL ULCERS: A STATISTICAL STUDY OF 206 CASES. (Fre.) Boury, G.; Mathey, J.-C.; Gautier, C.; Houdard, Cl. (Service de Chirurgie Digestive, Hopital Tenon, 4, rue de la Chine, 75020 Paris, France). *Ann. Chir.* 29(6): 545-548; 1975.

4093 EXTENDED CARBOXYANGIOGRAPHY IN THE EXPLORATION OF THE LIVER. CONTRIBUTION OF A NEW PHLEBOGRAPHIC METHOD. (Fre.) Bendib, M.; Toumi, M.; Boudjellab, A. (Service Central de Radiologie du C.H.U. de Mustapha Alger, Mustapha Alger, Algeria). *Med. Chir. Dig.* 3(4):237-245; 1974.

4094 ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATICOGRAPHY. (Ger.) Kratochvil, P.; Brandstaetter, G.; Spielhofer, A. (2. Medizinische Abteilung, Landeskrankenhaus, Auenbruggerplatz, A-8036 Graz, Austria). *Wien. Klin. Wochenschr.* 88(1): 9-15; 1976.

4095 THE EFFECTS OF STIMULATING THE ESOPHAGOGASTRIC SPHINCTER WITH HYDROCHLORIC ACID.

(Rum.) Vlad, C. M. (Catedra de fiziologie, I.M.F., Bucharest, Rumania). *Fiziol. Norm. Patol.* 19(1):75-84; 1973.

The eventual effect of hydrochloric acid (HCl) stimulation on the behavior of the esophagogastric sphincter was investigated in 14 control subjects with normal sphincters and in five subjects with sphincteral hypotonia confirmed by manometrical measurements. The results were evaluated by pressure-tracing recorded with a Barovar-Barostyl Alvar electromanometer. The introduction of 5 ml distilled water at room temperature through a catheter placed at the level of the esophagogastric junction for a duration of 5 min induced a sudden pressure increase of 3-4 min duration in the 14 control subjects; subsequent introduction of HCl (5 ml at pH 1.6, equivalent to 25 mEq/l) through the same catheter and for the same duration determined an almost identical pressor effect. Both pressor effects were absent in the five patients with an insufficient sphincter. The author concludes that a normal, competent sphincter is not affected by the presence of small quantities of HCl introduced by experimental methods or by occasional gastric reflux.

4096 LONG-TERM CLINICAL, RADIOLOGICAL AND MANOMETRIC FOLLOW-UP OF PATIENTS WITH ACHALASIA OF THE ESOPHAGUS TREATED WITH ESOPHAGOMYOTOMY.

(Eng.) Csendes, A.; Larrain, A.; Strauszer, R.; Ayala, M. (Centro de Gastroenterologia, Hospital J. J. Aguirre, Santiago, Chile). *Digestion* 13(1/2):27-32; 1975.

The effects of esophagomyotomy on the clinical symptoms, resting gastroesophageal sphincter pressure (GESP), and the maximal internal diameter of the esophagus were studied in 20 patients who underwent surgery for esophageal achalasia. The surgical approach was transabdominal, and an anterior esophagomyotomy with a fundic patch was performed in all cases. One case was lost to follow up, and the rest were observed for a mean of 34 months (12-72 months). All but one patient became asymptomatic after surgery; dysphagia persisted in this patient because of a small stenosis at the esophagogastric junction, which was corrected by dilation. Before surgery, the mean diameter of the lumen of the gastroesophageal junction was 2.95 mm during barium flux; the diameter was significantly increased to 9.31 mm 1 month after surgery and was maintained throughout the observation period. The mean maximal internal diameter of the middle third of the thoracic esophagus was 5.15 cm; this was reduced to 3.28 cm after treatment. The mean resting GESP was 28.8 mm Hg before surgery, and was significantly decreased to 6.30 mm Hg following surgery. Late examination in 17 asymptomatic patients showed a mean GESP of 6.23 mm Hg. These preliminary results favor the use of esophagomyotomy in treating esophageal achalasia.

4097 TRANSIENT POST-VAGOTOMY DYSPHAGIA: A DISTINCT CLINICAL AND ROENTGENOGRAPHIC ENTITY.

(Eng.) Rogers, L. F. (McGaw Medical Center of Northwestern Univ., 303 E. Chicago Ave., Chicago, IL 60611). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(4):956-960; 1975.

Clinical and roentgenographic features of five cases of transient postvagotomy dysphagia are described. All patients underwent a transabdominal vagotomy for ulcer disease. In two patients, a Bilroth I partial gastrectomy was performed, and three patients underwent a pyloroplasty. Two patients also underwent simultaneous cholecystectomy. The time of onset of dysphagia varied from the 7th to the 15th postoperative day. In each case it was painless and associated with the initial ingestion of solid foods. Treatment in both cases consisted of temporary dietary exclusion of solid foods and of single passage of a number 18 Levin tube in one case and a single bougienage of a number 48 French bougie in another. The symptoms were completely relieved in all patients in 10-30 days. The typical roentgenographic finding was a smooth, tapered, persistent, narrowing of the distal 3-4 cm of the esophagus. The transverse diameter of the narrowed segment of the lumen measured 2-4 mm. The offending bolus of solid food was identified within the barium column at the site of tapering. The results show tha dysphagia is a transient postvagotomy disorder that requires no treatment other than the temporary exclusion of solid foods and the passage of a narrow tube.

4098 SCANNING WITH ^{99m}Tc IN THE DIAGNOSIS OF BARRETT'S ESOPHAGUS.

(Spa.) Culebras Fernandez, J. M.; Manrique Legaz, A. J.; Moreno Gonzalez-Bueno, C.; Ortiz Berrocal, J. (Servicio Cirugia Aparato Digestivo, Fundacion Jimenez Diaz, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 45(6):669-680; 1975.

The presence of columnar epithelial lining in the esophagus (Barrett's esophagus) was demonstrated by ^{99m}Tc scintiscan in a 9-yr-old boy with radiologically and endoscopically confirmed esophagostenosis of about 6-months duration. The study was carried out in a "Nuclear Chicago Pho Gamma III, H.P." gamma chamber, equipped with a high sensitivity collimator suitable for 140 kilo electron volts. The ^{99m}Tc was administered as pertechnetate (5 mCi, i.v.), and the scintiscans were recorded at a density of 300,000 counts per image. The scintiscans registered 10 and 15 min after the injection showed clear outlines of the stomach and lower third of the esophagus. After 20 min, an uptake zone was seen in the upper part of the esophagus at the level of the thyroid gland; the activity profile of a sagittal section through this zone showed three peaks of activity corresponding to the gastric antrum, lower esophagus, and thyroid gland. The scintiscans confirmed previous contrast radiology findings, which showed concentric stenosis in the lower third of the esophagus and hiatal hernia with abundant gastroesophageal reflux. Following esophagocologastrostomy, the histopathologic examination of the surgical specimen revealed fibrosis at the esophagogastric junction, with disappearance of the normal structures. The authors state that ^{99m}Tc uptake concentrated in the esophageal region is an unequivocal sign of gastric-type columnar epithelial lining, which, in turn, indicates the benignancy of the process. In view of the many similarities between peptic stenosis and carcinoma, this method is an effective tool in differential diagnosis. Its disadvantages were seen only in rare cases of neoplasms that developed over a peptic stenosis with conservation of some columnar epithelium, in which case ^{99m}Tc uptake gave an erroneous diagnosis of benignancy.

STOMACH

4120 GASTRIC ANTRAL DIAPHRAGM. (Eng.) Cho, K. J. (Univ. Michigan at Wayne County General Hosp., Eloise, MI 48132). *Gastrointest. Radiol.* 1(1):37-40; 1976.

Roentgenographic abnormalities in three patients (a 50-yr-old woman, a 57-yr-old man, and a 55-yr-old woman) with antral diaphragm are presented. The apertures were 3.0 mm-1.2 cm in diameter and were 1-3 cm proximal to the pylorus. Barium studies revealed the diaphragm to be a persistent, circumferential defect, often associated with peptic ulcers or gastric outlet obstruction. At endoscopy, the central aperture did not change during peristalsis, in contrast to the pylorus, which changes. Although the mucosa of the diaphragm has been normal in most of the previously reported cases, gastroscopy revealed erosion and erythema of the antral mucosa in these patients. Since surgical excision of the antral diaphragm can cure the patient's symptoms, a correct diagnosis by both upper gastrointestinal examination and endoscopy is important.

4121 GASTRIN RESPONSE TO CALCIUM AND SECRETIN INFUSION IN PATIENTS WITH ACHLORHYDRIA. (Eng.) Turnipseed, W. D.; Keith, L. M., Jr.; Takeuchi, O. (Ohio State Univ. Coll. Medicine, Columbus, OH). *Surg. Forum* 26:355-357; 1975.

Gastric pH was determined in 15 patients with achlorhydria, and the effect of calcium and secretin infusions on gastrin concentrations was studied. The mean gastric pH in the achlorhydric patients was 7.1, while the mean pH in 15 controls was 1.9. The basal gastrin levels in the patients with achlorhydria was 891 pg/ml, while that in the controls was only 84 pg/ml. In the patients with achlorhydria with no demonstrable antral disease, the mean gastrin level was 1,509 pg/ml, while in the achlorhydric patients with severe antral gastritis, it was only 185 pg/ml. A 200% increase in the gastrin concentration occurred after i.v. calcium infusion in three achlorhydric patients with pernicious anemia without antral gastritis. No response occurred in two patients with pernicious anemia with antral gastritis, one patient with atrophic gastritis without antral involvement, two patients with atrophic gastritis with antral involvement, or in eight controls. Secretin depressed gastrin levels by 25-35% in patients and controls. The results suggest that gastric pH directly influences the production and/or release of gastrin, that severe antral disease depresses gastrin levels, and that antral mucosal cells with altered endocrine function may exist in pernicious anemia.

4122 EROSIVE HEMORRHAGIC GASTRODUODENITIS WITH FIBRINOLYSIS AND LOW FACTOR XIII. (Eng.) Nilsson, I. M.; Bergentz, S.-E.; Wiklander, O.; Hedner, U. (Malmo General Hosp., Univ. Lund, Malmo, Sweden). *Ann. Surg.* 182(6):677-682; 1975.

The case reports and the results of platelet and coagulation studies and of fibrinolytic studies performed in four patients with erosive hemorrhagic gastroduodenitis and high fibrinolytic activity of the gastric juice are presented. No increase in the fibrinolytic activity could be demonstrated in the circulating blood. However, the values found for fibrinogen, plasminogen, and α_2-macroglobulin were 0.25-0.45 g/100 ml (normal 0.20-0.40 g/100 ml), 35-60% (normal 60-140%), and 49-74% (normal 80-120%), resp. A high content of fibrin/fibrinogen degradation products (FDP; 7.5-38 μg/ml, normal 0-10 μg/ml) was found in the serum. All patients had a markedly decreased content of factor XIII (6-13 U, normal l-31 U). Platelet count and other coagulation omponents were normal. These findings were interreted as signs of local fibrinolysis in the lseased parts of the gastrointestinal canal. The leeding stopped after p.o. and i.v. administration f a fibrinolytic inhibitor and of factor XIII-ontaining concentrate. In bleeding from gastrouodenal ulcer and esophageal varices, no increase n gastric fibrinolytic activity was found. The high ocal fibrinolytic activity in the stomach in erosive astritis together with the low content of factor III may contribute substantially to the hemorrhage n this condition. These observations may lead to revision of the treatment of such cases.

123 PATTERNS OF GASTRITIS IN ALCOHOLICS.

(Eng.) Pitchumoni, C. S.; Glass, G. B. J. New York Medical Coll., New York, NY 10029). *ol. Gastroenterol. (Paris)* 9(1):11-16; 1976.

ucosal biopsies were obtained simultaneously by lber-gastroscopy from the fundus and antrum of 100 lcoholics (daily consumption of over 200 g of thanol for an average of 13 yr) and from 80 nonaloholic, age- and sex-matched controls. In the erum of the controls and 61 of the alcoholics and n normal rat gastric mucosa, parietal cell antiodies were determined. Moderate or severe antral astritis with no or only mild fundic lesions was ound in 46 alcoholics, while 25% of the controls ad this lesion. Early or advanced atrophic fundal astritis was the only lesion in 12 alcoholics. In ne controls, superficial fundic gastritis was ound in 17%, and advanced fundic gastritis was ound in 4%. Although the fundic mucosa was normal n 61 of the alcoholics, that of the antrum was noral in only 26 alcoholics. Chronic alcohol abuse ignificantly increases the incidence of chronic ntral gastritis ($p<0.005$). The prevalence of parital cell antibody was similar in the controls and n the 61 alcoholics tested, both men (6.5 and 7%, esp.) and women (13.5 and 10%, resp.). The prealence of the antibody occurred in 6.7% of the hronic alcoholics with normal mucosa, in 10% of ne alcoholics with superficial gastritis, and in 7.5% of those with combined fundal and antral gasritis. As an extension of the Strickland nomenlature, the authors propose the designation "type B" gastritis for the group of cases with involveent of the antrum and fundus.

124 HETEROGENEITY IN SUSCEPTIBILITY TO CHRONIC GASTRITIS IN RELATIVES OF GASTRIC CANCER ATIENTS WITH DIFFERENT HISTOLOGY OF CARCINOMA.

Eng.) Kekki, M.; Ihamaki, T.; Sipponen, P.; ovinen, E. (Dept. Medicine, Univ. Helsinki, Helinki, Finland). *Scand. J. Gastroenterol.* 10(7): 37-745; 1975.

he morphological state of gastric body mucosa was xamined in 269 first-degree relatives of 64 index atients with gastric carcinoma and in 142 subjects elected at random. Gastric carcinoma was divided nto three groups according to histological properies: carcinoma mucocellular (diffuse type carcinoma, producing intracellular mucins), carcinoma adenomatosum (intestinal type, malignancies displaying well-formed adenomatous structure), and carcinoma anaplasticum (poor histological structural differentiation, poor formation of mucin). The state of gastric body mucosa was divided into five stages: normal and superficial gastritis and slight, moderate, and severe atrophic gastritis. The results were subjected to the numerical analysis based on the stochastic theory. The term "age-adjusted score" (AAS) defines the individual susceptibility to chronic gastritis. In terms of AAS, the material could be divided into high and low gastritis risk families. The subjects belonging to carcinoma mucocellular index patient families had a significantly higher susceptibility to chronic gastritis (mean AAS-0.51 ± 1.18) than the other relatives examined (-0.12 ± 0.97 and 0.08 ± 1.29 for carcinoma adenomatosum and anaplasticum, resp.). These families were also significantly concentrated in the group of high risk families. The heterogeneity of the relatives of gastric cancer patients, as regards their gastritis risk, should be taken into account in future epidemiological studies. These findings support the genetic approach to studies concerning a gastritis-gastric cancer relation.

4125 EFFECT OF GASTRIC BYPASS ON GASTRIC SECRETION.

(Eng.) Mason, E. E.; Munns, J. R.; Kealey, G. P.; Wangler, R.; Clarke, W. R.; Cheng, H. F.; Printen, K. J. (Univ. Hosp., Univ. Iowa, Iowa City, IA 52242). *Am. J. Surg.* 131(2): 162-168; 1976.

The effect of gastric bypass on acid secretion in morbidly obese patients without acid peptic disease was investigated. Four studies were conducted: indwelling pH; standard analyses of gastric juice obtained from the excluded distal stomach; serum gastrin determinations obtained before and after a standard meal, pre- and postoperatively; and the incidence of stomal ulceration in patients who had undergone gastric bypass. Twelve of 28 patients had a low fasting pH before and after gastric bypass, and stomal ulceration developed in 2 of these patients. Histalog stimulation (50 mg) decreased the high fasting pH in seven patients, but had no effect on eight others. Gastric aspiration studies from the distal pouch show a decrease in gastric acid secretion in comparison to collections from the entire stomach, which had been obtained preoperatively. The pH remained well within the acid range. In the analysis of serum gastrin data, two separate quadratic curves were fitted to the pre- and postoperative data of eight patients. Statistical comparison of the curves yields an exact F of 4.63 with 3 and 5 degrees of freedom ($p<0.062$). Individual comparisons of the mean, linear, and quadratic components of the curves yielded: F(1,7); mean, 7.501 ($p<0.028$); linear, 2.211 ($p<0.179$); and quadratic, 8.810 ($p<0.020$). Overall comparison of preoperative to postoperative curves yielded an F that was nearly significant at the 5% level. The results indicate that acid secretion is reduced after gastric bypass, but that the acid, unbuffered by food in the excluded stomach, results in a lowered gastrin secretion after a meal.

4126 PSEUDOLYMPHOMA OF THE STOMACH. (Ger.) Struwe, O. (Medizinische Klinik der Stadtischen Kliniken, D-6100 Darmstadt, Grafenstr. 9, W. Germany). *Leber Magen Darm* 5(6):249-255; 1975.

Diagnostic, morphological, epidemiological, prognostic, therapeutic, and nosological aspects of pseudolymphoma of the stomach are reviewed in connection with four new cases. Predominantly pleomorphic pseudolymphoma was diagnosed in a 55-yr-old woman who underwent exploratory laparotomy for suspected gastric carcinoma. Predominantly monomorphic pseudolymphoma was found in a 30-yr-old man undergoing gastrectomy for major hematemesis and in a 29-yr-old man hospitalized for melena and hematemesis. Monomorphic pseudolymphoma was also found in a 79-yr-old woman presenting with unspecific abdominal complaints for 20 yr. Highly pronounced lymphocyte infiltration in follicular and diffuse pattern; sclerosis in the mucosa, submucosa, and muscularis propria; chronic inflammation and edema of the perigastric lymph nodes; and absence of pathological mitoses are the morphological and cytological characteristics of pseudolymphoma. The nonspecific symptoms (abdominal pain, emesis, anorexia, weight loss, anemia, hematemesis, and melena) suggest gastric ulcer or neoplasia. Therefore, pseudolymphoma can only be diagnosed by microscopic examination of the resected specimen and not by clinical, x-ray, or endoscopic examination. Surgery, with or without postoperative irradiation, is the therapy of choice. The prognosis is good with a 5-yr survival rate of 70-100%. Malignant transformation into gastric lymphoma is highly unlikely. Lymphatic hyperplasia of the gastric mucosa can be secondary to chronic gastric ulcer, or it may precede erosion and ulceration. Distinction between ulcerative pseudolymphoma and lymphatic hyperplasia is possible by microscopic examination of the fundus.

STOMACH

Peptic Ulcers

4177 PATTERNS OF GASTRIN COMPONENTS IN SERUM DURING FEEDING IN NORMAL SUBJECTS AND DUODENAL ULCER PATIENTS. (Eng.) Stadil, F.; Rehfeld, J. F.; Christiansen, L. A.; Malmstrom, J. (Rigshospitalet, 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 10(8):863-868; 1975.

The contribution of the different gastrin components to the gastrin response to a protein-rich meal was studied in 12 normal subjects and in 16 patients with duodenal ulcers. Pooled or individual samples of venous blood, drawn at intervals, were fractionated on Sephadex G 50 superfine columns of various lengths. Total gastrin immunoreactivity and concentrations of various components were measured radioimmunochemically. The changes in total serum concentration of immunoreactive gastrin were principally due to changes in component II (big gastrin) and III (little gastrin). The predominant pattern in both groups was an early increase in component III and a later and smaller increase in component II. Total gastrin response was largest in the patients with duodenal ulcer, and this was due mainly to component III. Fasting samples also showed a relatively higher concentration of component III in the ulcer patients. The results indicate that little gastrin is the more important component in the gastrin response to stimulation by food. Serum concentrations of total gastrin immunoreactivity are alike in normal subject and duodenal ulcer patients, but the findings indicate that increased levels of little gastrin may be characterisitic of duodenal ulcer disease. Since little gastrin is more potent than big gastrin, this would agree with the hypersecretion of acid in duodenal ulcer.

4178 SERUM GASTRIN AND SECRETIN LEVELS AFTER THE EXALTO-MANN-WILLIAMSON PROCEDURE. (Eng.) Tasse, D. P.; Kolts, B. E.; McGuigan, J. E.; Woodward, E. R.; Dragstedt, L. R. (College Medicine, Univ. Florida, Gainesville, FL 32610). *Arch. Surg.* 110(12):1482-1484; 1975.

To investigate the mechanism by which the Exalto-Mann-Williamson procedure consistently produces gastric acid hypersecretion and peptic ulceration in experimental animals, serum gastrin and secretin levels were determined in three dogs before and 3 weeks after undergoing the procedure. There was no significant change in serum gastrin. Serum secretin concentrations increased to 2.5 times the preoperative value (mean 66 pg/ml preoperatively and 165 pg/ml postoperatively), probably secondary to the enhanced secretion of gastric acid. The results of this experiment do not support the theory that alterations in circulating secretin or gastrin levels are responsible for the gastric acid hypersecretion following the Exalto-Mann-Williamson operation.

4179 CIMETIDINE IN DUODENAL ULCER: CONTROLLED TRIAL. (Eng.) Blackwood, W. S.; Pickard, R. G.; Maudgal, D. P.; Lawrence, D.; Northfield, T. C. (St. James's Hosp., London, England). *Lancet* 2(7978):174-176; 1976.

Preliminary results of a double-blind controlled clinical trial on the effects of cimetidine in patients with duodenal ulcers are reported. Repeat endoscopy in 21 patients completing 2 weeks of treatment with either cimetidine (1.6 g/day, p.o.) or placebo (lactose) revealed that the ulcers of 3 of the 9 patients on cimetidine and 1 of the 12 patients on placebo had healed. In 23 patients who completed 6 weeks of treatment, the ulcers in 9 of the 11 patients on cimetidine and in 3 of the 12 patients on placebo healed ($p<0.025$). The two cimetidine-treated patients whose ulcers had not healed at 6 weeks showed ulcer healing at endoscopy at 12 weeks. Of those who completed 12 weeks of treatment, all seven patients on cimetidine showed ulcer healing, but only three of the eight patients taking placebo showed healing ($p<0.05$). The ulcers of 5 of 10 patients of 1.6 g of cimetidine daily and of 7 of 13 patients on 0.8 g daily healed after 6 weeks of treatment, which was not a statistically significant difference. There were no significant changes from initial values for hemoglobin or WBC count in 27 patients who received cimetidine (0.8 or 1.6 g/day) or placebo for 6 weeks. Neutrophil counts, platelet counts, and alkaline phosphatase levels did not change significantly during treatment in any of the patients tested (25, 26, and 23 patients, resp.). No changes were observed on routine testing of the urine for glucose, blood, or albumin. Serum creatinine was significantly increased in the 13 patients who received 1.6 g/day of cimetidine for 6 weeks (85 ± 14 μM before treatment; 99 ± 12 μM after treatment), as was SGOT (22 ± 5.9 μM before; 31 ± 10.7 μM after treatment) in 12 patients on 1.6 g/day and SGPT (20 ± 6.8 μM before; 32 ± 17.3 μM after treatment) in 12 patients on the same dose. None of these changes was seen in the patients who received placebo or the lower dose of cimetidine. The results suggest that cimetidine at either dose is equally effective in achieving the healing of duodenal ulcers. The elevations in SGOT, SGPT, and serum creatinine emphasize the need to continue close clinical surveillance in patients taking cimetidine.

4180 NONASSOCIATION OF ADRENOCORTICOSTEROID THERAPY AND PEPTIC ULCER. (Eng.) Conn, H. O.; Blitzer, B. L. (Veterans Admin. Hosp., West Haven, CT). *N. Engl. J. Med.* 294(9):473-479; 1976.

A retrospective analysis of 42 studies and 5,331 patients of whom 2,985 were treated with adrenocorticosteroids was conducted to determine whether steroid therapy is associated with an increased prevalence of peptic ulcer. In 26 double blind investigations of 3,558 patients, peptic ulcers were reported in 1% of 1,491 controls and in 1.4% of the 2,067 steroid-treated patients. The rates of hemorrhage from peptic ulcer and of perforation of peptic ulcer were similar in the two groups. In 16 non-double blind investigations of 1,773 patients, peptic ulcer was more frequent in the steroid treated (1.1%) than in the control group (0.4%). When the double blind and non-double blind results were combined, the frequency of peptic ulcer was slightly higher in the steroid group. In the double blind study, the average daily dose of steroid or placebo was 19 mg of prednisone or its equivalent, and the mean duration of therapy was 97 days. Treatment with steroid for more than 30 days was associated with significantly more peptic ulcers than treatment for a month or less ($p<0.05$). An association was seen between peptic ulcers and the total dose of steroid administered. In patients who had received more than 1,000 mg of prednisone, peptic ulcer developed far more frequently than in those who were given smaller doses ($p<0.001$). Although patients who received more than 1,000 mg of placebo also had more ulcers than those who received smaller total doses of placebo ($p<0.001$), the rate of ulcer was higher in the large-dose steroid group (5.3%) than in the large dose placebo group (2.5%) ($p<0.05$). The data of the double blind studies suggest that the frequency of peptic ulcer is not increased by treatment with steroids. The non-double blind investigations show a slightly increased occurrence of peptic ulcer among the steroid treated patients.

4181 EFFECT OF FATTY ACIDS ON THE STIMULATED GASTRIC SECRETIONS IN MAN. (Eng.)

Schmidt-Wilcke, H. A.; Steinhagen, P.; Steinhagen, E.; Martini, G. A. (St. Franziskus-Hospital, II. Med. Abteilung, Hohenzollernring 72, D-44 Munster, W. Germany). *Digestion* 13(1/2):8-14; 1975.

The effect of C_8 to C_{18} fatty acids and their Na or K salts on the pentagastrin-stimulated gastric secretion in 28 healthy men and 12 radiologically-healed duodenal ulcer patients was examined. Pentagastrin (1.5 mg kg/hr in a NaCl solution, i.v.) was infused for seven 15-min periods. The gastric content was collected with a suction pump and divided into 15-min samples. After three 15-min periods, the test solutions or emulsions were administered intraduodenally by a single 5-min injection. Gastric secretion was reduced to 50% of the stimulated plateau following the administration of 10 ml of pure oleic acid. The duration of this inhibition exceeded 40 min. Three ml of oleic acid had the same inhibitory effect, but the duration was only 15 min. No effect was observed with doses less than 3 ml. However, 0.5 ml of oleic acid in a 20-ml saline emulsion produced the same effect as 3 ml of pure oleic acid. Sodium stearate and palmitate slightly reduced gastric secretion for about 40 min. Myristate had no effect. Caprinate and caprylate induced inhibitions with a mean intensity of 64 and 80%, resp., that of oleic acid with durations of about 30 min. The effects of laurate were similar to caprylate and caprinate, except for an observed secretory rebound. The author suggests these and other findings indicate that there may be various receptors in the duodenum that reduce acid flow and inhibit gastric emptying.

4182 GASTRIC GLYCOPROTEINS IN CHRONIC PEPTIC ULCER. (Eng.)

Roberts-Thomson, I. C.; Clarke, A. E.; Maritz, V. M.; Denborough, M. A. (Univ. Melbourne, Dept. Medicine, Melbourne, Australia). *Aust. N.Z. J. Med.* 5(6):507-514; 1975.

The output and concentration of gastric glycoproteins in gastric juice from patients with chronic duodenal (9), gastric ulcer (8), and from controls (10) were determined in the basal state and following pentagastrin (6 μg/kg) stimulation. The basal acid output (BAO) was significantly higher in patients with duodenal ulcer ($p<0.05$), and significantly lower in patients with gastric ulcer ($p<0.05$), than in controls. Maximal acid output (MAO) was significantly lower in patients with gastric ulcer ($p<0.005$) compared to controls. The patients with gastric ulcer had a significantly higher basal glycoprotein output ($p<0.05$), basal glycoprotein concentration ($p<0.02$), and stimulated glycoprotein concentration ($p<0.05$) than controls. There was no significant correlation between BAO and basal glycoprotein output in controls ($p>0.1$), patients with duodenal ulcer ($p>0.1$), or patients with gastric ulcer ($p>0.1$). No significant correlation between MAO and stimulated glycoprotein output in controls ($p>0.1$), patients with duodenal ulcer ($p>0.1$), or patients with gastric ulcer ($p>0.1$) was seen. The basal and stimulated glycoprotein output in gastric juice from patients with duodenal ulcer and from controls was independent of ABO blood group and secretor status. The principal carbohydrate components of gastric juice were galactose, N-acetylglucosamine, fucose, N-acetylgalactosamine, and sialic acid. The carbohydrate composition of the glycoproteins varied according to the BAO blood group and secretor status of the individual. The results show significant differences in either gastric glycoprotein output or concentration in patients with duodenal ulcers, compared with controls.

4183 CAUSES OF DEATH IN PATIENTS WITH GASTRIC ULCERS. (Eng.)

Lindskov, J.; Nielsen, J.; Amdrup, E.; Christiansen, P.; Fenger, C.; Jensen, H.-E.; Nielsen, S. A. D. (Kommunehospitalet, Copenhagen, Denmark). *Acta Chir. Scand.* 141(7):670-675; 1975.

The causes of death in 180 of 701 patients with gastric ulcers admitted to hospital during 1955-1964, and who died within 5 years from the time of admission, were determined. Causes of death were established at autopsy in 66% of the cases, and were derived from death certificates for the other 34%. Mortality was grouped by sex and age of the patients, and the causes of death were compared with the corresponding sex and age groups of the Copenhagen population. Mortality was significantly higher in the sample than in the general population, both for men and for women; within the 5-yr period, twice as many men and 2.5 times as many women died than expected. Observed mortality from gastric ulcer was 75 times higher in the nonsurgical group and 65 times higher in the surgical group. Gastric ulcer was the most significant cause of the observed higher mortality, but mortality from other diseases was also significantly higher than expected, both in men and in women. Mortality from suicide was significantly higher than expected in women. In men, pulmonary disease involved a significantly higher mortality than expected. If patients dying from cancer of the stomach within a 2-yr period are excluded, mortality from this disease was not significantly higher than expected. The study gives no support to the theory that benign gastric ulcers are prone to malignant degeneration.

4184 EARLY CLINICAL EXPERIENCE WITH METIAMIDE, A HISTAMINE H_2-RECEPTOR ANTAGONIST, IN PATIENTS WITH DUODENAL ULCER. (Eng.) Thompson, M. H.; Reed, J. D.; Dale, G.; Venables, C. W. (Royal Victoria Infirmary, Newcastle upon Tyne, NE1 4LP, England). *Am. J. Dig. Dis.* 20(12):1135-1141; 1975.

The clinical, endoscopic, and biochemical effects of metiamide, a histamine H_2-receptor antagonist, in therapeutic dosages were investigated in a 28-day open trial in 14 patients with duodenal ulcer. Eleven patients participated in two, single dose studies. Five patients took 200 mg metiamide four times daily, and six patients took 300 mg metiamide four times daily for 28 days. Clinical, hematological, and biochemical analyses were made at weekly intervals. Thirteen patients completed the study; 5 patients were symptomatic on day 0, 3 on day 7, 3 on day 14, and none on day 21. One patient's symptoms returned on day 28. Twelve patients underwent endoscopy. Ten had healed ulcers, and there was a reduction in ulcer size in the two patients where ulcers remained. The plasma creatinine rose from a mean of 0.96 to a mean of 1.19 for the group as a whole. There was a significant ($p>0.02$) rise in the SGOT and serum lactate dehydrogenase (LDH, $p>0.01$) in the group as a whole. The LDH rise was dose dependent ($p<0.05$ for the 300-mg dose and $p>0.07$ for the 200-mg dose), while the SGOT rise was not. There was a significant rise in the mean cardiothoracic ratio from 39.4 to 41.3 ($p<0.01$). The overall change in the fasting serum gastrin level was not significant. At a follow-up review, 1 month or more after the last drug treatment, five patients were symptomatic, four of whom had originally healed their ulcers. The results show that metiamide produces considerable symptomatic relief and a high rate of ulcer healing (72%) after 28 days of therapy.

4185 ULTRASTRUCTURE OF CELL MIGRATION THROUGH THE GASTRIC EPITHELIUM AND ITS RELATIONSHIP TO BACTERIA. (Eng.) Steer, H. W. (Southampton General Hosp., Southampton, England). *J. Clin. Pathol.* 28(8):639-646; 1975.

The migration of polymorphonuclear leukocytes and lymphocytes through the gastric mucosa was investigated by electron microscopy. Gastric biopsies were obtained from 8 patients at surgery for gastric ulceration, and tissue was obtained at gastroscopy from 39 patients with gastric ulceration. Polymorphonuclear leukocytes migrated from blood capillaries in the gastric mucosa through the gastric epithelium into the gastric lumen. They were frequently located at the periphery of the capillaries, and were often associated with strands of fibrin in the blood vessels. Small lymphocytes migrated from lymphoid follicles through the mucosal connective tissue, traversing the underlying basal lamina to enter the gastric epithelium. The lymphocytes lie between the epithelial cells and migrated through the epithelium into the gastric lumen. Bacteria were frequently related to the gastric epithelium. Some polymorphonuclear leukocytes that had migrated into the gastric lumen contained phagocytosed bacteria, which have similar ultrastructural characteristics to the bacteria that are related to the gastric epithelium. The bacteria in polymorphonuclear leukocytes were situated within membrane-bound vesicles, which are continuous with the generalized membrane system of the polymorphonuclear leukocyte. In addition to the bacterium, the vesicles contained electron dense granules (2 nm in diameter), which were found irregularly distributed in the cytoplasm of the polymorphonuclear leukocyte. This investigation, which did not include any immunological study, failed to reveal any obvious etiological factors for the lymphocytic migration.

4186 ON THE ENZYMATIC ACTIVITY OF BLOOD SERUM OF PATIENTS WITH PEPTIC ULCER DEPENDING ON THE METHOD OF SURGICAL TREATMENT. (Rus.) Romaniak, M. I.; Seniutovich, V. F.; Genyk, S. N.; Shevchuk, M. G. (Ivano-Frankovsk Medical Inst., Ivano-Frankovsk, USSR). *Klin. Khir.* (12):6-9; 1975.

SMALL INTESTINE

4218 ADENOCARCINOMA OF THE SMALL INTESTINE ARISING IN CROHN'S DISEASE: DEMONSTRATION OF A TUMOR-ASSOCIATED ANTIGEN IN INVASIVE AND INTRAEPITHELIAL COMPONENTS. (Eng.) Newman, R. D.; Bennett, S. J.; Pascal, R. R. (Greenwich Hosp., Greenwich, CT 06830). *Cancer* 36(6):2016-2019; 1975.

The case of a 67-yr-old man in whom an intestinal obstruction with coexisting regional enteritis and an invasive adenocarcinoma associated with an area of intra-epithelial neoplasia is reported. The surgical specimen consisted of approximately 45 cm of edematous, focally hemorrhagic, irregularly dilated, and constricted thickened ileum with serosal hemorrhage and areas of fibrinopurulent exudate. The cells of the adenocarcinoma and the intra-epithelial neoplasia contained a tumor-associated surface antigen capable of reacting with an antiserum prepared against a colonic carcinoma. The finding of a tumor-associated antigen on "atypical" epithelium in juxtaposition to the invasive carcinoma supports the suggestion that the focus of "atypia" is intra-epithelial neoplasia or preinvasive carcinoma.

4219 AMINO ACID PATTERN IN PLASMA BEFORE AND AFTER JEJUNO-ILEAL SHUNT OPERATION FOR OBESITY. (Eng.) Backman, L.; Hallberg, D.; Kallner, A. (Dept. Surgery, Karolinska Sjukhuset, Stockholm, Sweden). *Scand. J. Gastroenterol.* 10(8):811-816; 1975.

The amino acid pattern in plasma before and after jejuno-ileal shunt operation for obesity was investigated in a reference group (26), and in three groups of massive, obese subjects (9, 8, and 9, resp.). The three groups of obese subjects (A, B, and C, resp.) had different rates of weight loss and varying degrees of complications. Two different surgical methods were used: jejuno-ileostomy end-to-side and jejuno ileostomy end-to-end plus ileocecostomy end-to-side. There were no statistically significant differences between the three groups with regard to preoperative weight, weight after 52 weeks, or body height. All but two subjects in group B and all in group C had abnormal serum electrolytes or abnormal bilirubin, aspartate-aminotransferase, and alanine-aminotransferase postoperatively, and were hospitalized periodically.

There were no complications in group A. The concentrations of lysine, tyrosine, ½ cystine, and glutamic acids were higher in the obese subjects than in the reference group, while asparagine, glutamine, serine, and glycine were lower than in the reference group. During the postoperative period, the amino acid pattern changed significantly. Serine, glycine, and taurine increased, and valine, lysine, leucine, tryptophan, tyrosine, ½ cystine, and citrulline decreased. The amino acid pattern in the obese group with the longest postoperative observation time and a stable body weight differed significantly from that in the reference group only with regard to a low valine concentration and high concentration of taurine and glutamic acid. The results show that the obese subjects had a preoperative amino acid pattern that was significantly different from that in the reference group.

4220 SYMPTOMATIC HYPOGLYCAEMIA, LIVER GLYCOGEN DEPLETION AND CIRRHOSIS FOLLOWING JEJUNO-ILEAL BYPASS FOR GROSS OBESITY. (Eng.) Wilcox, R. G. (General Hosp., Nottingham, England). *Br. J. Surg.* 63(1)30-32; 1976.

A new complication following jejuno-ileal bypass for gross obesity is described. The patient, a 32-yr-old woman, suffered from hypoglycemic attacks that were associated with total depletion of liver glycogen together with a progressive micronodular cirrhosis. Increased dietary protein and calorie content (diet containing 3,000 calories and 100 g protein) relieved her symptoms and restored liver glycogen, but had no effect on the development of the cirrhosis over the next 12 months. It is concluded that the increased protein in this patient's diet contributed significantly to gluconeogenesis, as there was no identifiable improvement in glucose absorption.

Malabsorption

4252 BIRD-FANCIER'S LUNG AND JEJUNAL VILLOUS ATROPHY. (Eng.) Berrill, W. T.; Fitzpatrick, P. F.; Macleod, W. M.; Eade, O. E.; Hyde, I.; Wright, R. (Southampton Univ. Hosps., Southampton, England SO9 4PE). *Lancet* 2(7943):1006-1008; 1975.

Sixteen patients with bird-fancier's lung were screened for evidence of celiac disease by assessing their clinical features, RBC or serum folate levels, and serum for reticulin antibodies. Of nine patients with clinical or laboratory features that indicated the presence of malabsorption, two had total jejunal villous atrophy and three had subtotal villous atrophy; the case reports of these patients are presented. The two patients with total villous atrophy had no symptoms of malabsorption. Very low serum immunoglobulin A (IgA, <25 mg/dl) and high IgG (1,800 mg/dl) occurred in one patient with subtotal villous atrophy, and high IgG (>1,900 mg/dl) and high IgA (560 mg/dl) occurred in one patient with total villous atrophy; the Ig levels were normal in the other patients. Four of the five patients responded to a gluten-free diet, and in one, a repeat jejunal biopsy showed a normal mucosa. This suggests that these cases were true examples of gluten-sensitive enteropathy. The authors propose that the lung lesion is due to precipitins produced as a result of inhaled avian antigen, while the intestinal lesion is a gluten-sensitive enteropathy, both being associated because of a basic mucosal defect. Another reason for the association between villous atrophy and bird-fancier's lung may be that ingested avian antigen, absorbed through the gastrointestinal tract, may be involved in the pathogenesis of the lung lesion; this is a possibility in two patients in whom the lung lesion recurred without known contact with birds. Despite the low frequency of overt bird-fancier's lung in celiac disease, subclinical pulmonary disease might result from the intestinal absorption of avian antigen.

4253 ACUTE ABDOMINAL COMPLICATIONS OF COELIAC DISEASE. (Eng.) Connon, J. J.; McFarland, J.; Kelly, A.; Biggart, J. D.; McLoughlin, J. (Belfast City Hosp., Belfast, Northern Ireland). *Scand. J. Gastroenterol.* 10(8):843-846; 1975.

Two patients with rare complications of celiac disease are described. The first patient, a 63-yr-old woman who had been treated with a gluten-free diet for nearly a year, had obstruction of 12 cm of the jejunum, produced by multiple focal areas of active ulceration. The mucosa had a pattern varying from subtotal to severe partial villous atrophy. Further symptoms of intestinal obstruction and dysphagia led to similar findings in the esophagus. This was unusual, as there had been no esophageal lesions 3 months earlier, when the patient was examined radiologically and endoscopically. The second patient, a 52-yr-old man who had a 7-yr history of dermatitis herpetiformis, presented with right-sided abdominal pain and watery diarrhea, the result of a perforation of the proximal jejunum. The perforation was caused by a 6 x 3-cm ulcer that was secondary to the development of a localized malignant reticulum sarcoma. Partial villous atrophy associated with excess numbers of lymphocytes, plasma cells, and eosinophils in the lamina propria was also found. These cases indicate the importance of recognizing the occurrence of acute abdominal emergencies arising in the course of celiac disease.

4254 THE DISTRIBUTION AND ENTERIC LOSS OF ^{51}Cr-LABELLED LYMPHOCYTES IN NORMAL SUBJECTS AND IN PATIENTS WITH COELIAC DISEASE AND OTHER DISORDERS OF THE SMALL INTESTINE. (Eng.) Douglas, A. P.; Weetman, A. P.; Haggith, J. W. (Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, England). *Digestion* 14(1):29-43; 1976.

The migratory pattern of lymphocytes was studied in normal human subjects, in 13 patients with inflammatory bowel disease (9 with Crohn's disease, 3 with diarrhea not due to structural abnormality of the bowel, and 1 with acute tropical sprue), and in 8 patients with celiac disease. Peripherally harvested lymphocytes were labeled with ^{51}Cr and were then re-injected into the subjects. In nine normal subjects, fecal loss of lymphocytes was 0.20% over 5 days, whereas the fecal loss was 1.13% in five patients with untreated celiac disease; in Crohn's disease patients, it was 1.01%, and in five patients with intestinal lymphangiectasia, the loss was 0.61%. In the one patient with acute tropical sprue, enteric loss was 0.97%. In contrast to these findings, fecal loss was normal in the three celiac patients who were in remission on a gluten-free diet. An external counter revealed that the count rates steadily diminished in normal subjects, but increasing activity was recorded over the umbilicus, for 7 days after dose administration, in all disease

LIBRARY U.

tegories except of celiac disease patients who were ing treated. The loss of lymphocytes from the dy into the gut lumen demonstrates that the gut is lymphoid migratory compartment, which is open-ended d therefore of importance in assessing lymphocyte gration streams in the body. Prolonged excessive sses explain the immunological abnormalities found many of these conditions without implicating a imarily immune etiology for any of them. It is ggested that the development of malignancy in celiac sease, and possibly in Crohn's disease, may be nked to the continued loss of immunologically competent lymphocytes.

55 RELATIONSHIP OF LACTOSE INTOLERANCE TO MILK INTOLERANCE IN YOUNG CHILDREN. (Eng.)

rza, C.; Scrimshaw, N. S. (Dept. Nutrition and Food ience, Massachusetts Inst. Technology, Cambridge, MA 139). *Am. J. Clin. Nutr.* 29(2):192-196; 1976.

e prevalence of lactose intolerance was compared th the occurrence of intolerance to graded amounts milk (240, 360, and 480 ml) or equivalent amounts lactose (12, 18, and 24 g lactose in a peanut tter sandwich; PBL) in 69 Negro and in 30 Caucaan children. Of the Negro children studied, 11% those 4-5 yr old, 50% of those 6-7 yr, and 72% of ose 8-9 yr old were lactose intolerant, yet no ild was intolerant to 240 ml of milk. Of the ucasian children, 20% of those 8-9 yr were intolrant of lactose. The lactose-intolerant oup included 14 children, 9 of whom had posiive symptom responses to the PBL mixture or to milk, t had had no lactose tolerance test because consent uld not be obtained. Five of these children, who also d a blood glucose increase >20 mg/100 ml and marked mptoms after the standard lactose tolerance test se, demonstrated a blood glucose increase that was gnificantly lower ($p<0.025$) than that observed in ildren without symptoms. Twenty-one percent of the ctose-intolerant children had positive symptom reonses to 18 g of lactose in either whole milk or L. Among the 69 Negro children, one 9-yr-old child ported symptoms of intolerance at the 12 g level. significant differences were found between the lk intakes of Negro lactose-tolerant and lactosetolerant children, nor between the milk intakes 6- and 7-yr-old Negro and Caucasian children. wever, 8- to 9-yr-old Negro children drank signifiantly less milk than did 8- to 9-yr-old Caucasian ildren. The blood glucose response at 0, 20, and min after the ingestion of 2 g lactose/kg aximum 50 g) was unreliable as an indicator of individual's symptomatic response to lactose. mptomatic responses to greater amounts of milk not suggest that the frequency of primary lactose tolerance might be a reason for limiting existing lk programs for young children.

256 IgA DEFICIENCY IN ONE OF IDENTICAL TWINS.

(Eng.) Lewkonia, R. M.; Gairdner, D.; oe, W. F. (Hammersmith Hosp., London, England). *r. Med. J.* 1(6005):311-313; 1976.

he occurrence of selective immunoglobulin (Ig) A eficiency associated with a childhood illness resembling celiac disease in one of identical twin girls is reported. At age 6 months, both twins had an episode of gastroenteritis, which was less severe in the twin who was later found to be IgA-deficient (twin 1). Twin 1 continued to fail to thrive, and her symptoms were strongly suggestive of childhood celiac disease. This diagnosis was not sustained, however, because there was neither a clear clinical response to a gluten-free diet nor a relapse when gluten was reintroduced. Jejunal biopsies at age 13 revealed partial villous atrophy with round cell infiltration of the lamina propria and intra-epithelial lymphocytes in the mucosa of twin 1; the biopsy of twin 2 was normal. Immunoglobulin levels in both twins were first measured at age 23. A single radial immunodiffusion method showed that twin 2 was normal and that twin 1 had selective IgA deficiency, with a serum concentration of 0.02 g/l. Twin 1 probably had the deficiency since childhood, as her growth had remained retarded and she had recurrent sore throats. Dermatoglyphic ridge counts showed that the probability that the twins were monozygous was greater than 0.98. Identical serological results were obtained for 25 red cell antigens and 23 histocompatibility antigens. The authors suggest that the deficiency in twin 1 might be due to an inhibition of a class of B lymphocytes by specific suppressor T lymphocytes, perhaps induced by infection. The occurrence of IgA deficiency in one of identical twins suggests that the environment is important in either the initiation or the perpetuation of the deficiency in some people.

4257 DIARRHEA CAUSED BY A DEFICIT IN INTESTINAL DISACCHARIDES.

4263 CLEANSING OF THE COLON WITHOUT ENEMAS. (Eng.) Rosengren, J. E.; Aberg, T. (Dept. Radiology, Allmanna sjukhuset, S-214 01 Malmo, Sweden). *Radiologe* 15(11):421-426; 1975.

A nonenema method for the cleansing of the colon, which uses a magnesium sulfate salt solution (Salax) in combination with different oral laxatives (cascara sagrada, Dantron, bisacodyl) prior to roentgenographic examination, was developed. A total of 628 patients were prepared for colon examination: 365 received 30 mg cascarosides and 7.5 g magnesium sulfate, p.o. (224 were given castor oil and a water enema containing 150 mg cascarosides); 87 received magnesium sulfate alone; 87 received Salax and Dantron (50 mg each); and 89 received 3 bisacodyl pills of 5 mg each and 2 Salax powders containing 7.5 mg magnesium sulfate each. The presence or absence of feces was the sole method of evaluation. Only 27% of the patients prepared with castor oil and enemas were completely cleansed, while 66% of patients prepared with Salax and cascara were cleansed. Laxation with either Salax or cascara alone gave an unsatisfactory cleansing. Of the 224 patients who had been prepared with oral laxatives, 54 had been earlier prepared for colon examination with castor oil and enemas. Of these latter, 35 were better cleansed, 14 exhibited no more obvious difference, while 4 were less well cleansed with cascara-Salax. The time interval between ingestion of laxatives and colon examination was significant. The number of completely-cleansed patients prepared with morning and evening doses was greater than of those who received noon and evening doses. Side effects were reported by 24% of all patients, but were less marked after cascara-Salax than after castor oil and enemas. Older patients were less well cleansed than younger patients. The results show that cascara-Salax yields a better cleansing result than does the combination of castor oil and enemas.

4264 CARCINOEMBRYONIC ANTIGEN IN HEREDITARY ADENOMATOSIS OF THE COLON AND RECTUM. (Eng.) Alm, T.; Wahren, B. (St. Erik's Hosp., S-112 82 Stockholm, Sweden). *Scand. J. Gastroenterol.* 10(8):875-879; 1975.

The serum level of carcinoembryonic antigen (CEA) was determined in 130 individuals belonging to different families in which hereditary adenomatosis of the colon and rectum occurred. Fifty-six individuals were operated on with colectomy, 27 affected individuals were not operated on, and 47 were unaffected first degree relatives. Seventeen to 29% of the patients in each of these groups had moderately raised CEA serum levels compared to 25 unrelated healthy subjects. Since the serum values were low or only moderately raised (usually occurring between 0 and 10 ng/ml, and exceeding 20 ng/ml in only one affected patient without cancer) and occurred in all groups, the determination of serum levels cannot be generally used to indicate malignant transformation of adenomas. However, assays of the tissue CEA content in six histologically verified adenomas showed values similar to those of overt colonic carcinomas. This opens up possibilities of investigating the CEA activity in serum and tissues of chosen individuals with hereditary adenomatosis of the colon and rectum.

4265 CLINDAMYCIN-ASSOCIATED COLITIS: REVIEW OF THE CLINICAL SPECTRUM OF 47 CASES. (Eng.) Tedesco, F. J. (Univ. Miami Sch. Medicine, P.O. Box 875, Biscayne Annex, Miami, FL 33152). *Am. J. Dig. Dis.* 21(1):26-32; 1976.

Clindamycin-associated colitis was studied in 47 patients who received the antibiotic either p.o. (31), i.v. (8), or i.m. (1). Of the 47 patients, 13 (28%) had significant underlying illness: carcinoma (5), diabetes (4), and amyotrophic lateral sclerosis, leukemia, rheumatoid arthritis, and chronic renal failure (1 each). Forty of the patients were clinically well with complete proctoscopic resolution, at 4-16 months after the diagnosis of pseudomembranous colitis. Seven patients died. All of the patients were treated initially with bowel rest, lomotil, and i.v. fluids including electrolytes and albumin, if necessary. In this series, the most common clinical signs consisted of watery diarrhea, crampy abdominal pain, fever, and leukocytosis. These presenting symptoms were so severe in nine of the patients that surgical intervention was considered. Early proctoscopic examination prevented unnecessary exploratory laparotomy in these cases. It is concluded that patients who receive clindamycin should be observed carefully for the development of diarrhea. If it occurs, prompt proctoscopic examination should be performed; if colitis is found, the antibiotic should be discontinued immediately, and vigorous supportive therapy should be instituted.

4266 FAMILY STUDIES IN CANCER OF THE COLON AND RECTUM.

(Eng.) Lovett, E. (St. Mark's Hosp., London, England). *Br. J. Surg.* 63(1):13-18; 1976.

To examine the pattern of incidence of large bowel neoplasia in relatives, family histories were obtained from 209 patients undergoing treatment for cancer of the colon or rectum. Death certificates were obtained for parents and siblings who had died. The probability that the cause of death had been certified as cancer of the large bowel was calculated for each relative for whom a death certificate had been obtained. In all the groups of first degree relatives, there was a significant increase ($p<0.01$) in the number of deaths due to large bowel cancer compared with the number that could be expected in the general population. In deaths of both male and female relatives, carcinoma of the bowel was the most frequent malignancy. The increase in gastric carcinoma, although not so marked as the increase in large bowel carcinoma, was unexpected. Among the 209 index cases, 55 individuals had one or more adenomas present, as well as a carcinoma in the surgical specimen. Of these, 17 had a positive family history. The average age of diagnosis of large bowel cancer was 60.5 yr for men and 62.7 yr for women. Only eight patients were aged 40 or under when large bowel cancer was diagnosed; five of these had affected relatives. The presence of adenoma as well as carcinoma, a history of primary carcinoma, and an early age of onset of carcinoma are all associated with the likelihood that a patient has relatives who have also had large bowel cancer.

4267 COLONIC LYMPHANGIOMA.

(Eng.) Lawson, J. P.; Myerson, P. J.; Myerson, D. A. (Griffin Hosp., 130 Division St., Derby, CT 06418). *Gastrointest. Radiol.* 1(1):85-89; 1976.

Eight previously reported cases of colonic lymphangioma are reviewed, and three new cases are reported. Six of the eight previous cases were described as pedunculated, sessile, or polyploidal mucosal lesions. The first newly reported patient, a 50-yr-old woman, was found to have a multicystic, soft, gelatinous lesion measuring 1.5 x 1.5 x 2 cm in the region of the ileocecal valve. A stalk was noted, extending through the valve from the cecum. This is the only reported case in which the retrograde prolapse of a colonic lymphangioma into the terminal ileum was demonstrated radiologically. A 2-cm subepithelial lymphangioma was found in the hepatic flexure of the second patient, a 68-yr-old woman, who presented with hematochezia. A slightly lobulated, cyst-like lymphangioma occurred in the third patient, a 50-yr-old woman, who presented with intestinal cramps, nausea, vomiting, and diarrhea. Lymphangioma has occurred in eight of the 11 cases, and only one of the 11 patients was younger than 40 yr.

4268 PHARMACOLOGICAL CHARACTERISTICS OF THE GANGLIONIC AND AGANGLIONIC COLON IN HIRSCHSPRUNG'S DISEASE.

(Eng.) Penninckx, F.; Kerremans, R. (Univ. Clinics St. Raphael, Leuven, Belgium). *Life Sci.* 17(9):1387-1394; 1975.

The pharmacological characteristics of circular and longitudinal muscle strips from normal and aganglionic colon were investigated *in vitro* in 13 patients with Hirschsprung's disease. At least six strips were prepared from both the aganglionic and ganglionic colon in each patient. Drugs were added to the strips in either a single or cumulative dose. The sensitivity for acetylcholine (10^{-9}-10^{-3} M), noradrenalin (10^{-8}-10^{-4} M), and isoproterenol (10^{-8}-10^{-4} M) was normal in aganglionic tissue. Concentrations of bethanechol (10^{-8}-10^{-5} M), carbacholine (10^{-6}-10^{-5} M), metacholine (10^{-5}-10^{-4} M), and pilocarpine (10^{-4} M) induced stronger contractions in aganglionic strips than in normal strips. Concentrations of serotonin (10^{-7}-10^{-3} M) had an inhibitory effect in strips from both the proximal and distal segments. Concentrations of nicotine (10^{-5}-10^{-3} M), lobeline (10^{-7}-10^{-4} M), and dimethylphenylpiperazinium iodide (10^{-8}-10^{-4} M) did not induce a relaxation in aganglionic muscle strips. All strips contracted after histamine (10^{-5} M), but the contractions were stronger in aganglionic strips. It is concluded that there are no pharmacological arguments and no explanations for spasticity of the distal aganglionic colon, and that the type of denervation differs from that described elsewhere.

4269 IMMUNOGLOBULIN E IN RECTAL MUCOSA OF PATIENTS WITH PROCTITIS.

(Eng.) Heatley, R. V.; Calcraft, B. J.; Fifield, R.; Rhodes, J.; Whitehead, R. H.; Newcombe, R. G. (General Hosp., Nottingham, England). *Lancet* 2(7943):1010-1012; 1975.

Tissue and serum immunoglobulins (Ig) were measured by a direct immunofluorescence technique in 12 patients with chronic proctitis. Twelve samples were taken during the active disease, and six were taken during clinical remission, which was induced by topical treatment with disodium cromoglycate. (D.S.C.G.). These samples were compared with 10 samples from normal, control patients. Large numbers of brightly fluorescent IgE-producing cells were seen in specimens from patients, both in remission (median, 22; range, 4->50/high-power field) and during the active disease (median, 37; range, 8->50); the control values ranged between zero and one poorly fluorescent cells per high-power field. Specimens from the proctitis patients also contained many brightly fluorescent IgG- and IgM-producing cells, both in remission (median, 16; range, 0->50 IgG-producing cells and median, 4; range, 1-25 IgM-producing cells) and during active disease (median, 8; range, 0-35 IgG-producing cells and median, 10; range, 1-40 IgM-producing cells), in comparison to controls (median, 2; range, 0-5 IgG-producing cells and median, 4; range, 1-9 IgM-producing cells). The demonstration of large quantities of IgE in the rectal mucosa with a clinical response to D.S.C.G. supports the view that an immediate hypersensitivity reaction is involved in the pathogenesis of proctitis.

LARGE INTESTINE

Ulcerative Colitis

4292 THE CONSTIPATING EFFECT OF DIPHENOXYLATE (RETARDIN^{R}) IN ULCERATIVE COLITIS: A DOUBLE-BLIND CONTROLLED TRIAL. (Eng.) Engbaek, J.; Ersboll, J.; Faurby, V.; Binder, V.; Riis, P. (Gentofte Hosp., Univ. Copenhagen, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 10(7):695-698; 1975.

The ability of diphenoxylate to control diarrhea caused by ulcerative colitis was studied in 20 patients. In a double-blind, cross-over study, the patients received 5 mg of diphenoxylate three times daily for 14 days and placebo. The treatment sequence was randomized. The test variable for the ability of diphenoxylate to control diarrhea was the mean number of defecations per day. The criterion for inclusion of patients was the presence of four or more daily bowel movements; two patients did not complete the investigation. There was a significant difference ($p<0.01$) in the constipating effect between diphenoxylate and placebo; the average number of bowel movements was reduced by 0.7 per day during a 12-day trial and by 1.3 per day during a 6-day trial. Side effects were seen in 11 patients, 9 during treatment with diphenoxylate, 1 during treatment with diphenoxylate as well as placebo, and 1 during treatment with placebo alone. The side effects included drowsiness, pain, nausea, fatigue, dryness in the mouth, dizziness, headache, and itching. On the basis of the small reduction of defecation frequency and the incidence of side effects, diphenoxylate has no place in the routine treatment of ulcerative colitis.

4293 DELAYED-TYPE ALLERGY IN PATIENTS WITH ULCERATIVE COLITIS. II. ALLERGIC SKIN REACTIONS TO AUTOLOGOUS LEUKOCYTES AND THEIR EXTRACTS. (Eng.) Orlowska, J.; Tomecki, R. (Med. Center Postgraduate Education, Warsaw, Poland). *Mater. Med. Pol.* 7(3):204-209; 1975.

The allergic skin reactions to autologous leukocytes and their extracts were examined in 36 patients with ulcerative colitis. Tests were performed on 24 patients in complete remission and on 12 patients in moderate relapse. Leukocytes were isolated from peripheral blood, and a suspension of autologous leukocytes (0.2 ml) and the extract (0.2 ml) were injected intracutaneously on one forearm. At the same time, on the other forearm, injections of the patient's erythrocytes, autologous serum, and dextran were given. Results were considered positive for an allergic reaction if there was infiltration of the subcutaneous tissue, with or without reddening and with a diameter of 6 mm or more. Specimens were taken from sites of positive reactions. In 29 patients, there was a positive reaction in the form of infiltration at the site of leukocyte injection. There was erythema in some patients. No exudate or necrosis was observed. The reaction intensity peaked at 48-72 hr. An identical

LIBRARY U.

reaction occurred from the leukocytes extract in 28 patients. All 36 patients were positive to at least one, if not both, of the leukocytes and their extract. There were no reactions to control substances (erythrocytes, serum dextran). The macroscopic and histologic features of these reactions indicate that they are of cellular type.

4294 LIMITED FORM OF WEGENER'S GRANULOMATOSIS IN ULCERATIVE COLITIS. (Eng.) Kedziora, J. A.; Wolff, M.; Chang, J. (St. Vincent's Hosp., New York, NY). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1):127-133; 1975.

The limited form of Wegener's granulomatosis is described as a complication in two cases of chronic ulcerative colitis. The microscopic changes in these cases were similar. A chronic pleuritis and organizing pneumonitis of nonspecific type were noted in each case. There were areas of parenchymal necrosis, either sizable or smaller (not defined), with a multifocal distribution and with serpiginous borders. Elongated histiocytes aligned in a palisading pattern were found at the edge of the necrotic zones. Smaller arteries and veins frequently demonstrated a mural infiltration by round cells, focal areas of fibrinoid necrosis, and sectoral loss of elastic lamellae. Some of the involved vessels also showed noncaseating granulomata composed of epithelioid cells and Langhans' type giant cells. Similar granulomata were found, unassociated with vessels or necrotic foci. In one of the cases, a single granuloma was noted in the pleura, immediately adjacent to the lung parenchyma; neither vasculitis nor necrosis was seen in the pleura. Fair numbers of eosinophils within the pneumonitic areas were also seen, but none was found occupying vessel walls or granulomata. The other case showed rare eosinophils in two vein walls. Special stains for acid-fast bacilli and fungi were negative in both cases. The pathologic diagnosis was a limited form of Wegener's granulomatosis. The coexistence of ulcerative colitis and the limited form of Wegener's granulomatosis raises the question of a common etiologic basis, possibly of an immunologic defect. Awareness of such an association may shed further light on the etiology of both disorders.

PANCREAS

4298 EFFECT OF DIAZEPAM AND HYOSCINE BUTYLBROMIDE ON RESPONSE TO SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN IN MAN. (Eng.) Saunders, J. H. B.; Masoero, G.; Wormsley, K. G. (Dept. Therapeutics, Univ. Dundee, Dundee DD2 1UB, U.K.). *Gut* 17(5):351-353; 1976.

The effects of diazepam and hyoscine butylbromide on the pancreatic and biliary responses to parenteral secretin plus cholecystokinin were investigated in 10 patients undergoing studies for suspected pancreatic diseases. Secretin (1 clinical U/kg/hr) and cholecystokinin-pancreozymin (1 Ivy U/kg/hr) were administered for 45 min by continuous i.v. infusion in NaCl solution (0.15 M). On a different day, five subjects received 10 mg of diazepam, while the other five received 10 mg of diazepam plus 20 mg of hyoscine butylbromide, i.v., immediately preceding the hormone infusion. Diazepam alone did not significantly alter the total bicarbonate, trypsin, or bilirubin outputs in response to the hormones. The addition of hyoscine butylbromide did not significantly affect bicarbonate output, but the outputs of trypsin decreased in every subject. There was a significant delay in attaining peak rates of secretion of trypsin and of bilirubin compared with control after the injection of diazepam plus hyoscine butylbromide during both the first 15 and 30 min after the beginning of the infusion of the exogenous hormones. The use of these drugs during endoscopic cannulation of the pancreas will not significantly affect the measurement of pancreatic secretory capacity, provided that the collection is carried out for a sufficiently long period to compensate for a lag in the secretory response.

4299 STUDIES IN MECONIUM: DISACCHARIDASE ACTIVITIES IN MECONIUM FROM CYSTIC FIBROSIS PATIENTS AND CONTROLS. (Eng.) Antonowicz, I.; Ishida, S.; Shwachman, H. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *Pediatrics* 56(5, part 1):782-787; 1975.

ne enzymatic activity of disaccharidases (lactase,
ucrase, maltase, and palatinase) in meconium from
l healthy children and from 17 patients with cystic
ibrosis was investigated. Meconium with a positive
rotein test was presumed to come from a cystic
ibrosis infant and, in each case, the diagnosis was
onfirmed by a positive sweat test performed with
ne pilocarpine inotophoresis quantitative tech-
ique. All results were significant at $p<0.001$ for
isaccharidase activity and total protein. The total
roteins were significantly higher in meconium from
abies with cystic fibrosis than in meconium from
ealthy infants (139-601.5 mg/g meconium for cystic
ibrosis infants; 56-164.3 mg/g meconium for control
nfants). No activity of lactase, with one minor
xception, and palatinase could be detected in
econium from healthy infants, while the specific
ctivities of these enzymes in meconium from infants
ith cystic fibrosis were 13.1 μmol and 8.9 μmol/g
f protein/min, resp. The specific activity of
ucrase was 18 times higher and that of maltase,
.8 times higher in meconium from infants with cys-
ic fibrosis than in healthy infants. These studies
learly demonstrate a dramatic difference in the
isaccharidase activities of meconium from patients
ith cystic fibrosis in comparison to that from
ontrol subjects.

300 EFFECT OF INTRADUODENAL MAGNESIUM SULPHATE ON PANCREAS AND GALLBLADDER OF MAN. (Eng.)

aunders, J. H. B.; Thjodleifsson, B.; Wormsley,
. G. (Dept. Therapeutics, Univ. Dundee, Dundee
D2 1UB, Scotland). *Gut* 17(5):435-438; 1976.

o validate the use of magnesium sulphate as a
urgative in a test involving the measurement of
ecal pancreatic enzyme excretion, the pancreatic
nd biliary responses to an i.v. infusion of secretin
[1 clinical unit (CU)/kg/hr] plus cholecystokinin-
ancreozymin (CCK, 1 IU/kg/hr) in 18 patients were
ompared with the responses to one of three dose-
ates of magnesium sulphate infused into the duo-
enum. The effect of magnesium sulphate was also
studied during the coincident i.v. administration of
the hormones. $MgSO_4$ did not stimulate the secretion
of bicarbonate, and the mean bicarbonate output in
response to the exogenous hormones was not signifi-
cantly affected by any dose of $MgSO_4$ (40, 160, or
640 mM). At these doses, $MgSO_4$ evoked increasing
pancreatic secretion of enzymes. The response to
the infusion of 160 mM was significantly greater
($p<0.02$) than that of 40 mM; the output during the
infusion of 640 mM was greater than the response to
160 mM, but not statistically significant. In
response to the $MgSO_4$ infusion, the secretion of
bile pigment into the duodenum increased, both in
absolute terms and compared with the response to
exogenous hormones. The increase was significant
on increasing the dose rate from 40 to 160 mM
($p<0.05$). There was a statistically significant
increase in the cholecystokinetic response to the
exogenous hormones with 160 mM $MgSO_4$ ($p<0.05$). It
is concluded that the stimulant effect of $MgSO_4$ on
the pancreatic secretion of enzymes, together with
the absence of any interference with the pancreatic
response to exogenous stimulant hormones, makes $MgSO_4$ a satisfactory purgative for use in speeding the intestinal transit of pancreatic enzymes.

4301 PANCREATIC ASCITES: DIAGNOSTIC IMPORTANCE OF ASCITIC LIPASE. (Eng.)

Sileo, A. V.; Chawla, S. K.; LoPresti, P. A. (Catholic Medical Center of Brooklyn and Queens, Inc., Jamaica, NY). *Am. J. Dig. Dis.* 20(12):1110-1114; 1975.

Ten cases of pancreatic ascites are summarized, and special reference is made to conservative management and to the diagnostic value of ascitic lipase fluid determination. Nine patients were heavy alcohol drinkers. All patients presented with increasing abdominal girth associated with either diffuse abdominal discomfort or varying degrees of pain. Significant weight loss was a major symptom in five patients. Vomiting was a prominent symptom in four patients. There were significant degrees of ascites in all patients (mild, moderate, and severe). No patient demonstrated any stigmata of chronic liver disease. The diagnosis of pancreatic ascites was based on a marked elevation of ascitic fluid amylase (752-14,200 Somogyi-U), lipase (2.1-33.0 Cherry-Crandall U), and protein (3.2-15.4 g/100 ml). Serum amylase ranged between 150 and 3,000 Somogyi-U, and serum lipase was between 0.4 and 5.4 Cherry-Crandall U. In one case, serial ascitic fluid enzyme determinations revealed wide fluctuations in amylase levels, while the lipase remained elevated within a narrow range, suggesting that ascitic fluid lipase levels may be a more reliable diagnostic indicator of pancreatic ascites. At surgery, five cases showed evidence of subacute pancreatitis, and four cases had an associated pseudocyst of the pancreas. Conservative management, consisting of abdominal paracentesis with or without diuretics, resulted in complete recovery with no recurrence of symptoms or ascites in three cases.

4302 ISLET CELL CARCINOMA, PANCREATIC CHOLERA, AND VASOACTIVE INTESTINAL PEPTIDE. (Eng.)

Graham, D. Y.; Johnson, C. D.; Bentlif, P. S.; Kelsey, J. R. (Baylor Coll. Medicine, Texas Medical Center, Houston, TX 77025). *Ann. Intern. Med.* 83(6):782-785; 1975.

Three case reports are presented of patients with pancreatic cholera in whom raised blood or tissue vasoactive intestinal peptide (VIP) levels were present. The patients all exhibited profuse watery diarrhea, a nonbeta islet cell tumor, and the absence of gastric hypersecretion. Two patients, a 63-yr-old man and a 52-yr-old man, experienced prolonged remissions of diarrhea after tumor biopsy and after prednisone therapy. Fasting serum VIP levels ranged between 1,200 and 2,000 pg/ml in the first patient, with a level of 400,000 pg/g wet weight in the tumor biopsy. The first patient had elevated VIP levels persisting over several years. In the second patient, the fasting serum VIP level in the tumor biopsy was 1,500,000 pg/g and 600 pg/ml in a fasting plasma sample (normal controls<200). The third patient, a 42-yr-old woman, had elevated levels of both serum gastrin (655 pg/ml) and VIP

(2,700-4,100 pg/ml). It is unlikely that this patient's diarrhea was secondary to the Zollinger-Ellison syndrome, because of the absence of gastric hypersecretion. These cases further implicate VIP as the agent mediating the diarrhea in the pancreatic cholera syndrome.

4303 SIGNIFICANCE OF SERUM AMYLASE LEVEL IN EVALUATING PANCREATIC TRAUMA. (Eng.) Moretz, J. A., III; Campbell, D. P.; Parker, D. E.; Williams, G. R. (Univ. Oklahoma Health Sciences Center, Oklahoma City, OK). *Am. J. Surg.* 130(6): 739-741; 1975.

Attempts were made to correlate preoperative serum amylase levels in 51 patients who underwent exploratory laparotomy for blunt abdominal trauma with pancreatic injury. No statistically significant correlation was found between elevated serum amylase and pancreatic injury. The accuracy of the test improved somewhat with markedly abnormal serum amylase levels (>300 Somogyi U/100 ml), but even at these levels the correlation was not significant. It is concluded that there is no correlation between elevated serum amylase and pancreatic injury in blunt abdominal trauma. Decisions as to the advisability of operation in patients with such trauma should be based on other parameters.

PANCREAS

Pancreatitis

4312 PROSPECTIVE STUDY FOR THE PREVENTION OF PANCREATITIS FOLLOWING ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP). (Eng.) Koch, H.; Belohlavek, D.; Schaffner, O.; Tympner, F.; Rosch, W.; Demling, L. (Med. Univ.-Klinik, 852 Erlangen, Krankenhausstr. 12, W. Germany). *Endoscopy* 7(4):221-224; 1975.

Studies were undertaken to determine whether the administration of aprotinin or glucagon in addition to antibiotics would further decrease the number of patients developing pancreatitis following endoscopic retrograde cholangiopancreatography (ERCP). Fifty patients (group 1) were given tetracycline (1.5 g/day, p.o.) 2 days before ERCP, on the day of the examination, and 2 days after ERCP. Another 50 patients (group 2) were given the same treatment plus 500,000 U of aprotinin per infusion at the beginning of, and

1 hr after, ERCP. The third group (50 patients) received tetracycline plus 1 mg of glucagon per i.v. infusion immediately before cannulation, and 5 mg of glucagon per infusion starting 1 hr after ERCP and for the following 5 hr. All groups were seen to have an increase in leukocytes after 6 hr, which was statistically significant in the first and third groups ($p<0.01$ and $p<0.001$, resp.). Serum amylase increased significantly ($p<0.01$) after 6 hr in the third group. Lipase values increased significantly in all three groups after 1 hr; the increase in the second and third group, however, was more significant ($p<0.005$ and $p<0.01$, resp.) than in the first group. The third group had a significantly higher leukocyte rate ($p<0.001$) than the other two groups; there were no other significant differences between the groups. The incidence of pancreatitis in these 150 patients decreased to 1.7%, compared to an incidence of 13.5% after parenchymography of the pancreas reported in an earlier study and 5.1% after retrograde pancreatography without parenchyma visualization. The results suggest that neither glucagon nor aprotinin yields better prophylaxis against pancreatitis than the administration of antibiotics alone.

4313 PANCREATITIS AND THE PILL. (Eng.) Mungall, I. P. F.; Hague, R. V. (Royal Hosp., West St., Sheffield S1 3SR, U.K.). *Postgrad. Med. J.* 51(602):855-857; 1975.

The case of a 34-yr-old woman with acute pancreatitis who had been on a combined contraceptive pill (ethinyloestradiol and megestrol acetate) for 4 yr is presented. The patient experienced vomiting, recurrent upper abdominal pain, and chest pain. She had circulatory collapse, profound hypoxia, hypocalcemia (7.6 mg/100 ml), electrocardiogram changes ("T" wave inversion over the left standard and chest leads), and intravascular consumption coagulopathy complicating acute pancreatitis. Hyperlipidemia had previously been suggested as an etiological factor in cases of acute pancreatitis in women on the pill. However the lipid levels in this patient were normal. The authors recommend that acute pancreatitis be considered in any patient on the pill who develops abdominal pain, regardless of the serum lipid levels.

4314 EVALUATION OF THE GASTROCOLIC SPACE IN 100 CASES OF ACUTE PANCREATITIS. (Eng.) Moreno, G.; Rivera, H. H. (General Hosp. Mexico, SSA, Hershell 152 Anzures, Mexico 5, DF, Mexico). *Radiology* 118(3):535-538; 1976.

In 100 cases of acute pancreatitis, complete radiological studies of the chest and plain films of the abdomen were available, permitting an evaluation of the frequency of the radiological signs of this disease. Gastrocolic separation on the plain, supine, or upright film of the abdomen, observed with a nasogastric tube or with the aid of a barium swallow, was seen in 49 cases. This was usually found in obese patients with excess fat in the greater omentum. The colon cut-off sign was seen in 23 patients, and the sentinel loop in 21. Upward, forward, or downward displacement of the stomach, observed with a nasogastric tube or with the aid of barium, was seen in 22 patients, and generalized peritoneal reaction, observed in supine and upright plain films of the abdomen, was seen in 27 cases. Gastrocolic separation and colon cut-off were observed together in eight cases. Because of the high incidence of the gastrocolic space in acute pancreatitis, plain films are a useful aid in the diagnosis of this disease.

4315 SECRETIN DOSE-RESPONSE IN HEALTH AND CHRONIC PANCREATIC INFLAMMATORY DISEASE. (Eng.) Petersen, H.; Myren, J. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 10(8):851-861; 1975.

Proteolytic enzyme, bilirubin, and enzyme responses to secretin were studied in 12 healthy volunteers (HV), in 12 patients with a history of chronic pancreatic inflammatory disease of more than 5 yr (CP5), and in 9 patients with a history of 2 yr or less (CP2). Stepwise increasing doses of secretin (0.078, 0.233, 0.7, and 2.1 U/kg/hr) were administered to all subjects by gastroduodenal tube. The maximal bicarbonate response (Vmax) and the half maximal dose of secretin (Km) were calculated for each individual. Bicarbonate responses below that in HV were found in 10 of the CP5 and in 3 of the CP2. Vmax showed no superiority to the responses to the three largest doses of secretin in the diagnosis of bicarbonate secretory deficiency. In CP2, bicarbonate responses above that in HV were frequently found with the small doses of secretin. No evidence of hypersecretion was found. The findings suggest that the early stage of chronic pancreatic inflammatory disease may be associated with an increased sensitivity to secretin. Km was poorly reproducible and showed no diagnostic ability. Large doses of secretin stimulated the secretion of proteolytic enzymes, but the diagnostic efficiency was less than that for bicarbonate. The output of calcium varied markedly in CP2 and CP5. The bicarbonate/calcium ratio, however, was almost invariably lowered in these patients and showed diagnostic superiority to bicarbonate secretion. The findings suggest that more attention should be paid to calcium secretion in pancreatic function tests.

LIVER AND BILIARY TRACT

4325 THE RADIOLUCENT LIVER. (Eng.) Melhem, R. E. (American Univ. Medical Center, Beirut, Lebanon). *Pediatr. Radiol.* 4(3):153-156; 1976.

Five cases in which a diagnosis of fatty liver was made on the basis of an increased liver radiolucency on the plain film of the abdomen are reported. Two subjects had Reye's syndrome, one had glycogen storage disease, one had severe malnutrition, and one had severe hepatitis (probably viral). The age of the patients ranged from 3 to 8 months old. In one patient, the lateral border of the right kidney could be easily seen on the plain film. The radiolucent liver was more striking on the early films of the intravenous pyelogram in two patients. The radiological diagnosis was later confirmed by histopathologic examination in all patients. Increased liver radiolucency should be specifically looked for whenever severe hepatitis, toxins, severe malnutrition, Reye's syndrome, glycogen storage disease (especially type I), or cystic fibrosis are suspected clinically.

4326 LAPAROSCOPY AND PUNCTURE BIOPSY IN CHRONIC DIFFUSE INFLAMMATORY DISEASES OF THE LIVER. (Rus.) Mukhin, A. S.; Lebedev, S. P.; Severov, M. V. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Sov. Med.* (7):110-113; 1975.

The diagnostic value of laparoscopy and blind needle biopsy of the liver was studied in 100 cases of diffuse inflammatory hepatopathies. Full agreement was observed between the two techniques in 8 of 11 cases of normal laparoscopic picture, in 7 of 12 cases of fatty liver, in 3 of 3 cases of acute alcoholic hepatitis, in 13 of 20 cases of chronic hepatitis, and in 25 of 50 cases of liver cirrhosis. There was no agreement in four cases of cicatricial liver changes. The bioptic diagnosis was correct only in 52 of 100 cases. Active liver cirrhosis was demonstrated by biopsy in 19 of 20 cases of laparoscopically established active cirrhosis, and inactive cirrhosis in 23 of 30 laparoscopically diagnosed inactive cirrhosis. The biopsy sample was not evaluable in 20% of the cases. Correct diagnosis of the liver cirrhosis was possible in 80% of the cases by the combination of laparoscopy and biopsy. The findings indicate the high reliability of laparoscopic diagnosis in cicatricial liver, liver cirrhosis, and possibly in hepatic tumors and metastases, as well as in the evaluation of the activity of the hepatic process and of portal hypertension. Blind biopsy is indicated after laparoscopy for the follow-up of the activity of the hepatopathy. Laparoscopy should be combined ith biopsy in the diagnosis of diffuse hepatopathies, specially of chronic hepatitis, cirrhosis, and icatricial alterations.

327 HEMOBILIA COMPLICATING NEEDLE LIVER BIOPSY: A CASE REPORT WITH ARTERIOGRAPHIC DEMONTRATION.

(Eng.) Attiyeh, F. F.; McSweeney, J.; ortner, J. G. (Memorial Sloan-Kettering Cancer enter, 1275 York Ave., New York, NY 10021). *adiology* 118(3):559-560; 1976.

he case of a 16-yr-old boy with Hodgkin's disease ho developed massive hemobilia secondary to a eedle liver biopsy is reported. Six days after the rocedure, the patient experienced colicky epigastric nd right upper quadrant pain that radiated to the ack, icterus, hematemesis, and melena. Cholecystectomy and common bile duct drainage failed to control the hemobilia, which had been discovered at laparotomy. Selective angiography revealed an arteriobiliary fistula from a branch of the left hepatic artery. The right hepatic artery branched from the superior mesenteric artery. The left hepatic artery was ligated distal to the junction of the gastroduodenal artery, ending the hemobilia. It is concluded that hepatic artery ligation should be utilized in the treatment of this type of complication of needle biopsy; procedures such as suturing of the needle entry site or T-tube decompression may not be as effective, since they leave the patient in jeopardy of potentially fatal recurrent hemorrhages and the risks of further surgery.

4328 THE RELATIONSHIPS BETWEEN LIVER VOLUME AND THE DISPOSITION OF ANTIPYRINE AND INDOCYANINE GREEN BEFORE AND AFTER PHENOBARBITONE TREATMENT.

(Eng.) Branch, R. A.; Halliwell, M.; Jackson, L.; Roberts, C. J. C. (Dept. Medicine and Pharmacology, Univ. Bristol, Bristol BS8 ITD, U.K.). *Br. J. Pharmacol.* 55(2):263P; 1975.

The effect of p.o. administration of phenobarbitone (180 mg/day for three weeks) on liver volume and clearances of antipyrine and indocyanine green was investigated in 10 normal subjects. The antipyrine clearance of nine subjects correlated with liver volume ($r=0.69$, $p<0.05$), and the remaining subject had maximal induction of antipyrine at the beginning of the experiment. The initial clearances of indocyanine green of seven subjects approximated the expected liver blood flow and related to liver volume; the indocyanine green clearance in the other three subjects was lower than predicted by this relation. After phenobarbitone administration, there was no increase in liver volume. The clearance of antipyrine increased by 90 ± 14.1% ($p<0.001$). There was still a correlation between antipyrine clearance and liver volume ($r=0.86$, $p<0.01$), and there was no significant increase in indocyanine green clearance. It is suggested that in the absence of enzyme induction, variation in drug elimination is related to the total functional hepatic mass, and that phenobarbitone is able to increase the drug metabolizing capacity per unit of mass without causing an increase in total liver size.

4329 STIMULATION OF TRIACYLGLYCEROL SYNTHESIS BY Z PROTEIN IN RAT LIVER AND INTESTINAL MUCOSA.

(Eng.) O'Doherty, P. J. A.; Kuksis, A. (Dept. Biochemistry, Univ. Wisconsin, Madison, WI 53706). *FEBS Lett.* 60(2):256-258; 1975.

The role of the Z protein in the acylation of diacylglycerols to triacylglycerols was studied in microsomes of rat liver and intestinal mucosa. The addition of increasing amounts of Z protein (10-30 nmol) to the microsomes resulted in a 15-fold stimulation of triacylglycerol biosynthesis as measured by the incorporation of [1-^{14}C]palmitoyl coenzyme A (CoA) into triacylglycerols by the microsomes. With 30 nmol of Z protein, the incorporation of [1-^{14}C]palmitoyl CoA was 0.80 nmol/2 mg protein. With the addition of 10 mg of the 105,000 x *g* cytosol, the incorporation was 0.16 nmol/2 mg microsomal protein; with 20 mg of the cytosol, 0.35 nmol/2 mg; and with no addition, 0.05 nmol/2 mg. The addition of 20 or 40 nmol of albumin did not duplicate the action of the Z protein, suggesting that the stimulatory action is due to the Z protein and not to albumin, which is present in trace amounts in the cytosol. The addition of Z protein to intestinal microsomes in the same doses resulted in increases similar to those occurring in the liver microsomes (0.15-0.38 nmol/2 mg microsomal protein compared to 0.04 nmol in controls). The results suggest that the Z protein may be involved in the acylation of diacylglycerols to triacylglycerols in the microsomes of rat liver and intestinal mucosa.

4330 ANALYSIS OF HEPATIC-VENOUS ^{133}XENON CLEARANCE AFTER ADMINISTRATION OF THE GAS BY INHALATION.

(Ger.) Dietze, G.; Wicklmayr, M.; Czempiel, H.; Henftling, H. G.; Hepp, K. D.; Mehnert, H. (III Med. Abteilung, Stadt. Krankenhaus, Schwabing, D-8000 Munchen 40, Kolner Platz 1, Germany). *Klin. Wochenschr.* 53(13):639-640; 1975.

To determine the usefulness of hepatic-venous ^{133}Xe clearance for the calculation of hepatic blood flow, ^{133}Xe was measured at 10-sec intervals for 10 min in blood samples from the hepatic and portal veins of 12 normal subjects after they inhaled the gas. Clearance curves were plotted on a semilogarithmic scale. In contrast to findings obtained when ^{133}Xe was injected into the portal vein, a short multi-exponential component was obtained initially instead of a rapid component, and a mono-exponential terminal component F1 with a relatively large "wash out" constant K1, 0.22 ± 0.3/min, was obtained instead of a negligible terminal component. Arterial recirculation in the liver became negligible rapidly, suggesting that the mono-exponential terminal component F1 of the hepatic-venous clearance results from ^{133}Xe that has recirculated from the gastrointestinal tract. This was demonstrated by the mono-exponential decrease that occurred in the portal ^{133}Xe concentration; the time constant for this component, 0.34 ± 0.03/min, was not significantly higher than that for F1. Extrapolation of the terminal component F1 of hepatic-venous clearance of ^{133}Xe to the beginning of desaturation and subtraction from the multi-exponential initial component resulted in a mono-exponential component F2 with a mean wash out constant K2 of 1.24 ± 0.1/min. A hepatic blood flow of 91.8 ± 7.4 ml/100 g/min was calculated by using K2 and the formulas derived from Kety's principle, assuming that the distribution coefficient for the normal liver is 0.74. Further studies are necessary to determine the validity of the hepatic blood flow calculated by this simple graphic method, and to determine whether it is possible to obtain the same values with a scintillation detector applied externally rather than removing blood samples through catheters to measure the ^{133}Xe clearance.

4331 HYPERPARATHYROIDISM IN HEPATOBILIARY DISEASE IN INFANCY. (Eng.) Kobayashi, A.; Kawai, S.; Utsunomiya, T.; Ohbe, Y. (Natl. Children's Hosp., Taishido 3-35-31, Setagaya-ku, Tokyo 154, Japan). *Eur. J. Pediatr.* 121(1):5-13; 1975.

The tubular reabsorption of phosphate (TRP), calcium (TRCa), and magnesium (TRMg) were determined in 55 children (aged 2-45 months) with hepatobiliary disease to evaluate parathyroid function in this type of disease. In 33 cases of unrepaired biliary atresia, TRP was conspicuously reduced (mean=49.8%, standard deviation=15.1). In 10 cases of successfully repaired biliary atresia, the value was increased near the normal range (mean=80.7%, S.D.=8.1). In 10 infants with neonatal hepatitis, the value was variable in individual cases, but significantly lower than the normal (mean=47.6%, S.D.=19.9). TRCa was reduced in one-third of the patients with unrepaired biliary atresia and in one-fifth of the cases of neonatal hepatitis. The value was within the normal range in repaired biliary atresia. TRMg was decreased in both unrepaired and repaired biliary atresia and in neonatal hepatitis. The effect of i.v. calcium infusion (4.5 mg/kg/hr, 20 hr) on TRP, TRCa, and TRMg was evaluated in three patients with unrepaired biliary atresia. TRP was conspicuously enhanced after infusion. TRCa was decreased to a variable extent in three patients. TRMg was moderately increased in two children and greatly decreased in one. The results indicate that infants with hepatobiliary disease are in a state of secondary hyperthyroidism because of deficient or absent bile flow into the intestines.

4332 PYOGENIC LIVER ABSCESS SECONDARY TO ASYMPTOMATIC SIGMOID DIVERTICULITIS. (Eng.) Wallack, M. K.; Brown, A. S.; Austrian, R.; Fitts, W. T., Jr. (Univ. Pennsylvania, Philadelphia, PA 19174). *Ann. Surg.* 184(2):241-243; 1976.

The case of a 53-yr-old man with multiple pyogenic liver abscesses secondary to asymptomatic sigmoid diverticulitis is presented. The patient presented with fever, weakness, right-side abdominal pain, and an enlarged tender liver; a liver scan and celiac arteriogram showed spherical defects and areas of hypervascularity. At laparotomy, multiple abscesses containing *Enterobactor aerogenes* and *Pseudomonas aeruginosa* were found throughout the right lobe of the liver, although no obvious primary site of infection was found. There was a mass in the sigmoid colon, but no signs of acute inflammation were found around it. The mass was removed, and microscopic examination revealed diverticula and veins filled with pyogenic material. There was no history of diverticulitis preceding the sudden onset of the liver abscesses. The patient has done well for 2 yr following drainage of the abscesses and resection of the mass in the sigmoid. The authors propose that the liver abscesses came from the occult sigmoid diverticulitis.

4333 ALPHA$_1$-ANTITRYPSIN DEFICIENCY AND LIVER DISEASE IN CHILDREN: PHENOTYPES, MANIFESTATIONS, AND PROGNOSIS. (Eng.) Odievre, M.; Martin, J.-P.; Hadchouel, M.; Alagille, D.; Thaler, M. M. (Unite de recherche d'hepatologie infantile I.N.S.E.R.M. U 56, France). *Pediatrics* 57(2):226-232; 1976.

Clinical and histological findings and follow-up results in children with α_1-antitrypsin deficiency are reported. Among 424 children with liver disease, 20 had α_1-antitrypsin deficiency associated with protease inhibitor ZZ phenotype. The disorder manifested itself as cholestasis in early infancy in 19 children. Jaundice and pruritus cleared in 16 of these by 7 months of age, but hepatomegaly and laboratory evidence of mild hepatic dysfunction persisted in all. Biliary cirrhosis and portal hypertension eventually developed or was suspected in eight children, and hypoplasia of intrahepatic bile ducts was demonstrated in another four. Routine screening revealed intermediate α_1-antitrypsin deficiency in 16 other children with various types of liver disease. The phenotype in these patients was MZ, MS, or SZ. PAS-positive granules were present in liver of all patients with the ZZ phenotype and in none with other phenotypes. The findings indicate that manifestations and prognosis of this inherited liver disease are extremely variable.

4334 BENIGN LIVER CELL ADENOMA ASSOCIATED WITH USE OF ORAL CONTRACEPTIVE AGENTS. (Eng.) Baek, S.-M.; Sloane, C. E.; Futterman, S. C. (Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. and 100 St., New York, NY 10029). *Ann. Surg.* 183(3):239-242; 1976.

The case of a 31-yr-old woman who developed a hepatic adenoma and who had been taking oral contraceptives (Ortho Novum 2 mg) for 7 yr is reported. The patient presented with right upper quadrant pain associated with nausea, vomiting, and fever. A well circumscribed, nonencapsulated tumor (18 x 16 x 12 cm) was found in the right lobe of the liver that extended into the pelvis. The tumor was highly vascular with blood vessels on the surface. Following right hepatic lobectomy and cholecystectomy, the patient had an uneventful recovery. The increasing number of reports of benign hepatic adenoma arising in the livers of young women taking oral contraceptives strongly suggests an association between the contraceptives and benign hepatic adenoma.

LIBRARY U.

335 HEPATIC CHANGES IN YOUNG WOMEN INGESTING CONTRACEPTIVE STEROIDS: HEPATIC HEMOR-HAGE AND PRIMARY HEPATIC TUMORS. (Eng.) Mays, E. .; Christopherson, W. M.; Mahr, M. M.; Williams, H. . (Albert B. Chandler Medical Center, Univ. Ken-ucky, Lexington, KY 40507). *JAMA* 235(7):730-732; 976.

he cases of 13 women (22-47 yr) who developed rimary hepatic tumors after taking oral contracep-ives for 0.5-8 yr are described. The contracep-ives included norethynodrel, norethindrone, ethy-nodiol diacetate, norethindrone, and norgestrel, all ombined with mestranol, and norgestrel plus ethinyl stradiol. Nine tumors were benign. Of the four atients with malignant hepatocellular carcinoma, nly one was alive 2 months after a right lobectomy; n two cases the tumor was nonresectable, and in the ther case, the patient died during resection. The alignant tumors had irregular nests of hepatocytes rowing randomly, without cord organization. The uclei were irregular and hyperchromatic, and venous invasion was evident in these well-differentiated arcinomas. Six tumors (5 focal nodular hyperplas-ias, 1 carcinoma), caused massive hemoperitoneum averaging 2,500 ml in four patients. Eight benign tumors were successfully resected, and the patients were alive 8 months to 6 yr after the resection. A possible link between steroid contraceptives and hepatic tumors was especially likely in the ninth patient with a benign tumor. After taking contracep-tives for 5 yr, the patient required lobectomy for a ruptured tumor; after continuing the use of the drug for a further 6 yr, a similar benign tumor (which was not resected) developed.

4336 HEPATOMA OCCURRING TWO DECADES AFTER HEPATIC IRRADIATION. (Eng.) Moore, T. A.; Ferrante, W. A.; Crowson, T. D. (Ochsner Medical Center, New Orleans, LA 70121). *Gastroenterology* 71(1):128-132; 1976.

A case of hepatocellular carcinoma that occurred two decades after radiotherapy for presumed hepatic hemangioma is presented. At 12 yr, the patient was diagnosed as having hepatic hemangioma and received 1,350 rads of orthovoltage irradiation to the liver by an anterior port for 6 weeks. Seven months later, the patient received 1,200 rads through a right lateral port for 8 days (total dose 2,500 rads). After 19 yr, the patient noticed a right upper abdominal mass. With the exceptions of episodic right upper quadrant pain and mass, the patient was virtually asymptomatic. Abnormal laboratory findings included alkaline phosphatase, SGOT, and BSP retention levels. A colloidal gold liver scan revealed a grossly enlarged liver with hypertrophy of the left lobe and a large area of decreased isotope uptake in the lower two-thirds of the right lobe. At exploratory surgery, a large tumor of the right hepatic lobe and part of the left hepatic lobe was found. The tumor was thought to be resectable, and an extended right hepatectomy with cholecystectomy was performed. Several months later, the patient developed serum hepatitis and had abnormal liver function tests and liver scans. Three yr later, a percutaneous liver biopsy revealed recurrent hepatoma, and 5-fluorouracil therapy (300 mg/day for 10 days, intraperitoneally) was begun. At 1-month follow-up, liver function studies had returned to normal levels, and the hepatic nodules had returned to normal size. Less than 1 yr later, hepatic enlargement again occurred. The patient died 1 yr later, 26 yr after radiation therapy. This may represent the first case of hepatoma associated with therapeutic hepatic radiation, and it emphasizes the long-term effects of radiation on the human liver.

4337 RADIORESPIROMETRIC STUDY OF CARBOHYDRATE METABOLISM IN CHILDHOOD LIVER DISEASE. (Eng.) DaCosta, H.; Shreeve, W. W.; Merchant, S. (Veterans Admin. Hosp., Northport, NY). *J. Nucl. Med.* 17(3):218-219; 1976.

Studies were undertaken to determine whether any abnormalities in the metabolism of ^{14}C-labeled galactose or glucose occurred in 27 children with Indian childhood cirrhosis or in 14 patients with idiopathic infiltration in comparison with 9 controls. Each subject received ^{14}C-1-galactose (0.25 g galactose/kg, p.o.) on the first day and ^{14}C-U-glucose (0.5 g glucose/kg) 2 days later. The exhaled $^{14}CO_2$ was determined. There was a 10-fold increase over normal peak values for ^{14}C-glucose. Galactose catabolism was diminished 30-fold in cirrhotic patients during the initial 4-hr observation period. Children with fatty hepatic infiltration attained normal peak values, albeit after a longer time interval. The marked reduction in oxidation of ^{14}C-galactose to $^{14}CO_2$ in Indian childhood cirrhosis could relate to the marked diminution of blood flow and extensive hepatic fibrosis characteristic of the disease. The results suggest the feasibility of this radiorespirometric technique for monitoring patients with liver disease.

4338 FURTHER CLINICAL STUDIES WITH INTRAHEPATIC ARTERIAL INFUSION WITH 5-FLUOROURACIL. (Eng.) Ansfield, F. J.; Ramirez, G.; Davis, H. L., Jr.; Wirtanen, G. W.; Johnson, R. O.; Bryan, G. T.; Manalo, F. B.; Borden, E. C.; Davis, T. E.; Esmaili, M. (Univ. Wisconsin Medical Sch., Madison, WI). *Cancer* 36(6):2413-2417; 1975.

A clinical study of the treatment of liver metastasis with intrahepatic arterial infusion of 5-fluorouracil (5-FU) was made in 419 patients. Three-fourths of the patients had received 5-FU, i.v., before being switched to the infusion method. In most cases, the metastases were of colorectal primaries. The remaining patients did not receive 5-FU, i.v., because the primary metastasis was not responsive to 5-FU, the metastasis was too far advanced for an i.v. trial, or the liver metastasis was associated with jaundice from parenchymal liver involvement and was too poor a risk for i.v. loading. Toxic reactions included nausea and vomiting (33), diarrhea (62), abdominal pain (23), stomatitis (26), leukopenia (10), and thrombocytopenia (1). Morbidity resulting from intrahepatic artery infusion was caused by catheter displacement (45) catheter cracking or leaking (21), infection at the site of percutaneous catheter entry (16), upper gastrointestinal bleeding (11), and other causes (16). Of the 419 patients, 293 were selected for study. Of these, 161 (55%) improved, with a mean survival of 11.6 months. The mean survival for those unimproved was 5.6 months. The mean survival of those who improved is far greater than double the mean survival of patients not treated with chemotherapy. The authors conclude that arterial infusion of 5-FU remains an important therapeutic consideration until a more effective therapy is developed for patients with liver metastasis, especially of colorectal origin.

4339 HYPERALANINEMIA, HYPERPYRUVICEMIA AND LACTIC ACIDOSIS DUE TO PYRUVATE CARBOXYLASE DEFICIENCY OF THE LIVER; TREATMENT WITH THIAMINE AND LIPOIC ACID. (Eng.) Maesaka, H.; Komiya, K.; Misugi, K.; Tada, K. (Kanagawa Children's Medical Center, Mutsukawa, 2-138-4 Minami-ku, Yokohama, Japan). *Eur. J. Pediatr.* 122(2):159-168; 1976.

The case reports of a 16-month-old female infant with severe mental and motor retardation, clinically diagnosed as Leigh's encephalomyelopathy, and her 2.5-yr-old retarded sister are presented. Laboratory studies of the infant showed elevated serum nonesterified fatty acid (1,170 μEq/l), varying blood glucose level (64-84 mg/dl), a pH of 7.475, pO_2 112 mm Hg, pCO_2 10.8 mm Hg, and a base excess of 14 mEq/l. Cerebrospinal fluid glucose was low (45-53 mg/dl), and there was a significant increase in alanine. Blood lactate and cerebrospinal fluid lactate were 56.4 and 49 mg/dl, resp. Urinary lactate excretion was increased (0.37 versus 0.04 mg/mg creatinine for normals), and pyruvate excretion was increased (0.14; normal, 0.03 mg/mg creatinine). In the older sister, the electromyogram showed complex NMU, suggesting a neurogenic disturbance. Blood lactate was normal, but at age 4, repeated studies revealed that the blood lactate was 32 mg/dl and blood pyruvate was 3.1 mg/dl. These findings suggest an inborn error of metabolism in gluconeogenesis. Both sisters clinically and biochemically showed improvement with treatment of thiamine HeL and lipoic acid. It is concluded that the effect of thiamine and lipoic acid is due to a shunt mechanism for pyruvate disposal via pyruvate dehydrogenase, in which both materials act as cofactors.

4340 EFFECT OF CHENODEOXYCHOLIC ACID ADMINISTRATION ON BILE ACID AND CHOLESTEROL SYNTHESIS IN MAN. (Eng.) Halloran, L. G.; Schwartz, C. C.; Vlahcevic, Z. R.; Gregory, D. H.; Swell, L. (Medical Coll. Virginia, Richmond, VA). *Surg. Forum* 26:439-442; 1975.

The effect of exogenous chenodeoxycholic acid (CDCA) on cholic and CDCA synthesis and on cholesterol and phospholipid secretion was studied in three men undergoing elective, common bile duct surgery for cholesterol choledocholithiasis. Four hr after the start of a 9-hr constant i.v. infusion of DL-[5-^{3}H] mevalonic acid (15 μCi/hr), 300 mg of CDCA with 8 μCi [^{14}C]CDCA was administered via an intraduodenal Silastic catheter. Total bile acid synthesis averaged 2.69 μM/min, and fell to 1.96 μM/min ($p<0.001$) within 2 hr of CDCA administration. Primary bile acid synthesis decreased, averaging 32% for cholic acid and 29% for CDCA. Bile acid synthesis moved toward the baseline by the 14th hr when exogenous [^{14}C]CDCA disappeared from the bile. Biliary cholesterol and phospholipid secretion were not significantly altered by the exogenous CDCA. Within 90 min, there was a marked decrease of ^{3}H in both bile acids, indicating a decrease in the activity of cholesterol 7α-hydroxylase; however, ^{3}H activity increased in both bile acids, suggesting suppression at an additional feedback site, HMG-CoA reductase.

4341 HEPATIC MORPHOLOGY AND BILE ACID COMPOSITION OF BILE AND URINE DURING CHENODEOXYCHOLIC ACID THERAPY FOR RADIOLUCENT GALLSTONES. (Eng.) Pedersen, L.; Bremmelgaard, A. (Medicinsk afdeling I, Aalborg Sygehus, afsnit NORD, 9000 Aalborg, Denmark). *Scand. J. Gastroenterol.* 11(4):385-389; 1976.

The safety of using chenodeoxycholic acid (CDCA) for the treatment of radiolucent gallstones was investigated in nine patients receiving CDCA (500-750 mg/day for 3-14 months). In four patients, pretreatment percutaneous liver biopsy specimens were available for comparison; no sign of hepatic cellular necrosis or bile duct proliferation was seen. In two patients, hepatic steatosis was reduced, and in one patient, moderate portal tract inflammation decreased during therapy. Mean values of alkaline phosphatases, alanine aminotransferases, prothrombin, and serum lipids remained unchanged and did not exceed normal limits. In five patients, the urinary bile acid profile was examined during therapy. CDCA constituted 27-50%, lithocholic acid 25-63%, and ursodeoxycholic acid 0-13% of total bile acids in the urine. The renal excretion of total bile acids was estimated to be less than 2 mg/day in each patient. Between 86 and 100% of the bile acids in the urine were sulfated. These studies indicate that daily doses of 500-750 mg of CDCA do not harm the liver.

4342 STUDIES IN CHOLESTASIS OF PREGNANCY: III. FATTY ACID COMPOSITION OF SERUM PHOSPHOGLYCERIDES. (Eng.) Johnson, P.; Olegard, R.; Samsioe, G.; Gustafson, A. (Sahlgren's Hosp., Univ. Goteborg, Goteborg, Sweden). *Acta Obstet. Gynecol. Scand.* 54(3):241-246, 1975.

The influence of cholestasis of pregnancy (CP) on liver lipid synthesis, reflected by the composition of serum phosphoglycerides, was studied in 28 pregnant women in the last trimester by gas-liquid-chromatography. All patients complained of pruritus and had immunologically detectable lipoprotein-X (LP-X) in their serum. Twenty women with uncomplicated pregnancies served as controls. In lecithin, low palmitic acid (16:0) and high oleic acid (18:1 [n-9]) were found, which appear to be characteristic

LIBRARY U.

for CP. The increased oleic acid suggests an enhanced liver lecithin synthesis through the cytidinediphosphate diglyceride pathway. The concentrations of lecithin were measured from the gas-liquid-chromatograms using an added internal standard fatty acid, which gave a linear relation to direct determination of lecithin. For further studies of the influences of cholestasis of pregnancy on the relative fatty acid composition, lecithin was chosen because differences between lecithin (phosphatidyl choline) and phosphoglycerides (GPL) were found, evidently due to mutual variations among the three components in GPL (lecithin, cephalin, and lysolecithin).

4343 LP-X IN CHOLESTASIS. (Eng.) Tanno, H.; Fay, O.; Palazzi, J.; Pedrana, R.; Yager, E.; Roncoroni, M. (Unidad de Higado, Sanatorio Parque and Instituto de Estudios Bioquimicos, Orono 860, Rosario, Argentina). *Acta Hepatogastroenterol.* 22(5):289-291; 1975.

The sera of 62 patients with intra- and extrahepatic biliary obstruction of different etiologies were tested for the presence of lipoprotein-X (Lp-X). Lp-X was detected in 19 of 20 patients with cholestasis by tumor obstruction; in 14 of 16 patients with cholestasis by lithiasis, in 5 of 6 patients with cholestatic hepatitis, in 2 of 4 patients with cirrhosis, in 3 patients with benign, recurrent, intrahepatic cholestasis, and in 1 of 2 patients with recurrent jaundice of pregnancy. It was not detected in seven patients with noncholestatic hepatitis or in one patient with the Dubin-Johnson syndrome. Lp-X disappeared in the sera of four patients with large bile duct obstruction due to tumor 2 weeks after the tumors were removed. Although the presence of Lp-X does not help in the differential diagnosis of extra- and intrahepatic biliary obstruction, its presence does help to confirm the existence of cholestasis.

4344 SERUM IMMUNOGLOBULIN LEVELS IN PRIMARY LIVER CANCER: RELATIONSHIP TO UNDERLYING CIRRHOSIS AND HEPATITIS-B (SURFACE) ANTIGENAEMIA. (Eng.) Ipp, T.; Macnab, G. M.; Geddes, E. W.; Kew, M. C. (South African Inst. Medical Res., Johannesburg, South Africa). *Br. J. Cancer* 32(4):509-511; 1975.

Serum immunoglobulin (Ig) IgG, IgM, and IgA levels were measured by the single radial diffusion method in 107 South African patients with primary hepatocellular cancer (PHC) and 112 healthy blood donors. The mean serum IgG and IgM concentrations were significantly higher ($p<0.001$) in the PHC patients. In 20 patients in whom PHC was associated with cirrhosis, the serum IgG level was greater ($p<0.02$) than in those without cirrhosis. However, the mean serum IgG concentration in the non-cirrhotic cancer patients was still significantly higher than the control value ($p<0.001$). Thus, while cirrhosis may contribute to the raised IgG levels in PHC, other factors must also be involved. There was no difference in the serum immunoglobulin concentrations in the 63 PHC patients with hepatitis B antigenemia and in those without antigenemia.

4345 PRIMARY CYTOMEGALOVIRUS INFECTION AND LIVER INVOLVEMENT IN EARLY INFANCY. (Eng.) Chiba, S.; Hori, S.; Kawamura, N.; Nakao, T. (Sapporo Medical Coll., Sapporo, Japan). *Tohoku J. Exp. Med.* 117:143-151; 1975.

Primary cytomegalovirus (CMV) infection and liver involvement in early infancy were investigated in 237 patients under 1 yr of age to clarify the etiologic significance of primary infection with CMV in infancy. Fresh urine and mouth swab specimens were inoculated into tubes of human embryonic lung fibroblasts (HEL). The CMV was identified characteristic cytopathic effect (CPE) and by failure to demonstrate CPE in nonhuman and epithelial cells. SGOT and SGPT tests were carried out simultaneously with virus isolation in 205 and 207 infants, resp. The CMV was isolated from 29 of 87 infants and in 28 of 66 infants with liver involvement. The rates of virus isolation from the infants with normal GOT and GPT values were 14% and 13%, resp. The differences in virus isolation rates between normal and abnormal groups were statistically significant ($p<0.05$). They were more pronounced in infants under 3 months of age, and five to seven times higher in the infants with liver involvement. Tests of SGOT and SGPT were carried out on 250 and 244 infants simultaneously with complement-fixing antibody (CF) determination. There was no significant difference between the group with liver involvement and the control group, although CF antibody against CMV was detected slightly more often in the infants with liver involvement than in those without. The results indicate the significant correlation between virus recovery and liver abnormality, especially in very early infancy. The correlation between CF antibody and liver involvement was not significant, probably because of the influence by maternal antibody.

4346 CAUSES OF DEATH IN FULMINANT HEPATIC FAILURE AND RELATIONSHIP TO QUANTITATIVE HISTOLOGICAL ASSESSMENT OF PARENCHYMAL DAMAGE. (Eng.) Gazzard, B. G.; Portmann, B.; Murray-Lyon, I. M.; Williams, R. (King's Coll. Hosp., London S.E.5, England). *Q. J. Med.* 31(3):615-626; 1975.

The clinical course and causes of death in 132 consecutive patients with fulminant hepatic failure and grade III or IV encephalopathy were reviewed. One hundred and five patients died, and an autopsy was performed in 96 of them. In 36 patients, there was cerebral edema, and the mean age of this group (30 ± S.D. 15 yr) was significantly younger ($p<0.05$) than the other fatal cases (40 ± S.D. 16 yr). In 28 patients, death was attributed to major hemorrhage, which originated in the gastrointestinal tract in 25. The prothrombin time ratio was not significantly greater in patients with major bleeding than in those without, but they did have a significantly lower platelet count (mean, 53,000 mm^3 ± S.D. 22,000 and 91,000 mm^3 ± S.D. 53,000, resp.; $p<0.05$). Sepsis contributed to death in 12 patients. In 25 patients, massive hepatic necrosis only was found at autopsy, and death was considered to be due solely to hepatic failure. The degree of hepatocyte loss was assessed in 80 fatal cases by a histological morphometric technique on a needle specimen of liver taken immediately postmortem. The proportion of the liver volume occupied by hepatocytes (hepatocyte volume fraction, HVF) was greatly reduced in all patients ($<12\%$, normal 85 ± S.D. 5%), but the mean value was significantly higher in the patients dying with sepsis, cerebral edema, or hemorrhage than in the group in whom death was attributed solely to hepatic failure ($p<0.01$ and $p<0.05$, resp.). There were 10 patients in whom liver function was improving at the time of death; death was attributed to cerebral edema (9) or hemorrhage (1). It is suggested that many patients presently dying from fulminant hepatic failure may be expected to survive, once more effective therapy is available for the complications of the illness.

4347 CONGENITAL HEPATIC FIBROSIS. (Eng.)

Hodgson, H. J. F.; Davies, D. R.; Thompson, R. P. H. (St. Thomas' Hosp., London SE1, England). *J. Clin. Pathol.* 29(1):11-16; 1976.

The cases of four male patients with congenital hepatic fibrosis are reported. In all cases, the diagnosis was confirmed by the presence of various types of renal disease and by a liver with a normal lobular architecture that was broken up by broad fibrous bands containing dilated and/or excess numbers of bile ducts and by reduced numbers of portal veins. In three patients, the age of onset of the disease was unusually late; patient 1 presented with his first hematemesis at age 36; patient 3 was not correctly diagnosed until age 52, having presented with jaundice and abdominal pain at 37; and patient 4 was not correctly diagnosed until age 32, having presented at 24 yr with epigastric pain due to duodenal ulcer. Patient 3 was diagnosed at age 15 after experiencing hematemesis. The renal involvement was minimal in patients 1 and 3 and more marked in patients 2 and 4. Patient 2 probably had juvenile polycystic disease. Patient 3 had medullary sponge kidney. The kidneys of the first patient showed fetal lobulation, and there was some interstitial fibrosis and many cysts around the corticomedullary junction. The combination of cholangitis and large numbers of bile ducts led to the misdiagnosis of biliary cirrhosis in patient 1. The extrahepatic biliary tree was normal in patients 1, 2, and 4, and the intrahepatic ducts were normal at autopsy in patient 1. In patient 3, the common bile duct was dilated, while the intrahepatic ducts were dilated only slightly due to the stones in the bile duct. Because these cases were diagnosed in one hospital over a 10-yr period, this condition may be more common than is generally recognized.

4348 RECTAL BIOPSY IN TYPE 4 GLYCOGENOSIS: AN ULTRASTRUCTURAL CYTOCHEMICAL STUDY. (Eng.)

Cantin, M.; Brochu, P.; Turgeon-Knaack, C.; Berdnikoff, G.; Simard, P.; Morin, C. (Dept. Pathology, Universite de Montreal, 2900 blvd Edouard Montpetit, Montreal, Quebec H3T 1J4, Canada). *Arch. Pathol. Lab. Med.* 100(8):422-426; 1976.

Rectal biopsy material from an infant girl who died at 13.5 months from type 4 glycogenosis was studied by ultrastructural cytochemical methods. The patient's case report and autopsy findings are presented. The rectal mucosa, particularly the surface epithelium, was filled with large, vacuolated macrophages containing filamentous material and small granules. There were no α-rosettes of glycogen. The filamentous material was stained by the Thiery method (periodic acid-thiocarbohydrazide-silver proteinate) after 18 hr of exposure to thiocarbohydrazide. β-Glycogen particles were seen within 30 min. Autopsy showed notable icterus, 550 ml of ascitic fluid, an enlarged cirrhotic liver, and splenomegaly. Large macrophages filled with PAS-positive, diastase-resistant material were found in the mucosae of the rectum, colon, and appendix, in the spleen and lymph nodes, and in the hepatic, Kuppfer, myocardial, and tongue muscle cells. The results suggest that the Thiery technique, when combined with other methods, may be a useful tool for the diagnosis of type 4 glycogenosis.

4349 BEHAVIOUR OF e ANTIGEN AND ANTIBODY DURING CHRONIC ACTIVE LIVER DISEASE: RELATION TO HB ANTIGEN-ANTIBODY SYSTEM AND PROGNOSIS. (Eng.)

Vogten, A. J. M.; Summerskill, W. H. J.; Gitnick, G. L.; Schalm, S. W.; Smith, J. L.; Murphy, B. L.; Maynard, J. E. (Mayo Foundation and Medical Sch., Rochester, MN). *Lancet* 2(7977):126-128; 1976.

Serial determinations of e antigen and e antibody (anti-e) were made in 20 patients with chronic active liver disease (CALD) and hepatitis B surface antigen (HBsAg) or antibody (anti-HBs). Five patients had anti-HBs and 15 had HBsAg. Sera from 30 age- and sex-matched control patients with CALD, but without HBsAg or anti-HBs, who were followed-up for similar lengths of time, served as controls. Of the 20 HBsAg or anti-HBs-positive patients, 10 were e antigen-positive. Four remained so continuously, five lost the antigen during treatment, and, in one patient, the antigen appeared during treatment. All were HBsAg-positive and none lost HBsAg or developed anti-HBs. Only three achieved resolution or complete remission of their disease with prednisone therapy; five failed treatment, and two developed cirrhosis. Among the patients with HBsAg or anti-HBs but without e antigen, only three did not lose HBsAg and five others developed anti-HBs. Seven patients responded well to treatment. Two patients failed treatment, and two developed cirrhosis. Anti-e was temporarily present in three patients, two of whom also had anti-HBs. Only one patient with anti-e responded well to treatment. It is proposed that the presence of the e antigen is associated with impaired host-immune responses to hepatitis B virus infection and a poor prognosis.

4350 LIVER DYSFUNCTION AND HISTOLOGIC ABNORMALITIES IN NEONATAL HYPOPITUITARISM. (Eng.)

Herman, S. P.; Baggenstoss, A. H.; Cloutier, M. D. (Mayo Clinic, 200 First St. SW, Rochester, MN 55901). *J. Pediatr.* 87(6, part 1):892-895; 1975.

Two cases of neonatal aplasia or hypoplasia of the pituitary occurring with the neonatal hepatitis syndrome are reported. The first patient developed apnea, cyanosis, hypotonia, and generalized seizures at 24 hr of age. Serum bilirubin was 7.8 mg/dl, total. At 8 days of age, she was icteric; bilirubin was 8.6 mg/dl, total, and SGOT was 107 U/l. She had frequent hypoglycemic seizures, persistent jaundice, and a serum bilirubin level that peaked at 4.5 mg/dl. A wedge liver biopsy revealed numerous multinucleated giant hepatocytes, moderate bile stasis, a decreased number of interlobular bile ducts, and increased numbers of lymphocytes, histiocytes, fibroblasts, neutrophils, and collagenous connective tissue. At 12 months, the SGOT was 47 U/l and total serum bilirubin was 0.4 mg/dl. The insulin level was 1.7 μU/ml, while the glucose level was 9 mg/dl; at this time, the blood cortisol level was 2 μg/dl, and the growth hormone level was 1.5 ng/ml. Thyroid-stimulating hormone was 3.4 μU/ml. Hypopituitarism was diagnosed, and the patient improved with hydrocortisone and growth hormone therapy. The second patient was recognized as hypoglycemic at 12 hr of age. He was blind, icteric, the liver was palpable, SGOT was 89 U/l, and total serum bilirubin was 2.6 mg/dl. The wedge liver biopsy findings were similar to those of the first patient, although the giant cells were not as numerous or as large. The child remained free of seizures, and growth improved after 3 months of replacement thyroid and steroid therapy. The authors hypothesize that the absence of a hormone normally released from the pituitary might be responsible for the development of the liver dysfunction and histologic changes.

4351 ACID HYDROLASE ACTIVITIES AND LYSOSOMAL INTEGRITY IN LIVER BIOPSIES FROM PATIENTS WITH IRON OVERLOAD. (Eng.) Peters, T. J.; Seymour, C. A. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 50(1):75-78; 1976.

To clarify the mechanism of iron toxicity, iron, acid phosphatase, and *N*-acetyl-β-glucosaminidase were assayed in liver biopsy specimens from eight control subjects without liver damage, eight patients with idiopathic cirrhosis, six patients with untreated primary hemochromatosis, and eight patients with secondary hemochromatosis and thalassemia major. The activity of total acid phosphatase was significantly higher in the specimens of patients with iron overload (mean=27.5 mU/mg protein in primary hemochromatosis and 24.8 mU/mg in secondary hemochromatosis) than in those from either the controls (11.0 mU/mg) or the cirrhotic patients (12.1 mU/mg). The levels of latent *N*-acetyl-β-glucosaminidase were significantly decreased in the patients with primary hemochromatosis (29.0%) and secondary hemochromatosis (32.1%), in comparison with controls (66.5%) and cirrhotics (59.7%); the level of sedimentable *N*-acetyl-β-glucosaminidase was also decreased in patients with primary (32.5%) and secondary hemochromatosis (33.0%), in comparison with controls (67.8%) and cirrhotics (64.4%). These results indicated that lysosomes from the livers of patients with iron overload are more fragile than those of the other subjects. The authors suggest that iron accumulation damages the lysosomal membrane, releasing acid hydrolases into the cytoplasm and thus, initiating cell damage.

4352 DIFFERENTIAL DIAGNOSIS OF THE HEPATIC PORPHYRIAS. (Eng.) Anonymous. (No affiliation given). *Br. Med. J.* 4(5999):725-726; 1975.

A brief review of the literature concerning the differential diagnosis of hepatic porphyrias is presented. Porphyria presents either as an acute disease with abdominal pain, vomiting, and neuropsychiatric manifestations, or as a photosensitizing disease of the skin. The basis of diagnosis is the accurate measurement of porphyrin concentrations in urine, feces, and blood, usually by simple extraction techniques followed by spectrophotometric or spectrofluorometric measurement of the porphyrin fractions. Another promising method is high pressure liquid chromatography. Only three forms of hepatic porphyria are likely to present with skin lesions: cutaneous hepatic porphyria, variegate porphyria, and hereditary coproporphyria; of these, only variegate porphyria and cutaneous hepatic porphyria are likely to be confused. Normally they may be distinguished by the lack of familial history and the absence of porphyrin precursor excretion in cutaneous porphyria. The importance of the differential diagnosis of hepatic porphyrias is stressed as the current treatment of cutaneous hepatic porphyria, venesection, has little effect on variegate porphyria.

4353 AN AFLATOXIN IN THE LIVER OF A PATIENT WITH REYE-JOHNSON SYNDROME. (Eng.) Chaves-Carballo, E.; Ellefson, R. D.; Gomez, M. R. (Univ. Iowa Coll. Medicine, Iowa City, IA). *Mayo Clin. Proc.* 51(1):48-50; 1976.

Liver specimens from eight patients with Reye-Johnson syndrome, two patients with acute encephalopathy, and ten patients without liver disease were analyzed chromatographically for the presence of aflatoxins. The case report of the one patient in whom aflatoxin was found is presented. The patient was a 15-yr-old girl who died of Reye-Johnson syndrome (characterized by fever, cough, SGOT level of 133 U/l, blood ammonia level at 410 μg/dl, coma, apnea, cerebral edema with tonsillar herniation, and fatty liver). Maximum fluorescence emission in methanolic solution at 365-nm excitation was 425 nm for an unknown aflatoxin, 425 nm for standard aflatoxin B_1, and 450 nm for standard aflatoxin G_2. The infrared absorbance spectrum of the unknown aflatoxin corresponded closely with the infrared spectrum of aflatoxin B_1. The concentration was 22.5 μg/kg (measured as aflatoxin B_1). The differences in physicochemical properties between this substance and aflatoxin B_1 may have been caused by the fixation of the liver specimen in formaldehyde, which may have resulted in an aflatoxin derivative structurally related to aflatoxin B_1. It is suggested that aflatoxin analyses be performed whenever tissues are available from patients with Reye-Johnson syndrome.

4354 ACUTE LIVER FAILURE AND ENCEPHALOPATHY (REYE'S SYNDROME?) DURING SALICYLATE THERAPY.

(Eng.) Sillanpaa, M.; Makela, A.-L.; Koivikko, A. (Dept. Pediatrics, Univ. Turku, Turku, Finland). *Acta Paediatr. Scand.* 64(6):877-880; 1975.

A case of acute liver failure and encephalopathy occurring in a 13-yr-old girl during salicylate therapy (microcrystalline acetyl salicylic acid, 82 mg/kg/day) for joint pain and edema is reported. Salicylate was discontinued after 10 days, when the patient became confused and developed hematemesis, vertigo, convulsions, limb spasticity, elevated serum ammonium (130 μM), and elevated SGOT (≈3,000 U/l). The patient demonstrated the typical features of Reye's syndrome, but without acidosis and hypoglycemia. The patient became comatose, and an EEG exhibited strong general slowing and low amplitude activity intermingled with occasional spindle activity. The liver became enlarged. Two exchange transfusions, with a total of 5,000 ml of blood, were performed. After 60 hr, the patient regained consciousness and improved rapidly; the liver enlargement disappeared, and serum ammonium and SGOT decreased to normal levels. The patient was asymptomatic 10 months later, and the joint symptoms did not recur. In agreement with other reported cases of Reye's syndrome, this patient had serum salicylate concentrations that did not exceed the serum therapeutic levels.

4355 MORPHOLOGICAL CHANGES IN LIVER BIOPSIES FROM PATIENTS WITH RHEUMATOID ARTHRITIS.

(Eng.) Dietrichson, O.; From, A.; Christoffersen, P.; Juhl, E. (Kommunehospitalet, DK 1399 Copenhagen K, Denmark). *Scand. J. Rheumatol.* 5(2):65-69; 1976.

The hepatotoxic effect of long-term therapy with oxyphenisatin was investigated in 26 consecutive patients (aged 16-78 yr) with rheumatoid arthritis ranging in duration from 2 months to 34 yr. In all cases, liver biopsy, biochemical liver function tests, and determination of hepatitis B antigen were performed. Ten patients showed no pathological changes in the liver biopsy, and a further two patients had only non-specific changes. Seven patients had fatty liver, five had passive congestion, one had hemosiderosis, and only one had cirrhosis of the liver. The mean duration of treatment with oxyphenisatin, in the 12 patients without significant liver biopsy changes was 4 yr (0-19 yr range), and the duration for the 14 patients with an abnormal biopsy was 7 yr (0-33 yr range), which was not a statistically significant difference. No correlation was found between the activity of rheumatoid arthritis, the duration of the disease, the drug therapy given, and the liver damage. It is concluded that the majority of liver changes seen in rheumatoid arthritis are nonspecific and unrelated to the disease itself or to the drugs used in its treatment.

4356 PLATELET FUNCTION AND COAGULATION IN PATIENTS WITH WILSON DISEASE.

(Eng.) Owen, C. A., Jr.; Goldstein, N. P.; Bowie, E. J. W. (Mayo Clinic, Rochester, MN 55901). *Arch. Intern. Med.* 136(2):148-152; 1976.

Platelet function and coagulation were studied in 16 patients with Wilson disease (hepatolenticular degeneration). Five patients had a mild bleeding tendency that was characterized by easy bruising. Moderate thrombocytopenia (55-138 x 10^3 platelets/mm^3) was observed in three of the five bleeders and in two of the others. One bleeder was thrombocytotic (516 x 10^3 platelets/mm^3) and hyperfibrinogenemic (468 mg/dl). Bleeding times, platelet retention, and prothrombin consumption were rarely abnormal. However, 15 of the 16 patients had some abnormality of platelet aggregation: one, when ADP (1-20 μmol) was added to platelet rich plasma; three, when epinephrine (5.5 and 55 μmol) was added; and the remainder, when collagen was added. The collagen abnormalities were delayed or absent aggregation (5 patients, 4 of whom were bleeders) and absence of a change of shape (12 of the 16 patients). Platelet aggregation was completely normal in only one patient.

4357 GENETIC DEFECT OF CERULOPLASMIN SYNTHESIS IN LIVER POLYRIBOSOMES IN WILSON'S DISEASE.

(Rus.) Vakharlovskii, V. G.; Gaytskhoki, V. S.; Kiselev, O. I.; Moshkov, K. A.; Puchkova, L. V.; Shavlovskii, M. M.; Shulman, V. Sh.; Neyfakh, S. A. (Scientific Res. Inst. Experimental Medicine, Leningrad, USSR). *Dokl. Akad. Nauk SSSR* 222(3): 716-719; 1975.

The genetic defect of ceruloplasmin synthesis in liver polyribosomes was studied in biopsy specimens from patients with hepatolenticular degeneration and in patients with nonhepatic diseases (controls). The level of native ceruloplasmin chains in polyribosomes was studied by two specific immunochemical methods: immunoprecipitation of neosynthesized, polyribosome-bound polypeptide chains of ceruloplasmin and of complete ceruloplasmin polypeptides following short-term incubation of acellular liver preparations with ^{14}C-amino acids, and by quantitative assessment of the *in vivo* preformed ceruloplasmin-synthesizing polyribosomes by conjugation with ^{125}I-anti-ceruloplasmin immunoglobulins. Centrifugation in a saccharose gradient revealed the highest ^{125}I-antibody level in the relatively heavy polyribosome fraction (with 8-12 monoribosomes per messenger RNA molecule) in hepatolenticular degeneration, while the ^{125}I-antibody level was highest in the lighter polyribosomes (with 4-5 monomers) in the controls. A very substantial reduction occurred in the percentage of neosynthesized ceruloplasmin in the ^{14}C-labeled polypeptide fractions of polysomes, monoribosomes, and in free protein in the liver of patients with Wilson's disease. The findings indicate a significant reduction in the level of preformed native ceruloplasmin chains and of ceruloplasmin-synthesizing polyribosomes in the liver as the cause of the ceruloplasmin deficit in patients with hepatolenticular degeneration.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

4398 PHOTOTHERAPY. SHORT AND LONG-TERM COMPLICATIONS. (Eng.) Drew, J. H.; Marriage, K. J.; Bayle, V. V.; Bajraszewski, E.; McNamara, J. M. (Mercy Maternity Hosp., Clarendon St., East Melbourne, Victoria 3002, Australia). *Arch. Dis. Child.* 51(6):454-458; 1976.

The short and long term complications of the use of phototherapy for hyperbilirubinemia in 300 consecutively-treated infants were investigated. Phototherapy was begun when the serum bilirubin level was 12 mg/100 ml or greater in term infants and 10 mg/100 ml or greater in preterm infants. The age range at assessment of the treated infants was 8 to 24 months. The mean duration of phototherapy treatment was 35 hr (range 18-144 hr). Complications occurring during treatment included fever (150 infants), diarrhea (81), irritability (57), rash (35), and bronze baby syndrome (1 infant). Five infants died. No evidence of bilirubin encephalopathy or damage attributable to phototherapy was observed at autopsy. Eighty-nine infants were approximately 1 yr of age or more; 54 of these and 67 of 90 control infants were assessed in a longitudinal study. The overall incidence of major abnormalities detected included: abnormal Denver Developmental Screening Test (DDST) results in four treated infants; squint in five; and retrolental fibroplasia, ventricular septal defect, and atrial septal defect each in one infant. In the control group, there was one instance each of abnormal DDST, convulsions, squint, and funnel chest, and two cases of atrial septal defect. This study suggests that although phototherapy is a useful therapeutic agent, complications during its usage are common. It is suggested that phototherapy should not be used indiscriminately for hyperbilirubinemia until the results of further long term studies are available.

4399 BILIRUBIN IN BLOOD AND SPINAL FLUID IN JAUNDICED PATIENTS. (Por.) Lima, J. P.; Kalil, T. D.; Macedo, M. F. A. B. (Fundacao Faculdade Catolica de Medicina de Porto Alegre, Porto Alegre, Brasil). *Arq. Gastroenterol.* 12(2):95-103; 1975.

The presence of bilirubin in cerebrospinal fluid (CSF) and blood serum, and its relationship with xanthochromia, CSF proteins, and duration and intensity of the jaundice was studied in 30 icteric women with infectious hepatitis (20), intrahepatic cholestasis, and malignant or benign biliary tract obstruction (4 and 1, resp). The patients had no meningeal impairment or previous drug exposure capable of interfering with the bilirubin-albumin binding in the blood. In 14 control subjects with no liver diseases or neurological disturbances capable of altering the CSF, total serum bilirubin, CSF proteins, and the CSF leukocyte count were found within normal limits; only one had bilirubin (0.09 mg/100 ml, total) in the CSF. The patients with liver diseases presented asymmetrical levels not suitable for obtaining a linear correlation coefficient. They were consequently divided into group 1 (22/30 without bilirubin in the CSF) and group 2 (8/30 with 0.09-0.32 mg/100 ml total CSF bilirubin) and evaluated with the Student's "t" distribution test. No relation could be demonstrated between xanthochromia found in eight patients from group I and in six patients from group 2, and the CSF bilirubin levels. CSF protein levels showed no statistical difference between the two groups ($p<0.05$). A direct relationship was found between serum and CSF bilirubin and the intensity and duration of the jaundice; bilirubin in the CSF was mainly distributed among intensely icteric patients and patients with jaundice of longer duration. In both instances, the statistical difference between the two groups was $p<0.001$ and $p<0.025$, resp.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

4401 EPIDEMIC OF HEPATITIS IN MAN DUE TO AFLATOXICOSIS. (Eng.) Anonymous (No affiliation given.) *Nutr. Rev.* 34(2):45-46; 1976.

A report of an epidemic in India of hepatitis due to the consumption of maize heavily contaminated with *Aspergillus flavus* is reviewed. The epidemic was attributed to aflatoxicosis because: it occurred during the harvest of maize; it was confined to the poor who subsisted mainly on poorly stored maize that had been affected by excessive rain; it occurred in dogs that had shared the food; and it did not occur among inmates of a hostel, located in the same region, for whom maize was not the staple. The aflatoxin content found in random samples of maize varied from 6.25 to 15.6 ppm, which means that the affected subjects must have consumed 2-6 mg of toxin daily for almost 1 month. Aflatoxin B_1 was not found in any of several urine samples or in one liver sample. Two of seven serum specimens had traces of aflatoxin B_1, and histopathologic examination of the liver specimen showed multinucleated giant cells. This report incriminates aflatoxin in liver damage in man and shows that staples other than peanuts can become infected with *A. flavus*.

4402 HEPATITIS ASSOCIATED WITH DANTROLENE SODIUM. (Eng.) Ogburn, R. M.; Myers, R. L.; Burdick, G. E. (Letterman Army Medical Center, Presidio San Francisco, San Francisco, CA 94129). *Ann. Intern. Med.* 84(1):53-54; 1976.

A case of acute hepatitis in a 26-yr-old man being treated for Friedreich's ataxia with dantrolene sodium is presented. The patient initially received dantrolene (25 mg, 4 times daily) for 3 weeks; the treatment was discontinued at this time because it exacerbated his dysarthria. His SGOT was normal. Three and one-half years later, the treatment was reinstituted for 10 days, at which time increasing dysarthria forced a discontinuance of the treatment. The patient developed symptoms of hepatitis 14-21 days after discontinuing dantrolene treatment, but he did not manifest the fever, lymphadenopathy, rash, hepatomegaly, or systemic eosinophilia associated with diphenylhydantoin-induced hepatitis. His SGOT decreased from 740 mU/ml at admission to 52 mU/ml 22 days later; all other tests were normal. Twenty-four days later, a lower dosage of dantrolene (25 mg, twice daily) was given for 10 days, and again discontinued. On the 10th day, SGOT was 115 mU/ml, and total bilirubin was 2.1 mg/dl. The symptoms of hepatitis returned; SGOT was 1,150 mU/ml, bilirubin was 4.5 mg/dl, and there were prominent accumulations of eosinophils in the liver biopsy. The evidence suggests that dantrolene did cause hepatitis in this patient.

4403 DIPHENYLHYDANTOIN SENSITIVITY. A SYNDROME RESEMBLING INFECTIOUS MONONUCLEOSIS WITH A MORBILLIFORM RASH AND CHOLESTATIC HEPATITIS. (Eng.) Weedon, A. P. (Univ. Coll. Hosp., London, England). *Aust. N.Z. J. Med.* 5(6):561-563; 1975.

After 39 days of diphenylhydantoin (DPH) therapy, a 10-yr-old boy developed a syndrome resembling infectious mononucleosis combined with a morbilliform rash and cholestatic hepatitis. The rash was associated with fever and pharyngitis. The SGOT was 248 IU/l and increased to 400 IU then decreased. Serum bilirubin rose to 17.8 mg/100 ml, serum alkaline phosphatase was elevated at 625 IU/l, and the rash became exfoliative. A liver needle biopsy showed marked centrilobular cholestasis with some ballooning of hepatocytes. The portal tracts were edematous, and contained eosinophils and polymorphs. The patient gradually improved after 9 months of corticosteroid therapy (prednisone, 2.5 mg/kg/day), although his alkaline phosphatase level remained elevated at 850 IU/l. The patient's DPH dose was originally 300 mg/day; after 7 days it was reduced to 200 mg/day. After 18 days, his serum level was 23 μg/ml, and 8 days after discontinuing the drug, it was 3.1 μg/ml. These DPH levels exclude a metabolic defect with resultant toxic levels as an etiological factor in this syndrome. The fairly constant time lag from the onset of therapy to the development of symptoms, the eosinophilia, and the positive results of challenge doses in some previously reported cases with similar symptoms, all suggest that the syndrome is a rare reaction to DPH.

4404 DIAGNOSIS OF HALOTHANE-RELATED HEPATITIS. (Eng.) Moult, P. J. A.; Sherlock, S. (Royal Free Hosp., London NW3 2QG, U.K.). *Proc. R. Soc. Med.* 68(12):768-769; 1975.

Twenty-six patients who had become jaundiced within 2 weeks of receiving halothane anesthesia were studied to clarify the distinction between halothane and hepatitis B antigen-negative hepatitis. Only 1 of the 22 patients for whom temperature charts were available remained apyrexial. Coincidental virus A hepatitis was considered unlikely as the cause of jaundice in these patients for four reasons: there was a close temporal relation between exposure to halothane and onset of icterus; reactivation of latent infection was unlikely, as no relation was found between the severity of hepatitis and the degree of surgical stress; the mean age of these patients (56.4 ± 11.6 yr, 17 patients) was older than in a group of 19 virus A hepatitis patients (36.1 ± 16.4 yr); and of the 26 patients, 18 had received halothane twice within 28 days, while only 7% of unselected surgical patients received halothane. The authors suggest that unexplained jaundice after halothane administration is indicative of halothane sensitivity.

4405 LONG-TERM PERHEXILINE MALEATE AND LIVER FUNCTION. (Eng.) Howard, D. J.; Rees, J. R. (Bristol Royal Hosps., Bristol BS1 6SY, U.K.). *Br. Med. J.* 1(6002):133; 1976.

The long term effect of perhexiline maleate on liver function was studied in 6 men taking 200 mg per day and in 10 men taking 400 mg per day for an average of 12.5 months. Liver function was assessed during the treatment, 1 month after discontinuing the treatment, and during the following month, when the treatment had been reinstituted. Seven patients while on the drug had abnormal serum transaminase levels (>25 IU/l) at some time before the trial. In four patients, this abnormality resolved spontaneously, in two it resolved with reduction of the dose from 400 to 200 mg/day, and in one the levels were persistently abnormal at 25 IU/l. Aspartate aminotransferase was elevated in three patients, but did not exceed 32 IU/l; two patients developed the abnormality while off the drug. D-glutamyltransferase (DGT) was high in two patients on 200 mg and in six on 400 mg per day (mean= 49 ± 8 IU). Of the 12 patients able to complete the 1-month period without the drug, 7 had elevated DGT levels (31-100 IU) during the initial treatment; after the month without the drug, the levels in all patients decreased (17-58 IU) significantly. There was no statistically significant change after restarting the drug. Baseline BSP excretion was abnormal (>6 μM) in three men on 200 mg and in nine on 400 mg per day. Of the seven men who stayed off perhexiline maleate for a month, BSP retention decreased significantly from a mean of 10.4 μm to 5.1 μm at 45 min. Impotence was a side-effect of the drug in 12 patients, and dysuria was a side effect in 2 patients. The sensitive DGT and BSP excretion tests indicated liver-specific abnormalities in 50 to 75% of the patients. Since the results of these tests did not always run parallel, it is suggested that they measure independent features of liver metabolism affected to different degrees in different patients. The authors regard the abnormalities as acceptable in view of the success of perhexiline maleate in relieving anginal pain, but recommend treatment with the smallest effective dose.

4406 PELIOSIS HEPATIS IN A CHILD. (Eng.) Usatin, M. S.; Wigger, J. (Coll. Physicians and Surgeons, Columbia Univ., New York, NY). *Arch. Pathol. Lab. Med.* 100(8):419-421; 1976.

A case of peliosis hepatis in an 11-yr-old boy with cystic fibrosis is reported. His medications during the last 2 yr of life included methandrostenolone, acetylcysteine, phenylephrine hydrochloride, gentamicin sulfate, pancrelipase, vitamin B complex, vitamin K, pyridoxine hydrochloride, vitamin E, chlorothiazine, spironolactone, ampicillin trihydrate, gentamicin sulfate, and chloramphenicol. Death was due to a 50% pneumothorax on the right side, *Pseudomonas aeruginosa* sepsis, and worsening cardiopulmonary status. The liver changes corresponding to peliosis hepatis were blood-filled spaces of varying density, measuring from 0.1 to 0.8 cm. All spaces lined with endothelium were venous with mostly central veins. The lining sometimes showed transition to sinusoidal spaces, possibly from rupture. Other blood spaces were apparently surrounded solely by liver cell plates and appeared to be continuous with congested sinusoids. About 20-25% of the spaces were filled with thrombi in various stages of development. Platelet fibrin thrombi, hemosiderin deposition, cholestasis, vasculitis, and fibrinoid necrosis were absent. Chronic illness, long-term anabolic steroid therapy, and right ventricular congestive failure may all have contributed to the development of peliosis hepatis. Both the phlebectatic and parenchymal types, of which were previously thought to be separate, were found together in this case. This is compatible with its origin from right ventricular congestive failure. The rarity of peliosis, especially in children, indicates that other factors may be involved in its development.

4407 SALICYLATE HEPATOTOXICITY IN REITER'S SYNDROME. (Eng.) Ricks, W. B. (Dwight David Eisenhower Army Medical Center, Fort Gordon, GA 30905). *Ann. Intern. Med.* 84(1):52-53; 1976.

The case of an 18-yr-old man with Reiter's disease who developed salicylate-induced hepatotoxicity presented. The patient experienced pain in the right knee, a urethral discharge, and penile lesions. A biopsy of the penile lesion showed pustular psoriasiform lesions consistent with Reiter's disease. After 8 days of treatment with aspirin (600 mg, every 4 hr), the patient's SGOT had risen to 1,200 IU/l. SGPT was 1,000 IU, alkaline phosphatase was 160 IU/l, and total bilirubin was 1.0 mg/dl. The salicylate level was 24 mg/dl. Enzyme levels returned to normal after the aspirin was discontinued. A high frequency of HL-A W27 was observed in patients with Reiter's disease and in those with juvenile arthritis; this could be a marker or share a common location with a marker for hepatic sensitivity to salicylate

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

4410 REPETITIVE MATERNAL-FETAL TRANSMISSION OF FATAL HEPATITIS B. (Eng.) Fawaz, K. A.; Grady, G. F.; Kaplan, M. M.; Gellis, S. S. (Tufts-New England Medical Center, 171 Harrison Ave., Boston, MA 02111). *N. Engl. J. Med.* 293(26):1357-1359; 1975.

Two cases of fatal hepatitis in 3-month-old infants born successively to an asymptomatic carrier of hepatitis B surface antigen (HBsAg) are reported, and the literature is reviewed. The index patient, a boy, developed hepatitis after an uncomplicated gestation, full-term delivery, and 3 months of normal growth and development. HBsAg was detected by radioimmunoassay and counterelectrophoresis. Intramuscular injections of 3 ml of globulin with an anti-HBs titer of 1:500,000 in divided doses resulted in an increase in serum anti-HBs from zero to 1:256, peaking at 1:512, and a decrease in HBsAg to undetectable levels. The patient showed no clinical improvement and died on the 13th hospital day. Two years earlier, a 3-month-old female sibling developed similar symptoms, and she followed an identical clinical course. Massive hepatic necrosis was found at autopsy in both patients. Other authors have described hepatitis occurring in a total of 5% of infants born to 79 asymptomatic carriers of HBsAg. Retrospective studies imply that severe or fatal hepatitis B in the neonate is relatively more likely when the mother is an asymptomatic carrier of HBsAg, even though transmission of infection per se is most likely when she has acute hepatitis late in pregnancy or during the postpartum period.

4411 EVIDENCE FOR VIRAL HEPATITIS OTHER THAN TYPE A OR TYPE B AMONG PERSONS IN COSTA RICA. (Eng.) Villarejos, V. M.; Visona, K. A.; Eduarte, C. A.; Provost, P. J.; Hilleman, M. R. (Louisiana State Univ. International Center Medical Res. Training, Apdo 10155, San Jose, Costa Rica). *N. Engl. J. Med.* 293(26):1350-1352; 1975.

One hundred and three patients (64 with overt clinical hepatitis and 39 with subclinical infection as determined by liver function tests), who were residents of a community in Costa Rica in which hepatitis A and B are endemic, were examined for viral hepatitis other than type A or B. Antibodies against hepatitis A were detected by the immune-adherence assay, immunoassay and passive hemagglutination, resp., and for antibodies against cytomegalovirus by complement fixation. Twelve cases in which both type A and type B hepatitis were excluded on the basis of serologic testing were encountered; their case reports are presented. In all but one of these patients, cytomegalovirus infection was also excluded. The patients had not had blood transfusions, and available evidence pointed to person-to-person transmission. The illness in these patients was evidently neither hepatitis A nor hepatitis B and qualifies for consideration as the still hypothetical third type of hepatitis ("C"?).

4412 SANDED NUCLEI IN HEPATITIS B: EOSINOPHILIC INCLUSIONS IN LIVER CELL NUCLEI DUE TO EXCESS IN HEPATITIS B CORE ANTIGEN FORMATION. (Eng.) Bianchi, L.; Gudat, F. (Dept. Pathology, Univ. Basel, Basel, Switzerland). *Lab. Invest.* 35(1):1-5; 1976.

Nuclear eosinophilic inclusions due to excess hepatitis B core antigen (HBcAg) particles were identified and studied by electron microscopy and direct immunofluorescence in 96 liver biopsy specimens from patients with chronic hepatitis B virus infection. As the euchromatin space of affected nuclei was "sanded" by numerous core particles, with concomitant dissolution of the chromatin network, spiky, finely granular, and eosinophilic inclusions without a limiting membrane became visible in hematoxylin and eosin-stained paraffin sections. These HBcAg inclusions stained greyish pink with chromotrope aniline blue and were negative for orcein, the PAS reaction, and the Feulgen reaction for DNA. Sanded nuclei were detected exclusively in hepatitis B antigen (HBAg)-positive patients when a focal (in chronic aggressive hepatitis) or a generalized core forma-

LIBRARY U. OF

tion (in immunosuppressed kidney transplant recipients) was demonstrated by electron microscopy or immunofluorescence. In the former case, sections taken from 5 of 31 seropositive patients with chronic aggressive hepatitis had about 1% sanded nuclei in each section; in the latter case, the sections taken from 4 of 14 patients with immunosuppression had 1-3% sanded nuclei in each section. The presence of sanded nuclei in a persistent hepatitis B virus infection indicates an excessive core formation, the extent of which should be verified.

4413 HEPATITIS A: PERSPECTIVES AND RECENT ADVANCES.

(Eng.) Maynard, J. E. (Center for Disease control, 4402 North Seventh St., Phoenix, AZ 85014). *Am. J. Pathol.* 81(3):683-694; 1975.

Historical background, tissue culture studies, animal infectivity studies, preliminary characterization, classification, and strain characterization are emphasized in a review of hepatitis A. The basis for the epidemiologic and etiologic differentiation of hepatitis A and B was established in a series of studies undertaken between 1930 and 1970. Final recovery and visualization of the presumed etiologic agent of hepatitis A was not, however, accomplished until the technique of immune electron microscopy was applied to the examination of specimen materials collected from individuals in the early acute stages of infection. Morphologically homogeneous virus-like particles of 27 nm diameter have now been recovered from stools of patients with hepatitis A who were ill from a variety of sources. Antibody to these particles has been shown to develop during the course of infection with hepatitis A but not with hepatitis B, and disease has been induced in non-human primates inoculated with purified particle containing fractions. The classification of hepatitis A virus has not been conclusively established, but it would appear to be either a parvovirus or an enterovirus.

4414 THE RELATIONSHIP BETWEEN HEPATITIS B ANTIGEN, e-ANTIGEN, AND LIVER-PATHOLOGY IN PATIENTS TREATED WITH DIALYSIS.

(Eng.) Nordenfelt, E.; Lindholm, T.; Henrikson, H. (Univ. Hosp., Lund, Sweden). *Scand. J. Urol. Nephrol.* 9(3):277-281; 1975.

The relation between hepatitis B antigen (HBAg), e-antigen, and liver pathology was studied in 27 patients who had died after regular dialysis treatment. HBAg was determined by immunodiffusion and counterelectrophoresis, and e-antigen was determined by immunodiffusion. The examination of the liver histology was done without knowledge of the history of the patient. Seventeen patients were HBAg-positive at death and had been carriers of the antigen for between 1 and 57 months. Two had chronic aggressive hepatitis, and 10 had chronic persistent hepatitis, but 5 had no histological signs of chronic hepatitis. e-Antigen was found in blood samples from all of these patients. The cause of kidney diease, duration of dialysis, and time of carriership of HBAg showed the same variation among the patients without signs of chronic hepatitis as among those with positive signs. Two patients who had been HBAg-positive, but were negative at death, had no signs of chronic hepatitis. HBAg-positive samples available from one of these patients were also positive for e-antigen. Eight patients who were constantly negative for HBAg were also negative for e-antigen. One of them had autopsy findings of a chronic persistent hepatitis. There were thus very moderate or even no histological signs of chronic hepatitis among these patients, in spite of prolonged carriership of HBAg. A very close correlation between HBAg and e-antigen in dialysis patients was also discovered.

4415 PROPERTIES OF LYMPHOCYTES IN CHRONIC HBAg POSITIVE HEPATITIS. AN APPROACH TO PATHOGENETIC PROBLEMS.

(Eng.) Tolentino, P.; Pasino, M.; Braito, A.; Giacchino, R. (Dept. Infectious Diseases, Univ. Genova, via 5 Maggio 39, Genova, Italy). *Infection* 3(2):78-82; 1975.

Lymphocytes from 22 children with chronic hepatitis were studied and compared to lymphocytes from 32 healthy children, with respect to PHA dose-response curves, E-rosette formation, and membrane immunoglobulin (Ig). The PHA dose-response curves were displaced to the left (low PHA dose), DNA synthesis was significantly higher for all PHA doses tested (0.001-0.1 ml/ml of culture media), and the plasma of chronic hepatitis patients (CHP) acted neither as an inhibitor nor a stimulator. The percentage of E-rosette forming cells was constantly decreased in CHP. The mean value observed was 49.3%, with a range of 41.0-66.5%, compared to the mean of 69.8% with a range of 57.8-83.2% for controls. The total mean number of E-rosette forming cells/mm^3 for CHP (1,693/mm^3) was almost the same as that of the control group (1,675/mm^3). Distribution over a wide range was observed in CHP (886-2,668/mm^3) compared to controls (1,387-1,997/mm^3). The mean value of membrane immunofluorescent cells was 19.7% (788/mm^3) with a range of 6.0% (334/mm^3) to 35.4% (1,753/mm^3); this did not differ significantly from the control group. The results indicate that enhanced PHA-stimulation of lymphocytes occurs, at least in the chronic stage, as illustrated by PHA dose-response curves; this test is considered the most valid assessment of lymphocyte reactivity.

4416 CORRELATION BETWEEN FLUORESCENT ANTIBODY DETECTION OF HEPATITIS B CORE ANTIGEN IN LIVER BIOPSIES AND THE PRESENCE OF e ANTIGEN IN SERUM.

(Eng.) Murphy, B. L.; Peterson, J. M.; Smith, J. L.; Gitnick, G. L.; Auslander, M. O.; Berquist, K. R.; Maynard, J. E.; Purcell, R. H. (Bureau Epidemiology, Center Disease Control, Phoenix, AZ 85014). *Infect. Immun.* 13(1):296-297; 1976.

Liver biopsies and/or necropsy liver specimens (chimpanzee and human) taken from long-term carriers of hepatitis B surface antigen (HBsAg) were examined by fluorescent antibody techniques for HBsAg and hepatitis B core antigen (HBcAg). The biopsies were evaluated to determine whether HBsAg carriers of the e antigen demonstrate a more effective HBcAg synthesis than carriers without the e antigen. The presence of HBcAg in liver biopsy sections of both chimpanzees and humans was positively correlated with the detection of e antigen, and similarly, the absence of HBcAg was correlated with e antibody in the sera. HBcAg was detected in biopsies of 10 e antigen-positive subjects and in only 1 of 6 subjects positive for e antibody; this difference was statistically significant ($p<0.002$). These data suggest that the replication of hepatitis B virus may be more active in liver tissues of e antigen-positive HBsAg carriers than in those who are e antibody-positive.

4417 IMMUNE RESPONSE TO HBsAg AND THE SPECTRUM OF LIVER LESIONS IN HBsAG-POSITIVE PATIENTS WITH CHRONIC RENAL DISEASE. (Eng.) Galbraith, R. M.; El Sheikh, N.; Portmann, B.; Eddleston, A. L. W. F.; Williams, R.; Parsons, V.; Bewick, M.; Ogg, C. S. (King's Coll. Hosp. Medical Sch., Denmark Hill, London SE5, England). *Br. Med. J.* 1(6024):1495-1497; 1976.

Liver dysfunction was studied in 15 hepatitis B surface antigen (HBsAg)-positive patients with chronic renal disease. The immune responses to HBsAg and the associated histological changes in six patients receiving immunosuppressive therapy after successful renal transplantation were compared with those in the remaining nine patients, who were maintained on hemodialysis or by dietary protein restriction alone. Evidence of chronic hepatitis was found on histological examination in 9 out of 15 patients. Cirrhosis had already developed in three patients, who deteriorated rapidly and died. Liver biopsies from the remaining 12 patients showed evidence of chronic aggressive hepatitis in 2, chronic persistent hepatitis in 4, and minor histological lesions in 6. There were no significant differences in the incidence of the various histological lesions between patients maintained on hemodialysis and transplant recipients. The persistence of HBsAg in patients with renal failure or in those receiving immunosuppressive drugs after a transplant must indicate some impairment of the normal immune response to hepatitis B viral antigens. Nevertheless, cellular or humoral immunity to HBsAg was detected in all eight patients with chronic hepatitis tested compared with only one out of five with minimal liver lesions, suggesting that the severity of the liver damage may be directly related to the degree of immunocompetence.

4418 EFFICACY OF HEPATITIS B IMMUNE SERUM GLOBULIN AFTER ACCIDENTAL EXPOSURE. PRELIMINARY REPORT OF THE VETERANS ADMINISTRATION COOPERATIVE STUDY. (Eng.) Seeff, L. B.; Wright, E. C.; Finkelstein, J. D.; Greenlee, H. B.; Hamilton, J.; Leevy, C. M.; Tamburro, C. H.; Vlahcevic, Z.; Zimmon, D. S.; Zimmerman, H. J.; Felsher, B. F.; Garcia-Pont, P.; Dietz, A. A.; Koff, R. S.; Kiernan, T.; Schiff, E. R.; Zemel, R.; Nath, N. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Lancet* 2(7942):939-941; 1975.

The efficacy of hepatitis B immune globulin (HBIG) in the prophylaxis of viral hepatitis was compared with that of immune serum globulin (ISG) in individuals accidentally exposed to material infectious for hepatitis. The study was a randomized, double-blind, controlled trial. A preliminary evaluation of the first 302 of the 561 participants indicated that HBIG significantly reduced the frequency of clinical and subclinical hepatitis. When the analysis was restricted to only those 263 patients exposed to hepatitis B surface antigen (HBsAg)-positive material, the frequency of hepatitis in the group that received an i.m. injection of 5 ml of HBIG with an anti-HBs titer of 1/100,000 was significantly lower (1/134) than that in the group that received ISG having an anti-HBs titer of less than 1/8 (8/129). An anti-HBs titer of above 1/4 was detected in 60% of the recipients of HBIG and in 9% of the recipients of ISG, 2 weeks after the initial injection. Less than 10% of HBIG recipients had detectable anti-HBs by the sixth month after the injection, suggesting that HBIG should be given every 3-4 months to continually exposed individuals.

4419 THE EFFECTS OF ACUTE INFECTIOUS HEPATITIS AND CIRRHOSIS OF THE LIVER ON THE NONERYTHROPOIETIC COMPONENT OF EARLY BILIRUBIN. (Eng.) Tarao, K.; Fukushima, K.; Endo, O.; Kamiyo, A. (3-46 Urahunecho ninami-ku, Yokohama 232, Japan). *J. Lab. Clin. Med.* 87(2):240-250; 1976.

The nonerythropoietic component of early labeled bilirubin in plasma and bile was studied in 7 patients with acute infectious hepatitis during the late convalescent stage, in 13 patients with Laennec-type liver cirrhosis, and in 7 control subjects after i.v. injection of a tracer dose (2.5 μCi) of 4-^{14}C-δ-aminolevulinic acid. All subjects were examined during the nonicteric stage. In control subjects, the mean cumulative radioactivity readings in 4 hr were $29 \pm 4.7 \times 10^3$ d.p.m./mg x 4 hr in plasma and $27.0 \pm 1.2 \times 10^3$ d.p.m./mg x 4 hr in bile. In acute infectious hepatitic patients, the mean cumulative radioactivity readings for both plasma and bile in 4 hr were approximately twice that found in control subjects. In mild cirrhotic patients with enlarged liver on scintigram, the mean cumulative radioactivity readings for both plasma and bile were approximately 1.4 times that in control subjects. In patients with more advanced cirrhosis and markedly small livers on scintigram, the mean cumulative radioactivity readings for both plasma and bile were as low as approximately 0.5 that of control subjects. These findings indicate the important role of the liver in the production of the nonerythropoietic component of early bilirubin in man.

4420 GUILLAIN-BARRE SYNDROME IN ACUTE HBsAg-POSITIVE HEPATITIS. (Eng.) Niermeijer, P.; Gips, C. H. (Univ. Hosp., Groningen, Netherlands). *Br. Med. J.* 4(5999):732-733; 1975.

The case of a 21-yr-old woman who developed the Guillain-Barre syndrome in association with hepatitis B is reported. Neurological symptoms developed on day 20 after hospitalization for

LIBRARY U.

hepatitis. The patient was, at this time, negative for hepatitis B surface antigen (HBsAg). Spinal fluid protein was raised to 1.8 g/l, and the respiratory musculature was affected, making assisted ventilation necessary on day 24. From day 28, the patient improved neurologically, and at this time HBsAg conversion, accompanied by proteinuria, became apparent. At day 63, she had become positive for antibody to HBsAg (anti-HB), while bilirubin and transaminases had become normal. The transient proteinuria concurring with the conversion to HBsAg seronegativity may have been due to deposition of HBsAg/anti-HBs immune complexes in the glomeruli.

4421 STUDY DESIGN FOR A HEPATITIS B VACCINE TRIAL. (Eng.) Lustbader, E. D.; London, W. T.; Blumberg, B. S. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA 19111). *Proc. Natl. Acad. Sci. USA* 73(3):955-959; 1976.

A short-time trial using a small sample of patients for the evaluation of the hepatitis B vaccine was designed and applied to 223 patients who had had at least one blood specimen tested for both HBsAg and anti-HBs. The premise was that antibody to the surface antigen of the hepatitis B virus is protective against viral infection. It was verified by using the presence of the surface antigen as the marker of infection and by comparing infection rates in renal dialysis patients who had a naturally-acquired antibody to patients without antibody. Patients with antibody had an extremely low risk of infection. The probability of remaining uninfected decreased at an exponential rate for patients without antibody, implying a constant risk of infection at any point in time. The model estimated that at 9 months, there was a 50% chance of remaining uninfected, while at 24 months the probability dropped to 15%. Of the 64 patients who entered the trial with anti-HBs, 3 subsequently developed HBsAg. Twelve of the 159 patients entering without anti-HBs or HBsAg made anti-HBs before having HBsAg, and none of these subsequently developed HBsAg. The disadvantages and possible advantages of becoming infected with hepatitis B virus have not yet been fully evaluated. The results argue in favor of artificially stimulating the immune system to prevent infection with hepatitis B virus.

4422 STEROID THERAPY IN SEVERE VIRAL HEPATITIS: A DOUBLE-BLIND, RANDOMIZED TRIAL OF METHYL-PREDNISOLONE VERSUS PLACEBO. (Eng.) Gregory, P. B.; Knauer, C. M.; Kempson, R. L.; Miller, R. (Stanford Univ. Medical Center, Room S069, Stanford, CA 94305). *N. Engl. J. Med.* 294(13):681-687; 1976.

The effect of corticosteroid therapy in viral hepatitis was studied in 29 patients with severe viral hepatitis who were randomly assigned to methyl-prednisolone or placebo treatment groups. Forty-eight milligrams were given p.o. or parenterally in divided doses for the first 4 weeks of the study; the dose was then tapered to a range of 32-40 mg for 2 weeks, 16-32 mg for 4 weeks, and 12-32 mg for the last 6 weeks of treatment. The patients were evaluated on the basis of duration of jaundice, liver size, total bilirubin, alkaline phosphatase, SGOT, albumin, gamma globulin, prothrombin time (percent of normal activity and sec > control), smooth muscle antibody, and hepatitis B surface antigen. The two groups were comparable in clinical findings, laboratory results and the presence of bridging necrosis on liver biopsy. Seven of the 14 patients assigned to methyl-prednisolone and two of the 15 assigned to placebo died during the 16-week study period. Although the apparent excess mortality in the steroid-treated patients was not quite statistically significant (p=0.08), the trend persisted when only patients positive for hepatitis B surface antigen (p=0.08) or those with bridging necrosis (p=0.04) were analyzed separately. It is concluded that methyl-prednisolone does not enhance survival in patients with severe viral hepatitis, and it may be detrimental.

4423 PARTICULARITIES OF THE CLINICAL COURSE OF EARLY LIVER CIRRHOSIS DEVELOPMENT IMMEDIATELY AFTER SERUM HEPATITIS. (Rus.) Bunin, K. V.; Pak, S. G.; Brodov, L. E.; Tsoi, D. M. (First Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 47:12-15; 1975.

LIVER AND BILIARY TRACT

Chronic Hepatitis

4446 DETECTION OF A LIVER-MEMBRANE AUTOANTIBODY IN HB_sAg-NEGATIVE CHRONIC ACTIVE HEPATITIS. (Eng.) Hopf, U.; Meyer zum Buschenfelde, K. -H.; Arnold, W. (II. Medizinische Klinik der Universitat, 6500 Mainz, W. Germany). *N. Engl. J. Med.* 294(11):578-582; 1976.

Humoral immunity against hepatocellular membrane antigens was investigated in 52 patients with chronic active hepatitis, 46 patients with acute viral hepatitis, 14 patients with chronic persistent hepatitis, 8 healthy carriers of hepatitis B surface antigen (HBsAg), 6 patients with alcoholic liver cirrhosis, and 10 normal controls. Two different immunofluorescence patterns of immunoglobulin G (IgG) were observed on hepatocyte membranes. The membrane-fixed IgG on hepatocytes from patients with HBsAg-negative hepatitis showed a linear membrane fluorescence, but HBsAg-positive cases and some cases of protracted acute hepatitis B had a granular pattern. In patients with IgG bound to hepatocytes, continuing necrosis of parenchymal liver cells was seen. Conversely, hepatocytes without bound IgG were found in cases of chronic active hepatitis in remission, acute viral hepatitis without HBsAg and chronic persistent hepatitis, in healthy HBsAg carriers, and in patients with fatty liver or alcoholic cirrhosis. A liver-membrane autoantibody in serum, proved by fixation on membranes of isolated rabbit hepatocytes, was demonstrated only in HBsAg-negative chronic active hepatitis with elevated IgG concentrations. The results support the theory that different pathogenetic types of chronic active hepatitis exist, a so-called autoimmune type and a hepatitis virus-B-induced type.

4447 ANTIBODIES TO SMOOTH MUSCULATURE IN CHRONIC LIVER DISEASES. (Rus.) Bondar', Z. A.; Speranskii, A. I.; Podymova, S. D.; Nasonov, E. L. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 47:15-19; 1975.

Sera from patients with chronic liver diseases and from 20 healthy blood donors were investigated for the presence of antibodies to smooth musculature by indirect immunofluorescence, using serum antigammaglobulin conjugated with fluorescein isothiocyanate. The subjects included 26 patients with chronic active hepatitis, 10 patients with primary biliary cirrhosis, 16 patients with Laennec's cirrhosis, 21 patients with mixed cirrhosis, 4 patients with persistent hepatitis, 11 patients with systemic lupus erythematosus, 3 patients with systemic scleroderma, 9 patients with rheumatoid arthritis, and 7 patients with other unspecified diseases. Antibodies to smooth musculature were found in 54% of the patients with chronic active hepatitis, in 30% of the patients with primary biliary cirrhosis, in 6% of the patients with Laennec's cirrhosis, in 38% of the patients with mixed cirrhosis, and in 1% of the patients with unspecified diseases. No antibodies were found in serum samples from patients with persistant hepatitis, systemic lupus erythematosus, systemic scleroderma, rheumatoid arthritis, or in the healthy donors. The incidence of high antibody titers (>1:128) was highest in chronic active hepatitis and lowest in primary biliary cirrhosis. The findings indicate the value of the determination of serum antibodies to smooth musculature in the diagnosis of chronic active hepatitis.

4448 IMMUNOSUPPRESSIVE THERAPY AND VIRUS-CORES IN HBAg-POSITIVE CHRONIC HEPATITIS. (Eng.) Kendrey, G.; Szalka, A.; Laszlo, B.; Binder, L.; Hollos, I. (Zentral-Infektionsspital, d. Stadt, Budapest, Hungary). *Klin. Wochenschr.* 53(22):1081-1082; 1975.

Liver biopsies were carried out in a 38-yr-old woman before and during 6 months of immunosuppressive therapy (azathioprine, 50 mg/kg/day) for chronic active hepatitis and persistent hepatitis B (HB) antigenemia. Before the onset of therapy, virus cores were not detected by electron microscopy in the liver cell nuclei. Two biopsies taken during therapy showed intranuclear, ring-shaped virus-cores of 20 to 25 nm diameter in almost every hepatocyte. It has been previously suggested that similar cores might be the virus responsible for viral hepatitis.

4449 TWO IMMUNOLOGIC REACTIONS IN THE PATHOGENESIS OF HEPATITIS? (Eng.) Paronetto, F.; Popper, H. (Veterans Admin. Hosp., Bronx, New York, NY). *N. Engl. J. Med.* 294(11):606-607; 1976.

The possibility of two immunologic reactions being responsible for the chronicity of hepatitis is discussed. These two pathogenetic mechanisms are an immune reaction against viral products, and an autoimmune aggression that initiates or perpetuates liver-cell injury. The first mechanism is based on the discovery of Australia or hepatitis B-associated antigen (HBsAg) with the separation of the surface components (s) from the core (c). Various studies have suggested that elimination of antigen-carrying cells or suppression of the expression of the virus (which is based on the formation of both c and s) results in healing, whereas inadequate elimination explains chronicity. The second mechanism rests on the identification of a liver-specific antigen, which might be the target of an autoimmune attack. Other studies have shown that there are different types of gamma globulin deposition on the membranes of isolated hepatocytes, depending upon whether the patient is HBsAg-positive or -negative. These data support the theory of a dual origin of chronic hepatitis and incriminate different pathogenetic processes in HBsAg-positive and HBsAg-negative viral hepatitis. It is suggested that certain immune processes account for hepatocellular necrosis and chronicity of viral hepatitis, and that while some cases of HBsAg-negative hepatitis are primarily autoimmune disorders, in HBsAg-positive hepatitis cases, autoimmune aggression has only a supplemental role.

4450 PROGNOSIS OF CHRONIC HEPATITIS IN CHILDREN. (Cze.) Lukes, J.; Lukesova, M.; Zavazal, V. (Lekarska fakulta University Karlovy, 305 99 Plzen, Marxova 13, Czechoslovakia). *Cas. Lek. Cesk.* 114(36):1112-1115; 1975.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

4451 INABILITY OF CHRONIC ALCOHOLICS WITH LIVER DISEASE TO USE FOOD AS A SOURCE OF FOLATES, THIAMIN AND VITAMIN B$_6$. (Eng.) Baker, H.; Frank, O.; Zetterman, R. K.; Rajan, K. S.; ten Hove, W.; Leevy, C. M. (New Jersey Medical Sch., 88 Ross St., East Orange, NJ 07018). *Am. J. Clin. Nutr.* 28(12): 1377-1380; 1975.

The absorption of folates, thiamin, vitamin B$_6$, pantothenate, and riboflavin derived from yeast, and their respective synthetic forms was studied in 37 patients with liver disease due to alcoholism and in 12 healthy nonalcoholic subjects. The absorption of the vitamins was measured before, 2 hr after, and 5 hr after ingesting 35 g of brewer's yeast; 1 week later, the absorption test was repeated using the same concentrations of synthetic vitamins present as natural vitamins in yeast, i.e., 1.9 mg folylmonoglutamate, 21 mg thiamin HCl, 14 mg pyridoxine HCl (vitamin B$_6$), 7 mg riboflavin, and 210 mg calcium pantothenate. Patients with alcoholic liver disease had a mean peak increment (Δ, i.e., the difference in value between heights of plasma and whole blood vitamin activity before and after yeast or synthetic vitamins) for pantothenate (328 and 251 ng/ml after yeast and after synthetic vitamins, resp.) and for riboflavin (107 and 146 ng/ml, resp.) similar to that of healthy subjects (pantothenate: 258 and 219 ng/ml, resp.; riboflavin: 71 and 193 ng/ml, resp.). In contrast, the Δ for thiamin and vitamin B$_6$ was significantly depressed (4 and 37 ng/ml, resp.) after ingesting yeast in comparison to controls (10 and 71 ng/ml, resp.). Healthy controls had a mean Δ for folate of 34.6 ng/ml after ingesting yeast, while that for the alcoholics was only 5.1 ng/ml; however the Δ for folate increased to 49.0 ng/ml in the alcoholics after ingesting synthetic folylmonoglutamate (control value=32.8 ng/ml). One ml of plasma from alcoholics or controls increased the folate activity present in 1.0 mg of yeast from 0.5 ng (untreated with plasma) to 64 ng (treated with plasma as a source of folate conjugase); the plasma from healthy subjects and the alcoholics contained comparable folate conjugase activity. The folate, vitamin B$_6$, and thiamin deficits common in alcoholic liver disease probably result from the inability to absorb these specific vitamins from foods.

4452 SALIVARY STUDIES IN ALCOHOLIC CIRRHOSIS. (Eng.) Abelson, D. C.; Mandel, I. D.; Karmiol, M. (Sch. Dental Oral Surgery, Columbia Univ., 630 West 168th St., New York, NY 10032). *Oral Surg. Oral Med. Oral Pathol.* 41(2):188-192; 1976.

The composition of parotid saliva and the incidence of enlargement of this gland were determined in 18 patients with alcoholic cirrhosis and in 18 age- and sex-matched controls. Sodium, potassium, and calcium concentrations were determined in saliva samples by atomic absorption spectrophotometry. Parotid enlargements, usually bilateral, were observed in 11 of the 18 patients. Flow rate, potassium concentration, and calcium concentrations in the cirrhotic patients (1.3 ml/min, 24.6 mEq/l, and 2.9 mEq/l, resp.) were significantly elevated ($p<0.005$) over those of the controls (0.7 ml/min, 21.1 mEq/l, and 2.9 mEq/l, resp.). There were significant elevations of both total protein and amylase ($p<0.005$) in the cirrhotic group (355 mg% total protein in cirrhotic group versus 198 mg% in controls and 2,571 U/ml amylase in cirrhotics versus 1,267 U/ml in controls). Immunoglobulins G, M, and A, determined by immunodiffusion, were normal in both groups. Although the sodium concentration was also elevated in the cirrhotic patients, the output was actually lower than normal when the flow rate relation was considered. The increased flow rate and elevated protein and amylase levels indicate that hypertrophy and increased acinar function are components of the parotid enlargement commonly seen in alcoholic cirrhosis.

4453 PLATELET AGGREGATION IN PORTAL CIRRHOSIS. (Eng.) Ballard, H. S.; Marcus, A. J. (New York Veterans Admin. Hosp., 408 First Ave., New York, NY 10010). *Arch. Intern. Med.* 136(3):316-319; 1976.

Primary and secondary platelet aggregation in response to ADP$_1$ was studied in 24 alcoholic patients with portal (Laennec) cirrhosis and was compared with platelet aggregation in 14 normal subjects. In 12 patients with cirrhosis, platelet aggregation was diminished when compared to controls

Of the patients with impaired aggregation, 6 had elevated levels of fibrinogen-fibrin degradation products (FDP's, >8 μg/ml), 11 had thrombocytopenia (platelet counts ranged between 57,000 and 185,000 ml^3), 10 had shortened euglobulin lysis times (complete lysis within 90 min; controls, >1.5 hr), 4 had hypofibrinogenemia (79-198 mg fibrinogen/100 ml), and all had prolonged thrombin clotting times (>18 sec). The data suggest that elevated levels of serum FDP's do not explain fully the impairment of platelet aggregation or the prolongation of the thrombin clotting time that was noted in patients with advanced liver disease. A possible explanation for the prolongation of the thrombin clotting time is the presence of "altered" plasma fibrinogen.

4454 RELATION BETWEEN HEPATIC ALCOHOL DEHYDROGENASE ACTIVITY AND THE ASCORBIC ACID IN LEUCOCYTES OF PATIENTS WITH LIVER DISEASE. (Eng.) Dow, J.; Krasner, N.; Goldberg, A. (Stobhill General Hosp., Glasgow G21 3UW, Scotland). *Clin. Sci. Mol. Med.* 49(6):603-608; 1975.

Hepatic alcohol dehydrogenase activity and leukocyte ascorbic acid content were measured in 35 patients with liver disease and in 10 control subjects with duodenal ulcer. The patients with liver disease were divided into three groups consisting of 10 nondrinkers, 10 moderate drinkers (persons consuming over 4 pints of beer or equivalent more than 4 times per week), and 15 alcoholic/heavy drinkers. There was no significant difference in hepatic alcohol dehydrogenase activity between the groups with liver disease, but all patients had less than half the hepatic alcohol dehydrogenase activity of the control subjects (p<0.001). The ascorbic acid in leukocytes was significantly lower in the alcoholic/heavy drinker group (0.9 ± 0.5 fmol/cell) than that in the control subjects (1.4 ± 0.4, p<0.02) when the Student's *t*-test was applied, but no significant difference was found when the Mann-Whitney *U*-test was used. A correlation coefficient of r=0.77 (p<0.001) was observed among the 35 patients with liver disease when hepatic alcohol dehydrogenase activity was compared with leukocyte ascorbic acid content. An insignificant correlation (r=0.332) was found in the control subjects with no liver disease. This comparison was also significant among non-drinkers with liver disease (r=0.873, p<0.001), moderate drinkers (r=0.739, p<0.02) and alcoholic/heavy drinkers (r=0.702, p<0.005). The addition of ascorbic acid *in vitro* (0.5-10 mM) had no effect on the activity of alcohol dehydrogenase. The relation between hepatic alcohol dehydrogenase activity and leukocyte ascorbic acid content is probably a consequence of liver disease, as opposed to any specific effect of ascorbic acid deficiency or alcohol consumption on alcohol dehydrogenase activity.

LIVER AND BILIARY TRACT

Cirrhosis

4459 PRELIMINARY STUDY OF HEPATIC MICROSOMAL ENZYMES BEHAVIOR IN NORMAL AND CIRRHOTIC INDIVIDUALS. (Spa.) Escartin Marin, P.; Rossi, I.; Garcia Plaza, A.; Diaz Gil, J. J.; Gonsalves, M. (Centro Nacional de Investigaciones Medico-Quirurgicas de la Seguridad Social, Clinica Puerta de Hierro). *Rev. Clin. Esp.* 136(6):499-506; 1975.

The function of microsomal hepatic enzyme activity in cirrhotic subjects was investigated by determining the urinary D-glucaric acid excretion under normal conditions and after enzyme induction with phenobarbital. The b5 and P-450 microsomal cytochrome levels were also determined. Under normal conditions, the average D-glucaric acid excretion (evaluated as μM of glucaro-1, 4-lactone) in 20 patients with cirrhosis of the liver was slightly higher (7.1 μM) than in 20 control subjects (5.0 μM) without liver disease or previous exposure to drugs. This increase was attributed to the enzyme inducing action of alcohol, since all the patients had alcoholic cirrhosis and were drinking up to the time of hospitalization. The administration of phenobarbital (200 mg/d x 7) increased the average D-glucaric acid excretion by 8.8 μM in the controls, versus an increase of only 4.25 μM in the cirrhotic patients. Five patients showed no enzyme induction response. The concentrations of b5 and P-450 cytochromes (evaluated in M of microsomal pigments/mg of microsomal protein) were approximately 50% lower in six patients with advanced cirrhosis of the liver than in three patients with chronic hepatitis and in six healthy controls. The authors suggest that lower tolerance of drugs in patients with advanced parenchymal liver diseases may be partially caused by alterations of the microsomal enzymes.

4460 CYTOMORPHOLOGICAL STAINING OF NEEDLE BIOPSIES FROM CIRRHOTIC LIVER. (Cro.)

Rajcic, V. (Military Hosp., Zagreb, Yugoslavia). *Vojnosanit. Pregl.* 32(2):138-141; 1975.

Fifty stainings of needle biopsies from cirrhotic liver and 50 stainings of biopsies from normal liver were analyzed to determine whether there were morphological changes that were sufficiently characteristic to serve as the basis for establishing criteria for liver cirrhosis from cytological compounds. Moderate to pronounced morphological atypia of the hepatocyte nuclei were found in 45/50 cases of cirrhosis, while the findings were normal in 48/50 controls. All cytoplasms showed morphological atypia, while 44/50 controls had normal cytoplasm. Slight to pronounced vacuolization of the hepatocytes was observed in 30/50 cases of cirrhosis, but only slight vacuolization was found in 3/50 controls. Large to very large numbers of biliary epithelium cells were found in the smears of 47/50 cirrhotic cases, and only a small number of such cells was found in 11/50 control biopsies. Hypocellularity of the needle biopsy material, pleomorphism and vacuolization of the hepatocytes, and the presence of large numbers of biliary epithelium cells are the cytomorphological atypia which can be used for the diagnosis of liver cirrhosis.

4461 AN IMPROVED CHOLEDOCHOFIBERSCOPE AND NONSURGICAL REMOVAL OF RETAINED BILIARY CALCULI UNDER DIRECT VISUAL CONTROL.

(Eng.) Yamakawa, T.; Mieno, K.; Nogucki, T.; Shikata, J. (Sch. Medicine, Teikyo Univ., 2-11-1, Kaga, Itabashi-ku, Tokyo 173, Japan). *Gastrointest. Endosc.* 22(3): 160-164; 1976.

Experience with 126 operative and postoperative choledochoscopic examinations using an improved fiberoptic instrument is reported. The examinations were performed on 48 patients. The improved choledochofiberscope is 580 mm long and has a 250-mm flexible distal tip; there is no twisting torque between the proximal part and the distal end because the flexible part is shorter than a conventional choledochofiberscope. Retained stones in the bile ducts were found in 7 of the 29 cases surgically explored for calculous biliary tract disease. All stones were removed nonsurgically by visually guided and controlled instruments. In two of the seven cases, both operative and postoperative choledochoscopy were carried out; in the remaining cases only postoperative choledochoscopy was performed. Two of the seven cases, that of a 59-yr-old man who underwent surgery for cholecystolithiasis and choledocholithiasis and that of a 73-yr-old man who underwent cholecystectomy for cholecystitis and choledocholithiasis, are described in detail. Eight retained stones were revealed in the common hepatic and common bile ducts of the first patient by choledochoscopy and by a T-tube cholangiogram (performed 3 weeks after surgery). In the second patient, T-tube cholangiograms revealed small radiolucent defects throughout the biliary tract; choledochoscopy revealed two small cholesterol stones in the common bile duct. The stones were removed from both patients with a balloon-tipped catheter and basket forceps. The main value of choledochoscopy lies in the fact that retained or unsuspected stones, once their presence and positions are known, are usually readily removed with endoscopically-guided instruments

4462 THE FAILURE OF INTRA-ARTERIAL PITRESSIN INFUSION TO CONTROL UPPER GASTRO-INTESTINAL BLEEDING IN CIRRHOTIC PATIENTS.

(Eng.) MacKenzie, R. L.; Bury, K. D.; Provan, J. L.; St. Louis, E.; Marcon, N. (Wellesley Hosp. and Univ. Toronto, Toronto, Ontario, Canada). *J. Surg. Res.* 20(5): 505-508; 1976.

Experience with 24 cirrhotic patients in whom intra-arterial Pitressin (vasopressin) infusion was used in an attempt to control massive upper gastrointestinal bleeding is presented. Eight patients were bleeding from esophageal varices, 15 from gastric erosions, and 1 from both gastric erosions and esophageal varices. Pitressin (200 U) was added to 1 liter of either normal saline or 5% dextrose in water and was infused into the femoral artery at a maximum rate of 45 ml/hr (0.2 U/ml/min). Complete control of bleeding was obtained in only five patients. Twelve patients showed an initial response to Pitressin infusion but rebled at least once. No control of bleeding was achieved in seven patients. There were only four survivors in the entire group, two in the group where control was achieved and one each in the two latter groups. Complications of catheter placement arose in five patients, and these included ischemia of the ipsilateral leg, bleeding around the catheter, and ipsilateral thrombophlebitis. It appears that Pitressin infusion is of little value in the treatment of gastrointestinal bleeding in cirrhotic patients.

4463 THE EFFECT OF PROGESTERONE IN CIRRHOSIS.

(Eng.) Dinc, I.; Barlas, O.; Baban, N.; Baykut, F.; Oktay, E. (Cerrahpasa Faculty Medicine, Univ. Istanbul, Cerrahpasa, Istanbul, Turkey). *Med. Bull. Istanbul Univ.* 8(1):94-98; 1975.

Serum potassium, sodium, and sodium chloride concentrations, and the excretion of these substances and of aldosterone in 24-hr urine samples were determined in 10 cirrhotic patients (9 men and 1 woman) before and after treatment with progesterone (50-100 mg/day, i.m.). Treatment consisted of progesterone and dexamethasone, of progesterone and chlorothiazide, or of all three drugs. Gynecomastia disappeared after progesterone treatment in six patients, probably because of the anti-estrogenic action of progesterone. Following progesterone treatment, diuresis occurred in all patients, together with a significant increase in serum potassium and decreases in serum sodium and sodium chloride, indicating that progesterone has anti-aldosteronic properties.

4464 RESORPTIVE CAPACITY OF THE SMALL INTESTINE IN PORTAL HYPERTENSION. (Rus.) Lytkin, M. I.; Eremenko, V. P. (S. M. Kirov Military Medical Acad., Leningrad, USSR). *Klin. Med.* 53(10):90-95; 1975.

Small intestinal resorption of radioactivity labeled oleic acid, trioleate-glycerin, glucose, D-xylose, and albumin was studied 1-9 hr after administration in 104 patients with portal hypertension and liver cirrhosis (group 1), in 32 patients with extrahepatic portal hypertension without liver cirrhosis (group 2), and in 26 patients in whom decompression of the portal system was performed by splenorenal or mesentericocaval anastomosis for either form of portal hypertension (group 3). Considerable depression of resorption was found in either type of portal hypertension; the resorption of fatty acids and of the decomposition products of neutral fat was suppressed the most. Steatorrhea following the administration of neutral fat was more pronounced in group 1 than in group 2, indicating that the assimilation of neutral fat in liver cirrhosis is due to reduced resorption and to disorders of the hydrolytic processes, which result as a consequence of exocrine insufficiency of the pancreas. These changes were not correlated with the duration of the disease or with the value of the portal pressure. The glucose resorption was reduced in 79 of 100 patients in group 1 and in 22 of 30 patients in group 2. Similar findings were obtained for D-xylose. The reduction of the carbohydrate resorption was due to disturbances in active resorption and in the transport processes. The absence of changes in the protein resorption indicates that the dysproteinemia and hypoproteinemia of cirrhotic patients is basically due to disturbances in the protein synthesizing function of the liver and reticuloendothelial system rather than to disturbances in resorption from the small intestine. Normalization or improvement of the resorptive function of the small intestine was observed in group 3, 30-45 days after surgery.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

LIBRARY U. OF

4477 KINETIC ANALYSIS OF BILIARY LIPID EXCRETION IN MAN AND DOG. (Eng.) Wagner, C. I.; Trotman, B. W.; Soloway, R. D. (Univ. Pennsylvania Sch. Medicine, Philadelphia, PA 19104). *J. Clin. Invest.* 57(2):473-477; 1976.

The rates of biliary excretion of bile salts, cholesterol, and phospholipids were measured in man and dog to clarify the mechanisms involved in biliary lipid excretion, and to evaluate their role in cholesterol gallstone formation. Seven cholecystectomized patients with balloon-occludable reinfusion T-tubes were studied during intact and interrupted enterohepatic circulation and four cholecystectomized dogs were studied during interrupted enterohepatic circulation. In man and dog, both cholesterol and phospholipid outputs were hyperbolically related to bile salt output by the equation $y=x(a + bx)$. The output curves intersected the origin and showed an initial rapid rise, followed by a slower increase to a minimum, suggesting a rate-limited mechanism. The shape of the curves permitted calculation of the theoretical maximal outputs and the rates of rise to those outputs. Comparison of these values showed that in both man and dog, phospholipid output was greater than cholesterol output and that cholesterol and phospholipid were excreted at different rates. These studies indicate that cholesterol, phospholipids, and bile salts are not excreted in a fixed relation. In addition, the usefulness of the derived theoretical maximal lipid output and the rate of rise of lipid excretion to a maximum in evaluating the kinetics of biliary lipid excretion was demonstrated.

4478 GALLBLADDER DISEASE IN CHILDREN AND ADOLESCENTS. (Eng.) Andrassy, R. J.; Treadwell, T. A.; Ratner, I. A.; Buckley, C. J. (Wilford Hall USAF Medical Center, Lackland Air Force Base, TX 78236). *Am. J. Surg.* 132(1):19-21; 1976.

A review of 79 patients, 20 yr old or younger, who underwent cholecystectomy for gallbladder disease during a 5-yr period is presented. Particular emphasis was placed on duration of symptoms, etiology and associated illness. There were 69 female patients, 38 of whom were parous. Forty-one patients were overweight. Sixty-eight patients presented with epigastric or right upper quadrant pain; other frequent symptoms included intolerance to fatty food, nausea and vomiting, and bloating. All five black patients had hemoglobinopathies, although this was not seen in any of the other patients. Four of these patients had the sickle cell trait. Of the 10 patients who did not have stones, 2 had cholesterosis and 2 had subacute cholecystitis. Perforation of the common duct at the junction of the cystic duct, choledochal cyst, pancreatitis, and a positive culture for coagulase-negative staphylococcus were found in one patient each, and cultures revealed *Salmonella typhosa* in two additional patients. Oral cholecystograms were a safe and reliable method of diagnosis in 41 of 69 patients tested. Management consisted of cholecystectomy with drainage in all cases. This procedure was associated with no mortality and with 15 complications; these included 4 urinary infections, 2 upper gastrointestinal bleeding episodes, 2 wound infections, 1 case of phlebitis, 1 subhepatic abscess, 3 instances of atelectasis and fever, and 2 cases of unexplained fever. Cholecystitis should be considered early in the child or adolescent with unexplained abdominal pain.

4479 COMPARATIVE BILIARY CONCENTRATIONS OF CEPHAZOLIN AND CEPHALOTHIN IN PATIENTS WITH BILIARY TRACT DISEASE. (Eng.) Madhavan, T.; Block, M.; Quinn, E. L.; Cox, F.; Fisher, E. J.; Burch, K. H.; Haas, E. J. (Henry Ford Hosp., Detroit, MI). *Scott. Med. J.* 20(5):255-258; 1975.

The concentrations of cephazolin and cephalothin were measured in the bile and gallbladder tissue of 24 patients who were given one of the drugs prior to cholecystectomy. These levels were compared with those in the serum. Eight patients were given 1 g of cephazolin i.m., eight were given 1 g of cephazolin i.v., and eight received 1 g of cephalothin i.v. The antibiotics in the bile were determined by a modified cup-plate method using *Bacillus subtilis* as the test organism. The gallbladder contained less than 3 μg/ml cephazolin in four patients given the i.m. dose, and 7-42 μg/ml in the four other patients. The cephazolin concentration in the bile after i.v. administration was 18-195 μg/ml, or up to eight times the simultaneous serum level. The cephalothin level in the bile ranged from 4 to 20 μg/ml or 1.5-5 times the simultaneous serum concentration. The tissue levels of cephazolin following the i.v. dose ranged from 20 to 100 μg/g tissue, in comparison to only 1-4 μg/g tissue of cephalothin. The mean cephazolin concentration was 58.2 μg/g. The tissue cephazolin levels were similar to the peak serum levels, but cephalothin tissue levels were 3-20 times less than the peak serum concentration. The concentration of cephazolin in the common duct bile following the i.m. administration was higher than that in the serum, and ranged from 33 to 58 μg/ml 1 hr after dosing and 80-129 μg/ml at 2-2.5 hr. The total cephazolin concentration in the T-tube bile in one patient given 1 g, i.m., every 6 hr (9 doses) was 0.19% of the administered dose. The bile concentration rose after the serum level fell, indicating that the biliary excretion curve lagged behind the serum concentration curve. These studies indicate that the concentration of cephazolin in the serum, bile, and gallbladder tissue are considerably higher than that of cephalothin, especially with i.v. administration. These concentrations are in excess of the usual minimal inhibitory concentration for organisms associated with cholecystitis, and cephalozolin should thus be a useful antibiotic in gallbladder surgery.

4480 ENDOSCOPIC RETROGRADE BRUSH CYTOLOGY (ERBC) OF THE BILIARY AND PANCREATIC DUCTS.

(Eng.) Osnes, M.; Serck-Hanssen, A.; Myren, J. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 10(8):829-831; 1975.

The use of a new device for cannulation of the papilla of Vater is reported. It has a brushing tube that can be introduced through the biopsy channel of the duodenoscope (Olympus JF B). In 17 patients in whom endoscopic retrograde cholangiopancreatography (ERCP) had demonstrated ductal abnormalities, an endoscopic retrograde brush cytology (ERBC) was performed. A cytological diagnosis of malignancy was made in eight patients and a possible malignancy in two cases. Seven cases were operated upon, and a malignant tumor was found in six of these cases. In one case, a malignant tumor was found at autopsy. Histological examination was performed in six cases and showed adenocarcinoma in all. Two patients with malignant cells and ERCP-findings of suspected pancreatic carcinoma were not operated upon. The tumors were localized to the papilla of Vater in one case, to the biliary duct in two, to the pancreatic head in four, and to the pancreatic corpus in two cases. No complications occurred in any of the cases. It is concluded that this technique provides information supplementary to that of other diagnostic procedures.

4481 TRANSCYSTIC DUCT OPERATIVE CHOLANGIOGRAPHY: PERSONAL EXPERIENCE WITH 500 CONSECUTIVE CASES.

(Eng.) Farha, G. J.; Pearson, R. N. (Wichita State Univ. Branch, Univ. Kansas Sch. Medicine, Wichita, KS). *Am. J. Surg.* 131(2): 228-231; 1976.

A comparative study of the routine use of operative cholangiography was undertaken in 500 patients to determine the efficacy of the procedure in all cholecystectomies and to assess its accuracy when compared with clinical criteria. Of the cholecystectomy patients, 69 had clinical indications for common bile duct exploration, and 29 of these yielded stones for an overall accuracy rate of 42%. Of the 431 remaining patients, 36 demonstrated abnormal cholangiograms and in these, 26 yielded stones within the common duct, representing an incidence of 6% of unsuspected stones. Of the 500 patients, 61 showed cholangiographic indications for common duct exploration and 50 were positive for stones for an overall accuracy of 82%. The overall incidence of common duct stone recovery was 11%. Transcystic duct operative cholangiography should be performed routinely during cholecystectomy.

4482 OPERATIVE CHOLANGIOGRAPHY: CRITERIA WHICH MAKE EXPLORATION OF THE COMMON BILE DUCT DESIRABLE.

(Eng.) Marks, C. G.; Kelvin, F. M. (Radcliffe Infirmary, Oxford, England). *Br. J. Surg.* 63(1):51-54; 1976.

A previously reported set of criteria that make exploration of the common bile duct desirable was evaluated in 92 patients who underwent operative cholangiography. The overall accuracy of operative cholangiography in predicting stones in the common bile duct was 89%. The most reliable criteria in the diagnosis of the 40 patients who had calculi were: the presence of filling defect(s) in the common bile duct, which were present in 39 of 40 patients with calculi and in only 1 of the 52 normal patients; the absence of free flow of contrast medium into the duodenum, measured by the length of duodenum filled, which was present in 37 patients with calculi and in 5 normal patients, when a length of <2 cm was considered abnormal, and in 32 patients with calculi and 7 normal patients, when <7 cm was considered abnormal; and an abnormality of the terminal segment which was present in 35 patients with calculi and 6 normal patients. In 34 of the 40 positive explorations, the common bile duct diameter was 14 mm or less; 10 common bile ducts that contained stones were less than 10 mm in diameter. Excess filling of the intrahepatic ducts was often impossible to judge in the group with calculi, and was the least valuable criterion (present in 33 patients with calculi and 1 normal patient). The combination of filling defect(s) in the common bile duct and no free flow into the duodenum was the most accurate diagnostic combination, being positive in 92.5% of the 40 patients with calculi.

4483 A COMPARISON OF OPERATIVE CHOLANGIOGRAPHIC TECHNIQUES.

(Eng.) Evans, G. A.; Jenkins, D. H. R. (Robert Jones and Agnes Hunt Orthopaedic

Hosp., Oswestry, Wales, U.K.). *Br. J. Surg.* 63(6): 438-439; 1976.

The accuracy and postoperative morbidity of cystic duct cannulation by operative cholangiography in 51 patients were compared with the results of cholangiography performed by direct needle puncture of the bile duct in another group of 51 patients, all of whom underwent cholecystectomy. An additional 44 patients who underwent both cholecystectomy and choledochotomy, 19 following cystic duct cannulation and 25 following direct puncture, were also evaluated. There were no significant differences in the incidence of initial postoperative complications following the two methods of cholangiography, and the distribution of various types of complications was similar. The average postoperative hospitalization was 10.3 days in the needle puncture group, compared with 11.6 days in the cannulation group. Comparison of cholecystectomy alone and cholecystectomy with choledochotomy showed no significant difference in the incidence or distribution of complications. Six cholangiograms performed by cannulation had technical shortcomings, one case being abandoned owing to inability to cannulate the cystic duct. Other problems included poor quality radiographs (2), the presence of air bubbles (2), and the passage of the cannula into the duodenum (1). Two cases performed by common duct puncture had technical shortcomings due to poor quality radiographs. The authors suggest that when difficulties arise during cannulation of the cystic duct, direct needle puncture of the common bile duct will produce good quality radiographs and yield the same amount of diagnostic information, with no increase in operative morbidity.

LIBRARY U. OF

4484 OPERATIVE CHOLANGIOGRAPHY IN UNCOMPLICATED BILIARY TRACT SURGERY: REVIEW OF 354 CHOLANGIOGRAPHY STUDIES IN PATIENTS WITHOUT INDICATION OF COMMON DUCT PATHOLOGY. (Eng.) Wayne, R.; Cegielski, M.; Bleicher, J.; Saporta, J. (USPHS Hosp., Seattle, WA 98114). *Am. J. Surg.* 131(3):324-327; 1976.

The role of operative cholangiography in revealing unsuspected common duct pathology was assessed in 264 women and 90 men who had nonfunctioning gallbladders or cholelithiasis. A 20-gauge needle bent at an angle of 120 degrees and attached to a 10-cm^3 syringe was used to inject 30% Hypaque (10 ml, over a 1-min period) into the cystic duct, which had been tied at its junction with the gallbladder. Of the 354 cases, operative cholangiography showed normal results in 317. Twenty other patients had technically inadequate studies. All of the 17 patients with abnormal cholangiograms underwent common duct exploration. Three of these patients had a negative exploration (false-positive cholangiogram), 1 had cholangiocarcinoma, and 13 had stones. There was a total of 3.9% of patients with duct disease, unsuspected before cholangiography. The authors suggest that routine operative cholangiography combined with liver function tests may yield an even lower incidence of missed stones.

4485 SUGGESTED NEW RULES FOR EXPLORATION OF THE COMMON BILE DUCT AT CHOLECYSTECTOMY. (Eng.) Hugh, T. B. (St. Vincent's Medical Centre, 376 Victoria St., Darlinghurst, N.S.W. 2010, Australia). *Aust. N.Z. J. Surg.* 45(4):380-383; 1975.

A new set of guidelines for the exploration of the common duct, based on high-quality operative cholangiography (contact cholangiography), is outlined, and the place of supraduodenal and transduodenal routes for exploration is discussed. Results with 120 patients who underwent cholecystectomy are presented. If a stone is palpable in the common bile duct after mobilization of the duodenum, preexploratory cholangiography is omitted. If the stone is mobile, an attempt is made to manipulate it back into the cystic duct, so it can be removed with the gallbladder. If this maneuver is successful (as it was in two cases in this series), an operative cholangiogram is performed; if the cholangiogram is clear, the duct is not explored. If manipulation into the cystic duct is not successful, the stone is removed through a supraduodenal choledochostomy. If the stone is impacted in the terminal part of the duct, supraduodenal exploration is omitted, and transduodenal sphincteroplasty is performed. Sphincteroplasty is also done as the primary procedure when multiple, small stones can be felt or are seen on the x-ray film. In 102 cases, satisfactory cholangiograms were obtained, and no duct exploration was necessary. Stones were found in 14 of 18 cases that underwent exploration. Of 90 patients followed up for 1-4 yr, there has been no proven incidence of residual stone. The results suggest that if the cholangiogram is clear, it is safe not to explore the duct, and that this policy results in a satisfactorily low exploration rate (15%).

4486 FULMINANT CHOLANGITIS AND SEPTICEMIA AFTER ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY (ERC) IN TWO PATIENTS WITH OBSTRUCTIVE JAUNDICE. (Eng.) Thurnherr, N.; Bruhlmann, W. F.; Krejs, G. I.; Bianchi, L.; Faust, H.; Blum, A. L. (Kantonsspital Basel, CH-4004 Basel, Switzerland). *Am. J. Dig. Dis.* 21(6):477-481; 1976.

Two cases of obstructive jaundice with fatal septicemia occurring after endoscopic retrograde cholangiography (ERC) are reported. ERC was performed without difficulty, and both patients appeared to tolerate the procedure very well. ERC showed a clear-cut cause of obstruction in both patients. Multiple gallstones within the gallbladder, hepatic duct, cystic duct, and common duct were found in the first patient, a 54-yr-old woman; a dilated intrahepatic bile duct with a stenosis in the middle common duct due to a carcinoma was found in the other patient, a 51-yr-old man. A surgical procedure was planned for both patients, but delayed to a later and apparently more suitable date. Cholangitis and septicemia developed 72 and 24 hr after the procedure in the first and second patients, resp. The first patient died in septic shock 5 days later.

Blood cultures revealed *Pseudomonas aeruginosa*. The postmortem findings revealed multiple liver abscesses and purulent cholangitis. The second patient died of cardiac arrest following hemodialysis and regional heparinization for anuria 6 days later. The postmortem findings included a carcinoma of the common bile duct involving the cystic duct. There was a severe cholangitis with multiple liver abscesses, kidney abscesses, and an intraventricular cerebral hemorrhage. Blood cultures revealed *Enterobacter cloacae*. The authors suggest that, as in percutaneous transhepatic cholangiography, ERC should only be performed when surgery is planned within 24 hr; in addition, the patient should be treated with antibiotics as soon as the diagnosis of biliary obstruction is made.

4487 ACUTE TORSION OF THE GALLBLADDER: REVIEW OF THE LITERATURE AND REPORT OF A CASE.

(Eng.) Wetstein, L.; Attkiss, M.; Aufses, A. H., Jr. (108-23 Flatlands 9th St., Brooklyn, NY 11236). *Am. Surg.* 42(2):138-141; 1976.

The case of an 85-yr-old man with acute torsion of the gallbladder is presented. The patient presented with right epigastric pain, nausea, and recurrent vomiting. There was no cutaneous or scleral icterus, and the abdomen was scaffoid with no palpable organomegaly. At surgery, 100 cm^3 of seropurulent fluid was found in the peritoneal cavity, and the gallbladder was distended (measuring 15 x 6 cm in largest dimensions), smooth-walled, and purple-black. It had descended into the right lower quadrant and was hanging entirely free from the undersurface of the liver, to which it was attached by an elongated mesentery. The gallbladder was twisted 270 degrees around an axis represented by the cystic duct and cystic artery. It was totally infarcted without perforation, and multiple stones were found in the lumen. The patient recovered after detorsion of the gallbladder, cholecystectomy, and lavage of the peritoneal cavity. For the same reasons that the gallbladder is prone to torsion, it is also amenable to rapid and safe extirpation.

4488 ANOMALOUS LOCATION OF THE PAPILLA OF VATER.

(Eng.) Levine, M. P. (United States Air Force Hosp., Patrick Air Force Base, FL). *Am. Surg.* 42(2):135-137; 1976.

The case of a 69-yr-old woman in whom the common bile duct was found to enter the third (horizontal) portion of the duodenum is presented. The patient had a 10-yr history of episodic colicky upper right quadrant abdominal pain occasioned by fatty foods; she denied the occurrence of jaundice, flatulence, diarrhea, nausea, vomiting, weight loss, or melena. The patient underwent cholecystectomy, and an operative cholangiogram revealed the anomalous location of the papilla of Vater. This is the 38th reported case of this anomaly in the world literature. The anomaly may be responsible for failures during endoscopic retrograde pancreaticocholangiography.

4489 SURGERY OF BILIARY ATRESIA: CURRENT STATUS.

(Eng.) Lilly, J. R.; Altman, P.; Schroter, G.; Shikes, R. H.; Taubman, J. O. (Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80220). *Am. J. Dis. Child.* 129(12):1429-1432; 1975.

Experience with 34 infants with biliary atresia who were treated with hepatic portoenterostomy is reviewed. The success of the operation is contingent upon a proper recognition (confirmed by frozen section examination) and high transection of the extrahepatic biliary structure at the liver hilus and on a perfect placement of the enteric-biliary anastomotic sutures. Sustained bile drainage was obtained in 22 patients; the success rate undoubtedly would have been greater if all infants had been younger than 4 months at the time of diagnosis. However, 9 of 12 patients followed for up to 24 months showed progressive hepatic fibrosis in comparison to the appearance at the time of the portoenterostomy. In addition, all nine patients had a grossly abnormal intrahepatic biliary tree. Better control of cholangitis, a major postoperative complication in many of these infants, may improve these results. An intestinal Roux-en-Y anastomosis, in which a cutaneous double-barreled enterostomy is constructed, was used on the last 14 consecutive patients. The exteriorization of the intestinal segment draining the liver in these patients alleviated the frequency, duration, and severity of (but did not eliminate) ascending cholangitis. The evidence suggests that biliary atresia is an ongoing, obliterative disease involving the intra- and extrahepatic biliary trees. The portoenterostomy must be performed before the obliterative process of the extrahepatic tree is complete.

4490 PRIMARY CARCINOMA OF THE GALLBLADDER: STUDY OF 108 CASES.

(Eng.) Richard, P. F.; Cantin, J. (Hotel-Dieu Hosp., 3840 St. Urbain, Montreal, Quebec H2W IT8, Canada). *Can. J. Surg.* 19(1):27-32; 1976.

Experience with 108 cases of primary carcinoma of the gallbladder that occurred out of 17,698 cases of cancer, exclusive of skin cancer (incidence 0.6%), in one tumor registry is reported. Primary gallbladder carcinoma occurred mainly in women older than 60 yr. Abdominal pain occurred in most patients, and jaundice occurred in more than half. Weight loss was also common. Laboratory and radiographic features were nonspecific. The diagnosis was made or strongly suspected in only one-fourth of the patients. In many patients, the disease was not discovered until pathologic examination was conducted postoperatively. Resection was possible in 41 of the 93 patients who underwent operation, but treatment was conservative because it was palliative in 20. In 20 of the other 21 patients who underwent cholecystectomy, the disease was not recognized at operation. Overall, the 5-yr survival rate was 6.4%; for those who underwent curative resection, it was 33%, and for patients without visible metastases at operation, the mean survival

LIBRARY U. OF

was 3 yr. Cholecystectomy, wedge resection of liver, and resection of regional lymph nodes is the most effective treatment for this disease.

4491 EXCRETION OF METHYLPROSCILLARIDIN IN PATIENTS WITH A BILIARY FISTULA.

(Eng.) Staud, R.; Rietbrock, N.; Fassbender, H. P. (Klinikum Steglitz der FU Berlin, Hindenburgdamm 30, 1 Berlin 45, W. Germany). *Eur. J. Clin. Pharmacol.* 9(2/3):99-103; 1975.

Four patients with a biliary fistula received ^{3}H-methylproscillaridin (0.5 mg, p.o.) to determine whether the high fecal excretion of unchanged drug is due to inadequate intestinal absorption or to high biliary excretion. Fifty-five percent of the dose was excreted in bile, 16% in urine, and 3% in feces. Over 60% of the radioactivity excreted in bile and urine appeared within the first 24 hr. Seventy-eight percent of the radioactivity in bile consisted of $CHCl_3$-insoluble metabolites of methylproscillaridin; incubation of it with 5 mg of β-glucuronidase led to splitting off glucuronic acid from almost 80%. Methylproscillaridin can be regarded as the principal conjugated compound. Trichloroacetic acid-separation of $CHCl_3$-soluble compounds from bile showed identical running of radioactivity with methylproscillaridin, proscillaridin, and scillarenin and three unknown metabolites P_1, P_2, and P_3. In urine, the $CHCl_3$-soluble fraction averaged 16-34% of the total amount and was identified as methylproscillaridin, proscillaridin, scillarenin, P_2 and P_3. The relative composition of the total radioactivity in feces amounted to 77% methylproscillaridin, 4% scillarenin, and 12% polar metabolites. It is concluded that p.o.-administered methylproscillaridin is rapidly metabolized to $CHCl_3$-insoluble conjugates, which are mainly excreted in the bile. Accordingly, methylproscillaridin may be appropriate for the treatment of patients with impaired renal function.

4492 CHOLELITHIASIS IN A NEONATE.

(Eng.) Hughes, R. G.; Mayell, M. J. (Frenchay Hosp., Bristol BS16 1LE, U.K.). *Arch. Dis. Child.* 50(10):815-816; 1975.

The case of a neonate with cholelithiasis is reported. Laparotomy was performed on the 6-day-old boy because of unexplained vomiting. The only abnormality found was an inflamed gallbladder leaking yellow bile and containing three small stones. Cholecystostomy was performed, and the child was taking full feeds by the 12th postoperative day. Qualitative biochemical analysis of the stones showed them to be composed of cholesterol, calcium, and bilirubin. The child was not then and has not now been jaundiced. This is believed to be the youngest otherwise normal child with this disease.

4493 ARE ANTIBIOTICS NECESSARY IN ACUTE CHOLECYSTITIS?

(Eng.) Kune, G. A.; Burdon, J. G. W. (61 Erin St., Richmond, Victoria, Australia 3121). *Med. J. Aust.* 2(16):627-630; 1975.

The value of antibiotics in the treatment of acute cholecystitis was investigated in 302 cases. A total of 189 patients underwent surgery during an attack of acute cholecystitis. Broad spectrum antibiotics (such as tetracycline or ampicillin) were administered to 85 patients before surgery; no antibiotics were given to 104 patients. Local septic complications, such as empyema formation, perforation of the gallbladder with pericholecystic abscess, and gangrene of the gallbladder with local sepsis, occurred in 28 cases. Of the patients experiencing complications following surgery, 50% had received antibiotics. Broad spectrum antibiotics administered during and immediately after surgery were of value in lowering the risk of developing wound infection in patients with local septic complications of acute cholecystitis. Only three patients developed septicemia, none of whom were receiving antibiotics when the septicemia was discovered. No patient receiving broad spectrum drugs developed septicemia. Patients at risk were over 60 yr of age or had a debilitating disease, which lowers host resistance to infection, or already had a septic complication, such as pericholecystic abscess. Patients under 60 yr of age who have uncomplicated acute cholecystitis do not require antibiotics. It is concluded that antibiotics are valueless in decreasing the incidence of local septic complications, but are valuable in decreasing the number of wound infections and the incidence of septicemia in patients at risk.

4494 ANICTERIC CHOLECYSTITIS: WITH VERY HIGH SERUM GLUTAMIC OXALOACETIC TRANSAMINASE.

(Eng.) Adams, J. T.; Carter, S. L. (Univ. Rochester Medical Center, Rochester, NY). *N.Y. State J. Med.* 76(2):268-271; 1976.

The case report of a 26-yr-old woman with anicteric cholecystitis and an SGOT of 2,350 IU is presented together with a summary of three similarly anicteric patients with SGOT values of over 1,000 IU. Initially, a diagnosis of acute cholecystitis and coincidental serum hepatitis was made in the first patient, the latter part of the diagnosis being based on the very high SGOT value. She was treated with gastric suction, parenteral ampicillin, i.v. fluids, and meperidine hydrochloride. The patient improved rapidly; the SGOT value decreased rapidly, making a diagnosis of hepatitis unlikely. Laparotomy revealed gallstones and a common bile duct of normal size; a cholecystectomy was performed and the postoperative course was uneventful. The ages of the other three patients ranged between 19-54 yr. Two had had a normal gallbladder series within 6 months of the onset of their acute symptoms. All patients were treated with broad spectrum antibiotics, nasogastric suction, and i.v. fluids, and all showed improvement of symptoms within 72 hr after the onset of treatment; SGOT levels fell rapidly to achieve a normal value within 5 days from the time of onset of symptoms. Common duct exploration or operative cholangiogram was carried out in each patient, and in no instance was there recovery of, or demonstration of, common bile duct stones. It is concluded that although a very high SGOT is unusual in anicteric patients with acute cholecystitis, an awareness of ts possible occurrence is important to obviate rrors in diagnosis and treatment.

495 JAUNDICE IN PATIENTS WITH ACUTE CHOLECYSTITIS. ITS VALIDITY AS AN INDICATION OR COMMON BILE DUCT EXPLORATION. (Eng.) Cheung, . Y.; Maxwell, J. G. (Univ. Utah Coll. Medicine, 0 N. Medical Drive, Salt Lake City, UT 84132). *m. J. Surg.* 130(6):746-748; 1975.

o evaluate the validity of using jaundice as a riterion for choledochotomy, the incidence of aundice, the incidence of choledocholithiasis, he association of jaundice and ductal stones, and auses of jaundice other than choledocholithiasis ere investigated in 41 patients with proven holecystitis. Of the 33 patients in whom serum ilirubin was determined, 24 had elevated total ilirubin; this elevation was mild (1.2-3 mg/100 ml) n 16, moderate (3-6 mg/100 ml) in 6, and severe (>7 mg/100 ml) in 2. Of all 41 patients, only one ad ductal stones, and his preoperative serum biliubin level was 5.6 mg/100 ml. The remaining atients had no evidence of ductal stones, as deterined either by ductal exploration or by preoperaive and/or operative cholangiography. Jaundice oes not appear to be a compelling reason for choleochotomy, and less invasive techniques, such as i.v. and intraoperative cholangiography should sufice to exclude the possibility of common bile duct tone in patients with acute cholecystitis.

4496 EFFECT OF CHENODEOXYCHOLIC ACID AND PHENOBARBITAL ON THE RATE-LIMITING ENZYMES OF HEPATIC CHOLESTEROL AND BILE ACID SYNTHESIS IN PATIENTS WITH GALLSTONES. (Eng.) Coyne, M. J.; Bonorris, G. G.; Goldstein, L. I.; Schoenfield, L. J. (Cedars-Sinai Medical Center, Los Angeles, CA). *J. Lab. Clin. Med.* 87(2):281-291; 1976.

The effects of chenodeoxycholic acid (CDC, 750 mg/day), phenobarbital (PB, 90 or 180 mg), combined therapy (CDC + PB), and a placebo on biliary lipid composition and on the rate-limiting enzymes of hepatic cholesterol synthesis (HMG-CoA reductase) and bile acid synthesis (cholesterol-7α-hydroxylase) were studied. Percutaneous liver biopsies were performed after 6 months of therapy in four patients from each group participating in a double-blind study of gallstone dissolution. The enzyme activities were also assayed in liver obtained at laparotomy in seven untreated gallstone patients and in four without gallstones. 7α,12α-Dihydroxycholest-4-en-3-one-12α-hydroxylase was determined in four untreated gallstone patients and in four without gallstones. Untreated gallstone patients had 35% greater HMG-CoA reductase ($p<0.01$), 37% less 7α-hydroxylase ($p<0.01$), and 40% less 12α-hydroxylase ($p<0.01$) than patients without gallstones. CDC, PB, and both increased biliary CDC and decreased the lithogenic index significantly ($p<0.01$), but saturated bile persisted with PB. CDC decreased HMG-CoA reductase 40% ($p<0.01$) and 7α-hydroxylase 47% ($p<0.01$). PB increased HMG-CoA reductase 112% ($p<0.01$) and 7α-hydroxylase 20% ($p<0.01$). The combination of CDC and PB increased HMG-CoA reductase 40% ($p<0.01$) and had no effect on 7α-hydroxylase. In conclusion, CDC induced desaturation of bile while decreasing HMG-CoA reductase and increasing CDC in bile. PB reduced the saturation less effectively than CDC; it increased 7α-hydroxylase but also increased HMG-CoA reductase.

4497 GALLSTONE DISSOLUTION IN MAN USING CHOLIC ACID AND LECITHIN. (Eng.) Toouli, J.; Jablonski, P.; Watts, J. M. (Prince Henry's Hosp., Melbourne, Australia). *Lancet* 2(7945):1124-1126; 1975.

The effect of treatment with p.o. cholic acid (750 mg) and purified soybean lecithin (2,250 mg) daily for 6 months was studied in seven patients with radiolucent stones in the gallbladder and in two patients with radiolucent stones in the biliary tree. In two patients, the stones disappeared, and in one patient, the stones were reduced in size. Fasting bile samples were obtained, before and during treatment, in five patients and were assayed for cholesterol, bile acid, and phospholipid. In all five patients, the lithogenic index of bile was reduced during treatment. In each patient, the proportions of chenodeoxycholic acid and deoxycholic acid were reversed; the mean proportions were reversed from 40% and 10% of total bile acid initially to 12% and 48%, resp., after treatment. The proportions of cholic acid and lithocholic acid were unaffected. While it is known that p.o. administration of cholic acid alone does not dissolve gallstones, these studies suggest that a combination of cholic acid and soybean lecithin does lower the cholesterol saturation of bile and may promote gallstone dissolution. More extensive studies are necessary.

4498 THE TREATMENT OF PATIENTS WITH GALLSTONES BY LECITHIN. (Eng.) Tuzhilin, S. A.; Dreiling, D. A.; Narodetskaja, R. V.; Lukash, L. K. (First Moscow Medical Inst., Moscow, USSR). *Am. J. Gastroenterol.* 65(3):231-235; 1976.

The effect of peroral lecithin on gallstones and bile composition was investigated in eight patients. Lecithin (0.1 g, p.o., 3 times daily) was administered for 18 months to 2 yr. There was a decrease in the severity of the following clinical symptoms: frequency of acute abdominal attacks, dull abdominal pain, abdominal tenderness, and other abdominal signs (Ortner, Murphy, left diaphragm). There was a change in the composition of both B bile (gallbladder bile) and C bile (hepatic duct bile) before and after lecithin. The average mg% difference in B bile of the lecithin treated patients compared to 20 controls was $p>0.10$ for cholic acid, $p<0.001$ for phospholipids, $p<0.02$ for cholesterol, and $p<0.01$ for the cholate/cholesterol ratio. The average mg% difference in the C bile of the lecithin patients compared to 20 control subjects was $p>0.10$ for cholic acid, $p<0.01$ for phospholipids, $p>0.10$ for cholesterol, and $p<0.002$ for cholate/cholesterol ratio. In seven of eight patients,

LIBRARY U.

there was no change in the number or the size of the gallstones. In those instances in which cholecystography visualized a gallbladder, the radiologist reported a sharper outline of the viscus, and some decreases in size and clearer focus of stones. Although the results with lecithin treatment are not as dramatic as had been reported for chenodeoxycholic acid, these preliminary studies indicate alterations in bile composition, which are desirable in the dissolution of gallstones.

4499 COMPLICATIONS OF NONOPERATIVE EXTRACTION OF RETAINED COMMON DUCT STONES. (Eng.) Burhenne, H. J. (Children's Hosp. and Adult Medical Center, 3700 California St., San Francisco, CA 94118). *Am. J. Surg.* 131(3):260-262; 1976.

Complications in 612 patients who had undergone nonoperative extraction of retained common duct stones are reviewed. There was no mortality, but 33 patients showed some complications. Reoperation for failure of stone extraction was required in 9% of the patients. One of two patients who developed subhepatic bile collection required reoperation for drainage. One of three patients in whom papillomas of the common duct were mistaken for stones required another operation to remove the stone extraction basket caught on the papilloma. A third patient required a reoperation because a large stone was trapped in the stone extraction basket and could not be extracted through the sinus tract. All other complications subsided completely within 48 hr or less. Other complications included sinus tract perforations with extravasation of contrast (7 patients), fever (12 patients), *Escherichia coli* sepsis (2 patients), pancreatitis (2 patients), and vasovagal reaction (2 patients). Bile duct perforations or subdiaphragmatic abscesses were not reported in any of the cases. It is concluded that morbidity and mortality with this new procedure of percutaneous stone removal is significantly less than that with operative reexploration of the common duct. The authors recommend that a T-tube of no less than #14 French caliber should be used routinely during this procedure and that Penrose drains should be placed separately from the T-tube, and the T-tube should be brought out through a lateral stab wound.

4500 ACALCULOUS CLONORCHIASIS OBSTRUCTING THE COMMON BILE DUCT: A CASE REPORT AND REVIEW OF THE LITERATURE. (Eng.) Ameres, J. P.; Levine, M. P.; DeBlasi, H. P. (New York Medical Coll., New York, NY). *Am. Surg.* 42(3):170-172; 1976.

The case of a 37-yr-old man with acalculous clonorchiasis biliary tract obstruction is reported. The patient presented with epigastric and right upper quadrant pain, vomiting, and icterus. Cholecystectomy was performed because the gallbladder was distended. When the common bile duct was incised, fluid containing 10- to 20-mm leaf-like structures emerged. The parasites, later determined to be *Clonorchis sinensis*, were removed from the right, left, and common hepatic ducts. Cholangiography demonstrated dilated right and left hepatic ducts and irregular, blunted terminal biliary passages. Postoperatively, the patient drained several more parasites, but became anicteric and afebrile. This is the fourth reported case of acalculous clonorchiasis in which the major bile ducts were obstructed.

4501 PLASMA LIPIDS IN EXTRA HEPATIC BILIARY OBSTRUCTION. (Eng.) Mistilis, S. P.; Goren, R.; Tall, A. R.; Hickie, J. R. (Sydney Hosp., Sydney, N.S.W. 2000, Australia). *Aust. N.Z. J. Med.* 5(6):540-543; 1975.

Plasma lipids and lipoproteins were analyzed in 15 patients with proven extrahepatic biliary obstruction (EHO), in eight patients with Fredrickson Type IV hypertriglyceridemia, and in 23 controls to determine whether the lipid disturbances in EHO are confined to the phospholipids and cholesterol fractions and whether the hypertriglyceridemia found in isolated cases of EHO is a consistent symptom. Plasma lipids were compared before and after surgical relief of the obstruction in EHO. In the patients with EHO (aged 16-78 yr), compared with the controls (aged 18-63 yr), there was an increase in total cholesterol (EHO mean, 356.5 mg/dl; controls, 167 mg/dl) due to an increase in the unesterified fraction (EHO mean, 131.5 mg/dl; control, 119 mg/dl), to an increase in the unesterified to esterified cholesterol ratio (EHO mean, 2.3; controls, 0.38), to an increase in phospholipids (EHO mean, 465 mg/dl; controls, 186 mg/dl), and to an increase in the phospholipid to cholesterol ratio (EHO mean, 1.37; controls, 1.02). The most striking finding was a marked and persistent elevation of triglyceride (EHO mean, 289 mg/dl; control, 92 mg/dl). The increase in triglyceride was of a similar magnitude to cholesterol and phospholipid. Following relief of obstruction, the triglyceride returned to normal. The hypertriglyceridemia in cases of EHO was associated with a clear serum and negative cold aggregation test, in contrast to the changes in cases of endogenous type IV hypertriglyceridemia. Hypertriglyceridemia in EHO was associated with a broad beta fraction on the electrophoretogram. Lipoprotein-X was also detected and persisted after the relief of the obstruction, despite the return of other lipid changes to normal. Since lipoprotein-X is known to contain only 2-3% triglyceride, its presence does not account for elevated triglyceride levels. This suggests that triglyceride is being transported in either very low density lipoprotein particles or in a low density lipoprotein fraction other than lipoprotein-X, which is markedly increased in cholestasis

4502 THE EFFECTS OF HEPATIC PUNCTURES: AN ANALYSIS OF COMPLICATIONS FROM PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY IN 291 CASES, WITH SPECIAL EMPHASIS ON THE DEVELOPMENT OF INTRAHEPATIC TRAUMATIC FISTULAS. (Por.) Reibscheid, S.; Lederman, H.; Secaf, F.; Faria, P. A. J.; Ganc, A. J. (Servico de Radiodiagnostico do Hospital Israelita Albert Einstein). *Rev. Paul. Med.* 84(3/4):97-106; 1974.

Complications caused by percutaneous transhepatic cholangiographies (PTCh) are reported in 291 patients, of whom 51 had pancreatic tumors; 44 had tumors of the liver and bile ducts, 10 had metastatic hepatoma; 46 had choledocholithiasis; 23 had cicatricial stenosis from bilidigestive anastomosis; 31 had chronic pancreatitis; 18 had cholelithiasis, 64 had hepatitis, cirrhosis, postcholecystectomy syndrome, or schistosomiasis; and 4 had miscellaneous diseases. Complications occurred only when the PTCh could be completed (239/291 patients) and were easily corrected by subsequent surgery or medical treatment. Choleperitoneum was the most frequent complication and was observed in 11 patients, hematobilia occurred in 7 patients, fever in 4, puncture of the gallbladder in 3, hepatic laceration in 1, and air in the biliary passages in 1. One patient with choleperitoneum associated with hemoperitoneum died from generalized intravascular coagulation after corrective surgery (bilidigestive anastomosis). All cases of hemoperitoneum and hematobilia were asymptomatic, as were 3 of 11 cases of choleperitoneum. Previous or concurrent biliary infection in four patients was controlled by treatment with i.v. antibiotics. It is suggested that all complications, excepting one case of choleperitoneum with evident hepatic laceration, were induced by traumatic fistulae, which occurred without visible lesions and were caused by the trajectory of the puncture needle interfering with the elastic forces of the liver or with the coagulation mechanisms. PTCh is a useful method in differential diagnosis and postoperative or anatomopathological evaluation. The use of an image intensifier with television monitoring is compulsory; surgery, when indicated, must be performed soon after the PTCh, independent of the signs and symptoms of complications.

4503 EFFECT OF HEALTH RESORT TREATMENT ON THE DYNAMICS OF BIOCHEMICAL INDICES OF THE BILE IN PATIENTS WITH CHRONIC CALCULOUS CHOLECYSTITIS. (Rus.) Rospopa, V. A. (Ivano-Frankovsk Medical Inst., Ivano-Frankovsk, USSR). *Vrach. Delo* (1):53-55; 1976.

4504 FUNCTIONAL STATUS OF THE BILIARY SYSTEM IN YOUNG SCHOOL CHILDREN WITH AND WITHOUT CHRONIC CHOLECYSTOCHOLANGITIS. (Rus.) Sitnichenko, E. P. (Perm Medical Inst., Perm, USSR). *Lab. Delo* (9):546-548; 1975.

4534 HIGH INTESTINAL LACTASE CONCENTRATIONS IN ADULT ARABS IN SAUDI ARABIA.

(Eng.) Cook, G. C.; Al-Torki, M. T. (Univ. Riyadh, Riyadh, Saudi Arabia). *Br. Med. J.* 3(5976):135-136; 1975.

The maximum rise in blood glucose after the administration of lactose (50 g, p.o.) was found in 40 adult Arab patients without evidence of gastrointestinal disease, malnutrition, or diabetes mellitus. There were 14 Bedouin, 8 urban Saudi, 8 Yemeni, 1 Syrian, and 9 patients of mixed ancestory (usually partly African). Twenty-five of the Bedouin, Saudi, and Yemeni patients had an increase of over 1.1 mM (20 mg/100 ml) blood glucose, while two patients of mixed ancestory had the same increase. The Syrian patient had an increase of 0.6 mM. Most adult northern Europeans, Hamitic people of northern Africa, and Arabs in Saudi Arabia usually have high intestinal lactase concentrations. The persistence of high lactase levels probably originated in the Arabian peninsula. Its selective advantage may have been associated with the fluid and calorie content of camel's milk, which is important for survival in desert nomads.

4535 ESSENTIAL FATTY ACID DEFICIENCY IN HUMAN ADULTS DURING TOTAL PARENTERAL NUTRITION.

(Eng.) Riella, M. C.; Broviac, J. W.; Wells, M.; Scribner, B. H. (Dept. Medicine, Univ. Washington, Seattle, WA 98195). *Ann. Intern. Med.* 83(6):786-789; 1975.

The case reports of three patients who developed dry scaly skin lesions due to essential fatty acid deficiency while undergoing prolonged total parenteral nutrition are presented. The first patient, a 60-yr-old woman with advanced malnutrition secondary to short bowel syndrome, developed the lesions 46 days after the initiation of parenteral nutrition. The lesions were initially discrete and localized to body folds, but later became generalized. The second patient, a 53-yr-old woman with malabsorption secondary to intractable sprue, developed erythematous lesions after 6 months of parenteral nutrition. The third patient, a 13-yr-old girl with systemic mast cell disease and chronic malabsorption, developed lesions after 2 yr of parenteral nutrition. There was a marked elevation of 5,8,11-eicosatrienoic acid ($20{:}3\omega 9$; 7.4, 5.3, and 6.6% in the first, second, and third patients, resp.), and a high $20{:}3\omega 9$-to-$20{:}4\omega 6$ ratio (representing the severity of essential fatty acid deficiency) in all patients. When parenteral fat (Intralipid, 500 ml/day) was administered there was a progressive normalization of the abnormal lipid pattern and complete clearing of the skin within 14 days and 4 weeks in patients 1 and 2, resp.; in the third patient, only signs of urticaria pigmentosa were present after 6 weeks. Because more and more patients are becoming partly or totally dependent on parenteral nutrition for prolonged periods of time, the availability of parenteral fat preparations is urgently needed.

4536 PROTEIN ABSORPTION AND AMMONIA PRODUCTION: THE EFFECTS OF DIETARY PROTEIN AND REMOVAL OF THE COLON.

(Eng.) Gibson, J. A.; Sladen, G. E.; Dawson, A. M. (St. Bartholomew's Hosp., London ECIA 7BE, England). *Br. J. Nutr.* 35(1):61-65; 1976.

The effect of an increased dietary protein content on the amount of fecal nitrogen was measured in five subjects without functioning colons (3 with ileostomy and 2 with ileo-rectal anastomosis) and in six normal controls. All subjects were given a low (40 g/day)- and a high (100 g/day)-protein diet. In the controls, a 5-day equilibration period was allowed with each diet; in the test subjects, a 2-day period was allowed. By increasing the amount of dietary protein, an increase in blood urea concentration from 3.63 mM with the low-protein diet to 5.98 mM with the high-protein diet ($p<0.001$) was seen in all subjects. In controls, neither fecal nitrogen excretion nor fecal nitrogen concentration was increased significantly. The increase in the dietary protein content in test subjects resulted in a significant increase in both fecal nitrogen excretion and fecal nitrogen concentration ($p<0.05$ and $p<0.02$ for low- and high-protein diets, resp.). It is concluded that protein absorption by the small intestine is not 100% efficient and that an increase in dietary protein content results in a significant increase in nitrogen leaving the ileum. The findings confirm the rationale of the current practice of controlling NH_3 production in hepatic encephalopathy by dietary protein restriction.

4537 MUCOSAL ADHERENCE OF HUMAN ENTEROPATHOGENIC ESCHERICHIA COLI.

(Eng.) McNeish, A. S.; Fleming, J.; Turner, P.; Evans, N. (Inst. Child Health, Francis Rd., Birmingham B16 8ET, England). *Lancet* 2(7942):946-948; 1975.

The adhesion of enteropathogenic and nonenteropathogenic *Escherichia coli* strains to the mucosa of human fetal small intestine was measured by a newly modified *in vitro* assay. Intestinal fragments, approximately 15 mm^2, were taken from the jejunum of 28 fetuses and incubated with gentle rotation for 30 min or 1 sec in 1 ml of a suspension containing the test organism and 0.5% D-mannose. After washing and homogenization, the number of viable organisms released from each fragment was determined; the increase in the number of adhering organisms between 1 sec and 30 min of incubation was the measure of their mucosal adhesiveness. The mean increases in adhering organisms for the enteropathologic strains, 026 K60 H11 and 078 H12, were 4.15 and 3.82 $\log_{10}$ U, resp. These values were significantly greater ($p<0.01$) than for the non-pathogenic strains, 01 K1 H7 (mean 0.81 $\log_{10}$ U), 015 K14 H4 (mean 0.64 $\log_{10}$ U), and 075 K? H5 (mean 0). For the 026 K60 H11 and the 01 K1 H7 strains, the difference was significant at $p<10^{-7}$. Similar results were obtained whether the mucosa was used immediately or after 6-12 hr of organ culture. The adhesion to the mucosa of the pathogenic strains is not thought to be caused by common fimbriae; suspensions that were positive in the adhesion test did not cause hemagglutination, and there was no mucosal adhesion of the strain

(0.75 K? H5) that caused the strongest hemagglutination. Mucosal adhesion may be as important as enterotoxin production or invasiveness in determining the virulence of some strains of human enteropathogens.

4538 INTESTINAL ABSORPTION OF AMINO ACIDS AND PEPTIDES IN HARTNUP DISORDER. (Eng.)

Leonard, J. V.; Marrs, T. C.; Addison, J. M.; Burston, D.; Clegg, K. M.; Lloyd, J. K.; Matthews, D. M.; Seakins, J. W. (Inst. Child Health, London, England). *Pediatr. Res.* 10(4):246-249; 1976.

Absorption and renal clearances of amino acids were investigated in a 26-month-old girl (whose case report is presented) with Hartnup disorder. Plasma levels of amino acids were followed in the patient and in six normal adult controls before and 15, 30, and 45 min after the p.o. administration of an amino acid mixture simulating casein (5 and 10 g in patient and adults, resp.) and after the administration of an equivalent dose of a partial enzymic hydrolysate of casein containing oligopeptides in addition to free amino acids (4.7 and 9.4 g, resp.). In the adults, the increments in the plasma level of a given amino acid were similar whether the amino acid mixture or enzymic hydrolysate was given. In the patient, there was a large increase in plasma levels of lysine, arginine, and proline after both the amino acid mixture (resting levels 164, 78, and 137 μM for lysine, arginine, and proline, resp.; 149-189, 50-94, and 210-401 μM, resp., at intervals after amino acid mixture) and the enzyme hydrolysate (resting levels 152, 94, and 230 μM, resp.; 135-186, 44-57, and 89-274 μM, resp. after enzymic hydrolysate). There was neither an increase nor a decrease in plasma levels of glycine, histidine, tryptophan, serine, and glutamic acid after administration of the amino acid mixture, but there was an increase after the enzymic hydrolysate. The increments of alanine, valine, leucine, methionine, phenylalanine, and isoleucine after the enzymic hydrolysate were greater than after the amino acid mixture. After the amino acid mixture there was an initial rise of threonine in plasma levels, and after the enzymic hydrolysate, there was an initial fall. Renal clearances of proline, glutamic acid, asparagine, and lysine (0, 2, 2, and 2 ml/min 1.73 m^2, resp.) were normal, and those of arginine and glutamine were slightly increased (1 and 5 ml/min 1.73 m^2, resp.). The clearance of glycine was slightly increased (8 ml/min) and that of histidine, tyrosine, and serine plus asparagine, alanine, valine, leucine, isoleucine, methionine, phenylalanine, and threonine were greatly increased (86, 81, 24, 10, 41, 5, 6, 8, 13, and 14 ml/min, resp.). The authors conclude that the absorption of free glycine, histidine, tyrosine, and serine was probably severely impaired and that of valine, leucine, isoleucine, methionine, phenylalanine, glutamic acid, and alanine was subnormal. The results indicate that many neutral amino acids are malabsorbed in Hartnup disorder. Amino acids that are poorly absorbed in the free form are better absorbed from peptides. Most amino acids with a substantial increase in renal clearance are also poorly absorbed.

LIBRARY U.

4539 EFFECT OF LIVER FAILURE ON THE VENTILATORY RESPONSE TO HYPOXIA IN MAN AND THE GOAT.

(Eng.) Stanley, N. N.; Kelsen, S. G.; Cherniack, N. S. (Central Middlesex Hosp., Acton Lane, London NW10 7NS, England). *Clin. Sci. Mol. Med.* 50(1):25-35; 1976.

The ventilatory responses to transient and steady state hypoxia were measured in 10 patients with hepatic cirrhosis, in 10 healthy controls, and in 7 goats. The average ventilatory response to transient hypoxia in the patients was 0.91, significantly different from the 0.51 l/min % Sa, O_2^{-1} in the control subjects ($p<0.01$). The average response to steady state isocapnic hypoxia in the patients was 0.41 compared with 0.44 l/min % Sa, O_2^{-1} in the control subjects. The average difference between the responses to steady state hypoxia and transient hypoxia was 0.50 l/min % Sa, O_2^{-1} in the patients, which was significantly greater ($p<0.01$) than the average difference of 0.07 l/min % Sa, O_2^{-1} in the control subjects. All goats developed a respiratory alkalosis when in severe liver failure (experimentally induced). Compared to the initial baseline measurements, the Pa, CO_2 fell from an average of 5.43 to 4.16 kPa, and the average arterial pH increased from 7.404 to 7.446. There was no significant change in the average Pa, O_2. The ventilatory response to transient hypoxia rose from an average of 0.23 to 0.37 l/min % Sa, O_2^{-1} ($p<0.01$) after the development of liver failure, while the response to steady state hypoxia decreased slightly ($p<0.01$) to 0.20/min % Sa, O_2^{-1}. The ratio of the slope of the ventilation/Pa, CO_2 response line in hypoxia to the slope in hypoxia was 1.67 in the baseline studies, but it declined to 1.03 when liver failure was present. The Pa, O_2 values were similar during hypoxic hypercapnia and liver failure. The findings suggest that liver failure heightens the sensitivity of the peripheral chemoreceptors to the hypoxic stimulus, but may increase the tendency of the medullary centers to become depressed in hypoxia.

4540 VOLUME AND pH OF GASTRIC JUICE IN OBESE PATIENTS.

(Eng.) Vaughan, R. W.; Bauer, S.; Wise, L. (Univ. Arizona Coll. Medicine, Tucson, AZ 85724). *Anesthesiology* 43(6):686-689; 1975.

To determine whether obese patients are prone to the development of aspiration of stomach contents into the tracheobronchial tree, the pH, volume, and color of gastric juice were determined preoperatively in 56 obese patients and in 50 nonobese patients. All obese patients underwent jejuno-ileal small bowel bypass operations, while the nonobese patients underwent cholecystectomy, colonic resection, abdominal hysterectomy, or exploratory laparotomy. The combination of a low pH (<2.5) and a large volume of gastric juice (>25 ml) was found in 42 obese patients, while this combination was not found in the nonobese patients. There was no correlation between pH and the color of the initial aspirate. The pH medians for the obese and nonobese patients were 1.3 and 3.7, resp. The medians of the volume of gastric juice for the obese and nonobese patients were 37.7 and 11.0 ml, resp. These data suggest that particular care should be taken in the induction of anesthesia in obese patients.

4541 CELLULAR IMMUNE REACTIONS AGAINST COMMON ANTIGEN, SMALL INTESTINE, AND COLON ANTIGEN IN PATIENTS WITH CROHN'S DISEASE, ULCERATIVE COLITIS, AND CIRRHOSIS OF THE LIVER. (Eng.) Eckhardt, R.; Heinisch, M.; Meyer Zum Buschenfelde, K. H. (Second Univ. Medical Clinic, D-6500 Mainz, Langenbeckstrasse 1, W. Germany). *Scand. J. Gastroenterol.* 11(1):49-54; 1976.

Cellular and humoral immunity against common antigen (CA), microsomal antigens, and soluble antigens from human fetal small intestine and colon were measured in 41 patients with Crohn's disease and in 31 patients with ulcerative colitis. Cellular immunity against CA and intestinal antigens was also measured in 24 patients with liver cirrhosis. Seventy-one to 93% of the patients with ulcerative colitis and 64-91% of those with cirrhosis of the liver showed cellular immunity against CA and human fetal intestinal antigens, as measured by the leukocyte migration inhibition test (LMIT). Of the 24 patients with Crohn's disease who were not under immunosuppression, 38% showed cellular immunity against colon antigen; 50% of these 24 patients and 26% of 23 patients were below the normal range, using small intestine or CA as test antigens. Approximately 30% of patients with Crohn's disease and ulcerative colitis had elevated antibody titers against intestinal antigens and CA. Fifty-nine to 87% of the patients with ulcerative colitis showed a reciprocal relationship between cellular and humoral immunity, and 38-50% of those with Crohn's disease showed the same relation. Crohn's disease and ulcerative colitis can be separated in most cases by using intestinal antigens and CA in the LMIT. The occurrence of cellular immunity against these antigens cannot be interpreted as the only pathogenetic principle in these two diseases. There appears to be only a weak immune tolerance against intestinal antigens. The high percentage of cellular immune reactions in patients with cirrhosis of the liver demonstrates that they may have an impairment of the physiologic elimination of antigens by the liver.

Regional Enteritis

4576 EARLY COMPLICATIONS IN PATIENTS PREVIOUSLY TREATED WITH CORTICOSTEROIDS. A RETROSPECTIVE STUDY OF 250 OPERATIONS ON PATIENTS WITH CROHN'S DISEASE OR ULCERATIVE COLITIS. (Eng.) Knudsen, L.; Christiansen, L.; Jarnum, S. (Rigshospitalet, 2100 Copenhagen O, Denmark). *Scand. J. Gastroenterol.* 11(37):123-128; 1976.

A retrospective analysis of 205 major operations performed over a 10-yr period on 95 previously steroid-treated patients with Crohn's disease (CD) or ulcerative colitis (UC) is presented. All patients had been treated both in the medical and in the surgical gastroenterological departments. The patients were divided into three groups: group 1 patients received daily doses of >40 mg prednisone, which was withdrawn less than a week before surgery; group 2 contained those from whom the steroid was withdrawn from 1 week to 2 months before surgery; and group 3 patients did not receive steroids for the 2 months prior to surgery. For the CD patients, there was no demonstrable difference between the three groups in the incidence of operations without complications or the duration of the postoperative hospital stay. For the patients with UC, the incidence of complications, as well as the time in hospital, increased with increasing steroid treatment. Groups 1 and 2 did not differ significantly with regard to the duration of hospital convalescence ($p>0.05$), while this was the case for the groups 1-3 and 2-3 ($p<0.05$). The most frequent complications (wound infection, abscesses, fistulas, and pulmonary involvement) were related to the intensity of the steroid treatment for both disorders. Postoperative wound infections occurred more frequently in UC patients after high steroid doses than after low doses ($p<0.01$). The mortality rate, the duration of hospital convalescence, and the incidence of complications were significantly lower in patients who had undergone elective in preference to emergency surgery. It is concluded that the fear of an increased complication rate following intensive steroid treatment of patients with acute CD or UC is unfounded.

4577 NEUTROPHIL DYSFUNCTION IN CROHN'S DISEASE. (Eng.) Segal, A. W.; Loewi, G. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, U.K.). *Lancet* 2(7979):219-221; 1976.

The migration of neutrophils into skin windows was examined in 25 patients with Crohn's disease, in 31 patients with rheumatoid arthritis, and in 24 normal subjects. Neutrophils of the patients with Crohn's disease migrated out of skin windows over a 5-hr period in much smaller numbers (mean=0.25 ±

LIBRARY U. OF I.

0.15 x 10^6) than did those of the normal subjects (mean=1.3 ± 0.87 x 10^6) or those of patients with rheumatoid arthritis (mean=1.15 ± 1.13 x 10^6). This defect in Crohn's disease patients was unrelated to the site or extent of the inflammatory bowel lesions or to treatment. There was no statistically significant relation between the number of cells that migrated from skin windows in Crohn's patients and the ESR, serum albumin, hemoglobin, WBC count, or neutrophil count. Neutrophils from the Crohn's disease patients were normal on *in vitro* testing, indicating that the abnormal neutrophil function is secondary to a defective acute inflammatory response. Monocyte migration from skin windows after 24 hr was normal in the three patients with Crohn's disease that were investigated. A weak, acute inflammatory response to particulate or antigenic material in the bowel wall could result in the chronic inflammation observed in this condition.

4578 PERIPHERAL BLOOD AND INTESTINAL LYMPHOCYTE SUB-POPULATIONS IN CROHN'S DISEASE. (Eng.) Strickland, R. G.; Husby, G.; Black, W. C.; Williams, R. C., Jr. (Univ. New Mexico Sch. Medicine, Albuquerque, NM). *Gut* 16(11):847-853; 1975.

The nature and distribution of cells forming the inflammatory infiltrate in Crohn's disease were investigated in two patients by immunofluorescent techniques. Tissue from resected ileum (one patient) or colon (one patient) contained increased numbers of B and T lymphocytes compared with the corresponding control tissues. In tissue sections affected by Crohn's disease, immunohistological studies revealed a clear increase in lymphocytic infiltration in all layers of the bowel wall except within the superficial epithelium, and a difference in the distribution of T and B cells. In the mucosal lamina propria from either ileum or colon, a preponderance of B cells was observed. Sixty percent of the B cells were of the immunoglobulin (Ig) G class, 30% were of the IgA class, and 10% were of the IgM class. Only 25-30% of the lymphocytes in the lamina propria of the intestine involved by Crohn's disease were T cells. In the deeper layers of the bowel wall, T cells accounted for 60-70% of the lymphocytic infiltrate, while the proportion of B cells was 30-40%. Inflammatory cells bearing fragment crystallizable receptors were also present in the deeper layers of the bowel wall. Decreased peripheral blood T cell numbers returned to normal after resection of the involved bowel. These results are consistent with the view that many of the cellular immune abnormalities reported with varying frequency in Crohn's disease are secondary to immune intestinal sequestration and/or loss of lymphocytes.

4579 FOLIC ACID ABSORPTION IN REGIONAL ENTERITIS. (Eng.) Gerson, C. D.; Cohen, N. (Mt. Sinai Sch. Medicine, CCNY, New York, NY 10029). *Am. J. Clin. Nutr.* 29(2):182-186; 1976.

Intestinal absorption of folic acid by jejunal perfusion was investigated with a triple lumen tube in five patients with regional enteritis. The patients' intestinal disabilities ranged from terminal ileitis to short bowel syndrome. Two had steatorrhea and two had low serum folate levels. Labeled pteroylmonoglutamic acid (^{3}H-PGA) was added to the perfusion solution so that it contained total folic acid concentrations of 25 ng/ml with specific activity 0.04 μCi/ml. This resulted in perfusion of about 30 μg of PGA. Absorption of ^{3}H-PGA was in the normal range for all patients and slightly lower in two. Glucose absorption was also well maintained in all patients. The mean glucose concentration entering the study segment was 21 mM, and leaving the study segment, 7.1 mM, resulting in a logarithmic mean glucose concentration in the segment of 11.7 mM. Water and sodium absorption were in the normal range for four patients, although they were mildly depressed in a patient with the short bowel syndrome and recurrent disease. The results suggest that folic acid deficiency, common in regional enteritis, is largely caused by malnutrition, not malabsorption.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4585 ULTRASTRUCTURE OF THE SURFACE PRINCIPAL CELLS OF THE LARGE INTESTINE IN POSTNATAL DEVELOPING RATS. (Eng.) Ono, K. (Iwate Medical Univ., Morioka 020, Japan). *Anat. Embryol.* 149(2): 155-171; 1976.

The principal cells of the surface of the cecum, the ascending colon, and the descending colon in 90 neonatal rats (aged 25 days or less) were investigated using both light and electron microscopy. In 1- to 14-day old rats, the ultrastructure of the surface principal cells in the cecum and ascending colon were characterized by apical tubulo-vacuolar systems and large supranuclear vacuoles similar to those previously reported in the absorbing cells of the neonatal ileum. After about the 16th day, the special membrane system disappeared. In the descending colon, this special membrane system was absent from the cytoplasmic matrix of the epithelium. The author proposes that the proximal portion of the large intestine, together with the distal part of the small intestine, actively participate in the absorption of protein molecules during the early postnatal period.

4586 PLASMA LIPOPROTEINS IN RATS WITH EXPERIMENTAL BILIARY OBSTRUCTION. II. AN ULTRASTRUCTURAL STUDY. (Eng.) Pasquali-Ronchetti, I.; Calandra, S.; Baccarani-Contri, M.; Montaguti, M. (Istituto di Patologia Generale, Universita degli Studi di Modena, Modena, Italy). *Biochim. Biophys. Acta* 409(1):13-25; 1975.

The ultrastructure of plasma lipoproteins was studied in male Wistar rats with acute biliary obstruction in an attempt to define the relation between the lipid composition and the ultrastructure of these macromolecules. Biliary obstruction was produced in some rats by ligation and transection of the bile duct. Plasma lipoproteins were obtained by sequential preparative ultracentrifugation. The density (d)<1.006 g/ml fraction was found to contain two types of particles: vesicles having a mean diameter of 42.0 nm and spheroidal particles having a mean diameter of 80.0 nm. The latter showed surface irregularities that made these particles appear as spherical bodies with holes. The d=1.019-1.063 g/ml fraction was heterogeneous. Gel filtration on 2% agarose allowed the characterization of three components designated subfraction I, II, and III, resp. Subfraction I was composed of large aggregates of spherical and vesicular particles. Subfraction II consisted of 50.0- to 80.0-nm vesicles that were similar to artificially prepared emulsions of phospholipids in water. Subfraction III contained particles having a mean diameter of 20.0 nm and resembled low density lipoproteins of normal rats. The d=1.063-1.125 g/ml fraction contained 35.0-nm discoidal particles that tended to form rouleaux with a periodicity of 4.9 nm. This fraction also contained a few vesicles and 10.0-nm spherical particles similar to those found in the corresponding fraction of the normal rat. The abnormalities of plasma lipoproteins of biliary obstructed rats are similar to those observed in familial plasma lecithin: cholesterol acyltransferase deficiency.

4587 RICINOLEIC ACID (CASTOR OIL) ALTERS INTESTINAL SURFACE STRUCTURE. A SCANNING ELECTROMICROSCOPIC STUDY. (Eng.) Gaginella, T. S.; Phillips, S. F. (Mayo Graduate Sch. Medicine, Univ. Minnesota, Rochester, MN). *Mayo Clin. Proc.* 51(1): 6-12; 1976.

The effect of sodium ricinoleate, the active principle of castor oil, on the mucosal surface structure was investigated in the rabbit small intestine. The ileum of eight male albino rabbits was perfused with isotonic buffer or buffer containing 10 mM sodium ricinoleate. Mucosal biopsies were examined by scanning electron microscopy. The smooth, uninterrupted, and uniform surface of the control villus tip was interrupted by a cleft of the tip after fatty acid treatment. Clefts were seen in 60% of villi exposed to ricinoleate, while no changes were seen with control buffer. Clusters of cells were found lying within a typical cleft. These cells measured between 4 and 8 μm in diameter and appeared to be covered by stunted microvilli. The surface of the villus had the appearance of cracked clay. These changes were seen in more than 70% of individual villi (N>400) and in all biopsies (N=5) obtained from treated animals. The changes were not seen to the same degree or extent in controls and were due to tufting of microvilli. The capacity of ricinoleate and dietary long-chain fatty acids to evoke fluid secretion in the intestine may be related to these changes.

4588 THE EFFECTS OF ALTERATIONS IN VILLUS SHAPE ON THE INTESTINAL MUCOSAL SURFACE OF THE ALBINO RAT; THE RELATIONSHIP BETWEEN MUCOSAL SURFACE AREA AND THE CRYPTS. (Eng.) Kapadia, S.; Baker, S. J. (Christian Medical Coll. Hosp., Vellore 632004, Tamil Nadu, India). *Digestion* 14(3):256-268; 1976.

The influence of alterations in villus architecture on villus surface area was studied in inbred albino rats, and the relationship at different ages (2 weeks to 8 months) between villus surface area and the crypts was investigated. The number of villi increased up to the third month of age, and the number of crypts increased up to the eighth month. In the proximal intestine, the mean length of the villus base increased up to the fifth month as ridge-shaped villi were formed. Villus height was greater proximally than distally, and this, and the crypt depth, remained constant from the end of the first month. The total villus circumference per unit area of intestine, and the villus circumference per crypt, were the same proximally and distally and were relatively constant after the first month. The total circumference of the crypt mouths per mm^2 of intestine was the same proximally and distally and was greater than the total villus circumference at all ages. The villus surface area per mm^2 of intestine or per crypt remained relatively constant after the first month and was greater proximally than distally, due only to the taller villi proximally. The change from finger-shaped to ridge-shaped villi did not affect the villus mucosal surface area. The changes in villus shape are probably not determined by differences in the rate of crypt cell production.

4589 A DEMONSTRATION OF MICROVILLI ON THE LUMINAL SURFACES OF EPITHELIAL CELLS OF THE CANINE EXTRAHEPATIC BILIARY TRACT.

(Eng.) Tansy, M. F.; Salkin, L. M.; Kendall, F. M.; Innes, D. L.; Martin, J. S. (Temple Univ. Health Sciences Center, Philadelphia, PA). *Surg. Gynecol. Obstet.* 141(5): 699-704; 1975.

To determine differences in cellular morphology in the length of the canine extrahepatic biliary tract, scanning electron microscopy (SEM) was performed at progressively higher magnifications on the luminal surfaces of epithelial cells from the extrahepatic biliary tracts of six adult mongrel dogs. The entire extrahepatic biliary tract was divided into four specimens of approximately equal length, and each specimen was opened by a longitudinal incision. The plicated surface of the intramural mucosa was characterized by prominent folds. The morphologic structure of the surface changed abruptly at the boundary of the intramural and extramural portions of the common bile duct. There were abrupt morphologic changes between the extramural common bile duct and the cystic duct, where mucosal folds again dominated the luminal surface and the hepatic duct. The mucosal surface of the hepatic duct was characterized by parallel ridges, longitudinally aligned with the long axis of the duct. The mucosal folds were covered with epithelial cells, which were arranged in an orderly fashion, producing a cobblestone appearance. At higher magnifications, the mucosal surface presented a cratered appearance, and dome-shaped cells lined its walls and bottom. The cells were covered with microvillous projections. The epithelial folds of the cystic duct were also covered with dome-shaped cells, which were in turn covered with dense populations of microvillous projections. SEM of the epithelial surfaces of the hepatic ducts showed dome-shaped cells with superficial microvillous structures. The gross architecture of the epithelial lining appears to be correlated with discrete portions of the ductal system.

4590 ULTRASTRUCTURAL CHANGES OF THE CANINE GASTRIC MUCOSA AFTER TOPICAL APPLICATION OF GRADED CONCENTRATIONS OF ETHANOL.

(Eng.) Dinoso, V. P., Jr.; Ming, S. C.; McNiff, J. (Hahnemann Medical Coll. Hosp., 230 North Broad St., Philadelphia, PA 19102). *Am. J. Dig. Dis.* 21(8): 626-632; 1976.

Changes in the fine structure of the gastric mucosa following exposure to graded concentrations of non-acidified ethanol solutions were studied in mongrel dogs; the concentrations of protein, sodium, and potassium in the gastric contents were also measured. Three hundred milliliters of 12.5, 20, and 40%, vol/vol ethanol, were instilled intragastrically for 30 min. Mucosa from the midbody and midantrum along the greater curvature was examined by light and electron microscopy. Ethanol produced a gradation of changes in the surface epithelial cells and in the lamina propria without affecting the parietal cells and chief cells. Widened and irregular intercellular spaces were seen after treatment with 12.5% ethanol, while 20 and 40% ethanol disrupted the apical cell membrane with concomitant exudation of mucin into the gastric lumen. These changes were more severe after 40% ethanol. The tight junction between cells remained intact following exposure to the lower concentrations of ethanol, but focal separation of cell junctions occurred in severely damaged areas. Thirty min after exposure to 12.5, 20, or 40% ethanol, the concentrations of protein (14.95, 33.59, and 42.56 mg/ml, resp.), sodium (14.25, 29.25, and 36.00 mEq/l, resp.), and potassium (0.80, 1.82, and 1.83 mEq/l, resp.) were increased over those before treatment (protein: 2.78, 3.75, and 7.35 mg/ml for 12.5, 20, and 40% ethanol, resp.; sodium: 2.50, 1.25, and 1.75 mEq/l, resp.; potassium: 0.15, 0.16, and 0.19 mEq/l, resp.). These studies provide additional morphological data on the relationship between structural changes and functional abnormalities induced by agents which break the gastric mucosal barrier.

4591 ASPIRIN-INDUCED ULTRASTRUCTURAL CHANGES IN HUMAN GASTRIC MUCOSA: CORRELATION WITH POTENTIAL DIFFERENCE.

(Eng.) Baskin, W. N.; Ivey, K. J.; Krause, W. J.; Jeffrey, G. E.; Gemmell, R. T. (Harry S Truman Veterans Admin. Hosp., Univ. Missouri, Columbia, MO 65201). *Ann. Intern. Med.* 85(3):299-303; 1976.

The effect of aspirin on the gastric mucosal barrier was studied in seven normal subjects, and changes in potential difference and ultrastructure were correlated. The mean control potential difference was -48 ± 1.0 mV. Aspirin (600 mg, p.o., in 100 ml of saline) reduced the mean potential difference to -39 ± 1.4 mV ($p<0.001$) within 10 min. Gastric biopsies were taken during the control, aspirin-instillation, and recovery periods. Damage was present in all biopsies after aspirin; light microscopy showed focal cell disruption, loss of mucous granules, and apical membrane rupture. Transmission electron microscopy showed intact tight junctions. Scanning electron microscopy showed the loss of normal cobblestone cell apices, giving a honeycombed surface. Ten min after aspirin ingestion, 25% of the surface epithelial cells were damaged. Marked recovery was noted at 1 hr, with a normal potential difference and only 9% cell damage. It is concluded that single, routine doses of aspirin cause focal damage to normal human gastric mucosa.

ABSORPTION - EXCRETION - TRANSPORT

4598 ADAPTATION OF ELECTROLYTE AND WATER TRANSPORT IN THE CECUM. (Ger.) Loeschke, K. (II. Med. Univ.-Klinik, 8 Munich 2, Ziemssenstrasse 1, W. Germany). *Fortschr. Med.* 93(32):1613-1615; 1975.

To determine whether the intestine can adjust to specific changes in electrolyte transport, cecal wall changes were observed after addition of the polymer polyethylene glycol to the drinking water of rats. Cecal mass increased considerably, not through the enhancement of the size, but through increased numbers of mucosal cells. At the same time, Na-K-ATPase activity increased, suggesting that the rat cecal cells are able to adjust to changes in the electrolyte and water trnasport, not only with an increase in the number of cells, but also with a change in their functional properties.

4599 CALCIUM UPTAKE BY ISOLATED INTESTINAL BRUSH BORDER MEMBRANES FOLLOWING DIETARY CALCIUM RESTRICTION. (Eng.) Krawitt, E. L. (Dept. Medicine, Univ. Vermont, Burlington, VT 05401). *Life Sci.* 19(4):543-547; 1976.

Calcium uptake by isolated rat small intestinal brush border membranes was measured during the process of adaptation to dietary calcium deficiency. The administration of a calcium-deficient diet (0.01% calcium) for 10 days elevated the transport ratio in both everted duodenal and jejunal sacs ($p<.05$), in comparison to controls fed a diet containing 1.17% calcium. Activities of the marker enzyme, sucrase, indicated a comparable degree of purity of membranes from duodenum and jejunum isolated from both experimental and control animals; no statistically significant difference was observed comparing the values of activity from the duodenum (3.45 μmol sucrose split/min/mg protein) and jejunum (3.86 μmol) of controls to those of duodenum (3.18 μmol) and jejunum (4.9 μmol) of calcium-deficient animals ($p>0.05$). Uptake of ^{45}Ca by isolated membranes from the duodenum of calcium-deficient rats was elevated compared to the uptake by the membranes of controls, although no differences were seen in jejunal uptake rates. The results suggest that part of the adaptation producing increased intestinal transport by rats deprived of dietary calcium involves an increase in uptake by the duodenal brush border, independent of other components of the transport system.

4600 JEJUNAL XYLOSE AND GALACTOSE ABSORPTION IN THE RAT AS A FUNCTION OF INTESTINAL BACTERIAL FLORA AFTER THE ADMINISTRATION OF CYTOSTATICS. (Ger.) Bohmer, R.; Binder, R.; Rommel, K.; Dietrich, M.; Wolf, G. (Dept. Klin. Chemie, Zentrum fur Interdisziplinare Med., Univ. Ulm, D-7900 Ulm/Donau, W. Germany). *Z. Gastroenterol.* 14(1):30-40; 1976.

The correlation between xylose and galactose absorption in normal conventional rats, germ-free raised rats, and rats decontaminated with nonabsorbable antibiotics was investigated. Functional changes in the mucosa of the small intestine after administration of cytostatics were also examined. The monosaccharide absorption was determined by fractional small intestinal perfusion. No statistically significant differences in xylose absorption were seen between the three types of animals. Galactose absorption was decreased more significantly in germ-free rats than in the decontaminated rats. Three days after a single injection of cytostatics (daunorubicin hydrochloride, vincristine sulfate, or prednisone), xylose absorption was decreased in conventional and decontaminated animals compared to untreated rats. In the germ-free rats, xylose absorption was not affected by cytostatics, whereas galactose absorption was significantly elevated. In conventional and decontaminated animals, galactose absorption was unchanged after the administration of cytostatics.

4601 1-o-ACYL DERIVATIVES OF GLUCOSE AS NON-PENETRATING INHIBITORS OF GLUCOSE TRANSPORT BY HAMSTER SMALL INTESTINE IN VITRO. (Eng.) Ramaswamy, K.; Bhattacharyya, B. R.; Crane, R. K. (Univ. Texas Medical Sch. Houston, P.O. Box 20708, Houston, TX 77030). *Biochim. Biophys. Acta* 443(2):284-287; 1976.

The effect of 1-*O*-acyl derivatives of glucose on glucose transport was studied in everted sacs of hamster intestine. After 15 min incubation with 10 ml of a 1 mM solution of 1-*O*-propionyl glucose, 1-*O*-butyryl glucose, 1-*O*-henanoyl glucose, 1-*O*-octanoyl glucose, 1-*O*-decanoyl glucose, 1-*O*-dodecanoyl glucose, or 1-*O*-tetradecanoyl glucose, the concentration of acyl glucose in the tissue water was only 0.4, 1.9, 0.9, 0.5, 0.2, 0.2, and 0.9 mM, resp. The 1-*O*-acyl derivatives with 6, 8, 10, 12, and 14 carbon atoms inhibited the transport of 1 mM β-methyl glucoside by 24, 38, 81, 57, and 50%, resp. Using the representative compound, 1-*O*-decanoyl glucose, the inhibition was competitive with a K_m of 0.16 mM. The results show that the 1-*O*-acyl derivatives are nonpenetrating inhibitors. A carbonyl function in the substituent at C-1 renders the glucose derivative unable to be transported.

4602 ABSORPTION OF SHORT CHAIN FATTY ACIDS FROM THE HUMAN JEJUNUM. (Eng.) Schmitt, M. G., Jr.; Soergel, K. H.; Wood, C. M. (2300 North Rockton Ave., Rockford, IL 61101). *Gastroenterology* 70(2):211-215; 1976.

Jejunal absorption of the three predominant short chain fatty acids (SCFA), acetate, propionate, and butyrate, in small and large intestinal contents, was studied in five normal subjects to determine the association between excess SCFA production and diarrhea. A triple-lumen perfusion technique was employed; the test solutions were isotonic and contained 0, 5, 10, 25, 40, or 50 mM of an SCFA as the sodium salt. Intermittent secretion of small amounts of acetate (0.011-0.037 mmol/hr, cm) and butyrate (0.002-0.009 mmol/hr, cm) occurred during 3 of 15 control perfusion periods, and the concentrations measured in intestinal samples exceeded those reported for circulating plasma. The three SCFA's were absorbed rapidly and at equal rates. Absorption rates rose in apparently linear fashion, with the mean concentration in the study segment (up to 20 mM), but reached saturation at the higher concentrations present in the mixing segment. Water and sodium absorption increased slightly during butyrate absorption. The flow rate of fasting intestinal contents did not increase during SCFA perfusion. SCFA's are readily absorbed and do not exert a diarrheogenic effect in the normal human jejunum.

4603 EFFECT OF PREDNISOLONE AND SALICYLIC ACID ON IONIC FLUXES ACROSS THE HUMAN STOMACH. (Eng.) Ivey, K. J.; Parsons, C.; Weatherby R. (Royal Prince Alfred Hosp., Sydney, Australia). *Aust. NZ J. Med.* 5(5):408-412; 1975.

The effect of acute administration of prednisolone on ionic fluxes across the gastric mucosa was studied in five subjects; other experiments were carried out to determine whether prednisolone enhances the effect of salicylic acid on the mucosal barrier. Ionic fluxes were compared after instillation of test solutions of isotonic hydrochloric acid (160 mEq/l) alone or containing 20 mM salicylic acid or 10 mg of prednisolone, or both. Prednisolone produced no alteration in fluxes of H^+ and Na^+ ions compared with controls. Salicylic acid induced a significant net loss of H^+ ions (mean, -0.78 mEq/15 min) and gain of Na^+ ions (+2.10 mEq/15 min), indicating alteration of the gastric mucosal barrier. Combined salicylic acid plus prednisolone produced no increase in permeability of gastric mucosa to H^+ and Na^+ ions or to salicylic acid itself. Prednisolone was not appreciably absorbed from the stomach (<2% of the amount instilled), while salicylic acid was well absorbed (16%). The combination of salicylic acid and prednisolone did not increase absorption of either drug. Neither salicylic acid nor prednisolone solutions alone or combined caused an increase in pepsin output over that due to 160 mM HCl. Salicylic acid resulted in a significant fall in potential difference compared to control (from -55 to -51 mV with salicylic acid alone; from -54.5 to -49.5 mV with salicylic acid + prednisolone), while prednisolone produced no change in the one subject studied. In acute studies in man, prednisolone is not absorbed from the stomach, does not itself affect the gastric mucosal barrier nor pepsin output, nor does it enhance the absorption of or effect of salicylic acid on gastric ionic fluxes or pepsin output.

MOTILITY

4612 GASTRIC EMPTYING: TECHNIQUE OF MEASUREMENT AND SURGICAL IMPLICATIONS. (Eng.) van Dam, A. P. M.; Lubbers, E. J. C. (St. Radboud Univ. Hosp., Nijmegen, Netherlands). *Chir. Gastroenterol.* 9(4):453-456; 1975.

To determine the normal mean time of gastric emptying, 30 healthy subjects were given a test meal labeled with the technetium-antimony sulfur colloid, and the stomach was visualized by a gamma camera. In addition, the case reports of two patients in whom the gastric tracer study was valuable in the diagnosis of pyloric hypertrophy are presented. In the 30 subjects, the mean time in which half of the activity in the test meal left the stomach ($T_{1/2}$) was 47 min. In the two patients in whom radiological examination and gastroscopy failed to give evidence of pyloric hypertrophy, the $T_{1/2}$ values were greatly prolonged (122-240 min in one patient). Laparotomy and a successful pyloroplasty were subsequently performed. In both patients, the $T_{1/2}$ values were normal 3 months after the operation. Duplicate studies in 10 subjects demonstrated the reproducibility of the technique.

4613 SYNCHRONIZATION AND TIME SEQUENCE OF THE MOTILITY OF THE STOMACH, DUODENUM, BILIARY TRACT, AND PANCREAS. (Cze.) Klimov, P. K. (I. P. Pavlova Akademie ved SSSR, Leningrad, USSR). *Cesk. Gastroenterol. Vyz.* 29(3):176-183; 1975.

The coordination of motility of the stomach, duodenum, biliary tract, and pancreas of dogs was analyzed. During fasting, the organs underwent periodic transitions from relative rest to activity, with the electrographs showing only slow waves during rest and spike potentials during periodic hunger activity. A definite pattern of synchronization between the bioelectric activities of these organs which was temporarily disrupted (for 30-60 min) by pentagastrin administration (1-6 µg/kg, i.m.), was seen. At a dose of 1.0 µg/kg, pentagastrin had a brief (20-25 min) normalizing influence on disturbances in peristaltic activity and gastric evacuation following removal of the mucosa of the antral portion of the stomach. Removal of the duodenal mucosa resulted in a retarded evacuation, similar to so-called functional duodenal obstruction (duodenostasis). When administered to the dogs, the blood serum of human patients with this disorder induced inhibition of duodenal motility, widening of the duodenum, and a decrease in the amplitude of the slow electric waves. These findings, as well as data from the literature, are evidence of the union of two complex control systems, nervous and humoral, in a single regulatory mechanism.

4614 INTRALUMINAL PRESSURE OF THE SMALL INTESTINE OF THE UNANESTHETIZED DOG.

(Eng.) Tasaka, K.; Farrar, J. T. (Dept. Pharmacology, Faculty Pharmaceutical Sci., Okayama Univ., Okayama, Japan 700). *Pfluegers Arch.* 364(1):35-44; 1976.

The true pressures within the jejunun and ileum were determined in 14 unanesthetized dogs, and attempts were made to relate these pressures in one locus to those simultaneously occurring in adjacent and more distant loci. Intraluminal pressure recordings were performed in 14 unanesthetized dogs via a Mann-Bollman fistula by means of an air-filled balloon catheter system and a water-filled catheter system. Resting pressures in the proximal, middle, and distal jejunum averaged approximately 6 mm Hg above atmosphere, and no appreciable differences were noted between the different areas. The contraction time of simple, monophasic waves was fairly constant (approximately 1.0 sec in duration) and usually unrelated to the amplitude of the wave. Propulsion of intraluminal contents occurred in the absence of complex (type III) waves. A pressure wave in a proximal segment of the jejunum was temporally related to a wave occurring 5 cm distally. The mean intervals between the proximal and distal contractions were: 0.42 sec in the proximal jejunum, 0.74 sec in the middle jejunum, 1.56 sec in the distal jejunum, and 2.79 sec in the ileum. These time lags had a log normal distribution. The length of the physiologic segment in the jejunum of the dog varied from 1.0 to 8.0 cm and was usually 2-4 cm. The boundary of a segment varied from time to time, indicating that a segment is not a constant structure.

4615 A DOPAMINE RECEPTOR IN ESOPHAGEAL SMOOTH MUSCLE OF THE OPOSSUM.

(Eng.) de Carle, D. J.; Christensen, J. (Univ. Hosps., Iowa City, IA 52242). *Gastroenterology* 70(2):216-219; 1976.

The possibility that dopamine may play a role in nerve mediated "off" responses of esophageal body (EB) and relaxations of lower esophageal sphincter (LES) smooth muscle was examined in the isolated esophagus of the opossum. The effects of dopamine, epinine, and dopamine antagonists on EB and LES smooth muscle were also studied. Dopamine and epinine caused a dose-related fall in basal LES muscle tension and in amplitude of the EB muscle off response. The threshold dose for both was about 10^{-7} M, and maximal dose was about 10^{-4} M. At high concentrations, they also caused repetitive transient contractions of both LES and EB muscle after the period of inhibition. These effects were antagonized by haloperidol (10^{-5} M), and bulbocapnine (10^{-5} M), but were not influenced by propranolol (10^{-5} M) or phenoxybenzamine (10^{-5} M). Neither haloperidol nor bulbocapnine influenced responses to electrical field stimulation. Tetrodotoxin (10^{-7} M) abolished the responses to electrical field stimulation, but did not antagonize the effects of dopamine and epinine. EB and LES smooth muscle contain a dopamine receptor. It is unlikely that dopamine is involved in responses to electrical field stimulation.

4616 SYMPATHETIC NERVOUS CONTROL OF CAT ILEOCECAL SPHINCTER.

(Eng.) Pahlin, P.-E.; Kewenter, J. (Dept. Surgery III, Sahlgren's Hosp., 41345 Goteborg, Sweden). *Am. J. Physiol.* 231(2):296-305; 1976.

A perfusion method was designed to investigate the effects of stimulation of the splanchnic and lumbar colonic nerves on the ileocecal sphincter (ICS) of the cat. Splanchnic and lumbar colonic nerve stimulation at physiological frequencies (below 10-12 impulses/sec) elicited a contraction of the ICS concomitant with an inhibition of the motility of the adjacent parts of the small and large intestines. It appeared that the splanchnic and lumbar colonic nerves contract the ICS by a direct effect on the sphincter and not *via* a contraction of the intestine surrounding the sphincter. Guanethidine (3 mg/kg, i.v.) and phenoxybenzamine (5 mg/kg, i.v.), but not propranolol (1 mg/kg, i.v.), blocked the contraction of the ICS. It is suggested that the splanchnic and lumbar colonic nerves control the sphincter *via* an α-adrenergic mechanism. Inhibitory fibers were not found within the splanchnic or lumbar colonic nerves to the ICS. The excitatory response in the ICS elicited by adrenalin [0.1-2 γ/kg, intra-arterially (i.a.)], noradrenalin (0.9-7 γ/kg, i.v. or 0.1-4 γ/kg, i.a.), or phenylephrine (2-11 γ/kg, i.v. or 0.3-5 γ/kg, i.a.) infusion was completely blocked by phenoxybenzamine. Propranolol did not block the effect of these drugs on the ICS. An augmented response occurred, indicating unmasking of an excitatory α-receptor response by blockade of inhibitory β-receptors. Further support for these inhibitory β-receptors was provided by the finding that isoproterenol (3-14 γ/kg, i.v. or 2-10 γ/kg, i.a.) had a relaxing effect on the sphincteric muscle, an effect that was blocked by propranolol. To block the inhibitory effect on the small and large intestine elicited by splanchnic and lumbar colonic nerve stimulation, both phenoxybenzamine and propranolol had to be administered.

4617 EFFECTS OF CHOLINERGIC STIMULATION ON HUMAN ESOPHAGEAL PERISTALSIS.

(Eng.) Hollis, J. B.; Castell, D. O. (Naval Hosp., Portsmouth, VA 23708). *J. Appl. Physiol.* 40(1):40-43; 1976.

The effects of cholinergic stimulation on esophageal peristalsis were studied in 10 normal men. An intraesophageal transducer assembly was used to measure the dynamics of esophageal peristalsis before and after the i.v. injection of edrophonium chloride (80 mg/kg). Following edrophonium, there was a marked increase in the amplitude of esophageal peristalsis (from a mean ± standard error of

117 ± 13 mm Hg to 152 ± 17 mm Hg associated with a significant reduction in the velocity of esophageal peristalsis and a significant increase in the width and the time of appearance of the contraction wave following a swallow. Graded doses of edrophonium (20, 40, 80, and 160 μg/kg, i.v.) all resulted in significant increases in peristaltic amplitude, with the maximal response occurring at the two highest doses. Similar results were obtained with bethanechol (80 μg/kg, s.c.). The results indicate that cholinergic innervation is important in the regulation of esophageal motility.

4618 EFFECT OF INTRAVENOUS C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ AND INTRADUODENAL RICINOLEIC ACID ON CONTRACTILE ACTIVITY OF THE DOG INTESTINE.

(Eng.) Stewart, J. J.; Bass, P. (Univ. Texas Medical Sch. Houston, 6400 W. Cullen St., Houston, TX 77025). *Proc. Soc. Exp. Biol. Med.* 152(2):213-217; 1976.

The changes in ongoing digestive contractile activity after the intraduodenal administration of ricinoleic acid and the i.v. injection of the C-terminal octapeptide of cholecystokinin (CCK-OP) were studied in two dogs in which transducers had been implanted in the proximal jejunum, middle jejunum, terminal ileum, and proximal colon. CCK-OP produced a biphasic response when given as an i.v. bolus. At 50 ng/kg, there was an initial stimulation of digestive contractile activity in the proximal and middle jejunum, followed by a poststimulatory inhibition (PSI). At 500 ng/kg, there was a greater initial stimulation, followed by a longer PSI, and all areas of the intestine were affected (in contrast to the lower dose). Both repeated i.v. bolus injections of CCK-OP (50 ng/kg) and a single bolus injection of 500 mg of sodium ricinoleate produced the characteristic response of initial stimulation followed by poststimulatory inhibition. Repeated ricinoleic acid bolus injections produced increasingly diminished stimulatory responses. Atropine sulphate (100 μg/kg, s.c.) completely antagonized the motor effects of CCK-OP and ricinoleic acid. Hexamethonium (10 mg/kg, s.c.) only partially antagonized the effects of the ricinoleic acid. Because the motor actions of i.v. CCK-OP showed marked similarities to the responses evoked by the intraduodenal infusion of ricinoleic acid, the motor effects following infusion of a fatty acid into the proximal small intestine may result predominantly from the release of endogenous cholecystokinin.

4619 INTERACTION OF SOMATOSTATIN AND PENTAGASTRIN ON LOWER OESOPHAGEAL SPHINCTER PRESSURE (LESP) IN MAN.

(Eng.) Rosch, W.; Lux, G.; Schittenhelm, W.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 23 (3):209-212; 1976.

Because previous studies have suggested that somatostatin may be a hormone of the gastrointestinal tract, and because there are various interactions of gastrointestinal hormones in the control of lower esophageal sphincter pressure (LESP), the effect of somatostatin on basal- and gastrin-stimulated LESP was investigated in seven patients without diseases of the upper gastrointestinal tract. No change in LESP occurred after the administration of somatostatin (250 μg/hr, i.v.) under basal conditions, whereas the response to pentagastrin (0.6 μg/kg) was increased during the somatostatin infusion (67.0 ± 21.6 mm Hg) compared to the control period (47.0 ± 18.4 mm Hg, $p<0.01$). Somatostatin may act on LES inhibitory receptors that respond to pentagastrin.

4620 FURTHER STUDIES ON THE GANGLIONIC AND SMOOTH MUSCLE STIMULATING EFFECT OF POTASSIUM ON THE PERISTALTIC REFLEX OF THE GUINEA-PIG ISOLATED ILEUM.

(Eng.) Beleslin, D. B.; Samardzic, R. (Dept. Pharmacology, Medical Faculty, Beograd 11.000, P.O. Box 662, Yugoslavia). *Neuropharmacology* 14(10):769-777; 1975.

The effect of excess potassium ions on peristalsis was investigated in the isolated guinea pig ileum, and the mechanism of action was studied. Potassium (6.7-20.1 mM), acting from the serosal surface, produced two types of stimulating activity on the ileum, which was subjected to continuously raised intraluminal pressure. The first type of activity appeared in one-third of the experiments and consisted of full, strong and regular peristaltic waves. When potassium evoked this type of activity, the addition of hexamethonium (25.0-50.0 μg/ml), tetraethylammonium (25.0-50.0 μg/ml), dimethylphenylpiperazinium (2.5-10.0 μg/ml), or atropine (0.025-0.05 μg/ml) to the organ bath depressed the contractions of smooth muscles and caused small, irregular waves with incomplete relaxations between contractions. Eserine (0.002-0.003 μg/ml) potentiated this type of stimulating effect of potassium, while 0.33 mM potassium had no sensitizing action on the effect of 1.0 μg/ml of acetylcholine. In about two-thirds of the experiments, potassium caused the contraction of the longitudinal and circular muscle, which was followed by a few regular peristaltic waves. Thereafter, the peristalsis became irregular and was characterized by small and incoordinated waves with incomplete relaxation between contractions. 5-Hydroxytryptamine (0.25 μg/ml) and calcium (13.5-20.1 mM) applied to the serosal surface, transformed the small, irregular waves caused by potassium into regular peristaltic activity with full and strong peristaltic waves. Histamine (0.25-10.0 μg/ml) had no effect on this irregular activity. The stimulant effect of potassium did not remove the inhibitory action of ganglionic blocking agents, atropine, noradrenalin (1.0-5.0 μg/ml), adrenalin, 5-hydroxy tryptamine, or magnesium (1.4-2.7 mM), although it antagonized the peristaltic block caused by the addition of calcium to the organ bath. The interference of the direct effect of potassium on smooth muscle, with its action on myenteric ganglia, may cause small, irregular waves with incomplete relaxations between contractions. The results obtained with potassium and 5-hydroxytryptamine support the hypothesis that this amine acts on inhibitory neurones involved in the peristaltic reflex.

MOTILITY

4621 PHARMACOLOGICAL EFFECTS ON GASTRIC EMPTYING FOLLOWING LAPAROTOMY IN THE RAT.

(Eng.) Rentzhog, L.; Wikstrom, S. (Univ. Hosp., Uppsala, Sweden). *Acta Chir. Scand.* 141(7): 649-653; 1975.

The effect of metoclopramide, chlorpromazine, and neostigmine on postoperatively inhibited gastric emptying was investigated in male Sprague-Dawley rats. The gastrointestinal motility was analyzed 24 and 72 hr after laparotomy. Metoclopramide (3 mg/kg at 24 hr and 0.3 or 3 mg/kg at 72 hr), chlorpromazine (3 mg/kg at 24 hr and 0.1, 0.3, or 3 mg/kg at 72 hr), or neostigmine (0.1 mg/kg at 24 hr and 0.003, 0.01, or 0.1 mg/kg at 72 hr) was administered four times daily, s.c., beginning immediately after laparotomy. In the 24-hr series, 23.7% of the radioactive tracer was left in the stomach after 60 min. With metoclopramide, 11.9 ± 2.9% of the tracer was left in the stomach. There was no significant change in the rate of gastric emptying in rats given chlorpromazine and neostigmine (18.6 ± 4.0 and 21.8 ± 4.0, resp.) In the 72-hr series, there was no improvement in gastric emptying over the 24-hr series in controls and in animals given metoclopramide (0.3 mg/kg), chlorpromazine (all doses), or neostigmine (all doses). Metoclopramide (3 mg/kg) improved gastric emptying; only 6.8 ± 1.1% of the tracer remained in the stomach at 60 min. The results show that metoclopramide has an extremely marked accelerating effect upon gastric emptying following laparotomy.

4622 INFLUENCE OF SUBSTANCE P ON THE RESPONSE OF GUINEA PIG ILEUM TO TRANSMURAL NERVE STIMULATION.

(Eng.) Hedqvist, P.; von Euler, U. S. (Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 95(3):341-343; 1975.

The influence of synthetic substance P (SP) on the responses of the longitudinal muscle layer of the guinea pig ileum to transmural nerve stimulation and to acetylcholine (ACh) was studied. Field stimulation single pulses (2 Hz, 1 msec) elicited a brisk muscle contraction, which was abolished by atropine (3×10^{-7} M) and left unchanged by guanethidine (3×10^{-6} M), phentolamine (6×10^{-6} M), and propranolol (7×10^{-6} M), indicating activation of cholinergic nerves. SP (1.5×10^{-10} M) enhanced the contraction response to transmural nerve stimulation and often increased the basal tone of the preparation. Increasing the dose (7.5×10^{-10} M) caused a dose-dependent increase in basal tone, whereas the enhancement of the induced contractions remained the same or increased moderately. SP in the same concentrations only occasionally and weakly enhanced contractions induced by 2.2×10^{-8} M ACh; sometimes the contraction response to ACh even decreased in the presence of SP. The finding that SP more readily enhances ileal muscle contractions caused by nerve stimulation than by ACh administration suggests a prejunctional action of SP on cholinergic transmission.

SECRETION AND METABOLISM

4626 GASTROINTESTINAL METABOLISM OF CADMIUM IN EXPERIMENTAL IRON DEFICIENCY.

(Eng.) Valberg, L. S.; Sorbie, J.; Hamilton, D. L. (Dept. Medicine, Univ. Western Ontario, London, Ontario N6A 5A5, Canada). *Am. J. Physiol.* 231(2):462-467; 1976.

Studies were carried out in male C57BL/6 mice to further investigate the role of the gastrointestinal tract in cadmium metabolism and to compare the gastrointestinal handling of cadmium with iron. In addition the effect of iron deficiency on the absorption and rate of excretion of a p.o. dose of cadmium, the excretion of an s.c. dose of cadmium, and the distribution of cadmium throughout the gastrointestinal tract, after either a p.o. or a parenteral dose of cadmium, was determined. The average gastrointestinal uptake 4 hr after an intragastric dose of 400 nmol of labeled cadmium chloride ($^{109}CdCl_2$) in iron-deficient mice (fed a diet containing <2 mg iron/kg for 8 weeks) was 25%, which was significantly greater than the 16% uptake observed in animals fed a normal diet. More cadmium entered the body of the former group (3.8%), than the latter (2%, $p<0.05$). Between 4 and 72 hr, gastrointestinal radioactivity declined without further increase in body activity; more radiocadmium remained in the duodenum of iron-deficient than normal animals ($p<0.05$). The radiocadmium sequestered in the duodenum was bound to a protein with a molecular weight of about 12,000. After the s.c. injection of radiocadmium (200 nmol 0.3 μCi $^{109}CdCl_2$), the rate of excretion of radioactivity from the body was similar in iron-normal and iron-deficient mice; a greater proportion of the injected dose accumulated in the duodenum of the iron-deficient animals ($p<0.05$). The intestinal adaptive response to iron deficiency may enhance cadmium toxicity, whereas sequestration and subsequent excretion of cadmium by the intestinal mucosa serves to protect the body against toxic effects. The duodenum, particularly in iron-deficient mice, is especially vulnerable to the toxic effects of cadmium.

SECRETION AND METABOLISM

Stomach

4632 COMPARISON OF AMINO ACIDS BATHING THE OXYNTIC GLAND AREA IN THE STIMULATION OF GASTRIC SECRETION. (Eng.) Konturek, S. J.; Tasler, J.; Obtulowicz, W.; Cieszkowski, M. (Medical Acad., Cracow, Poland). *Gastroenterology* 70(1):66-69; 1976.

The ability of L- and D-isomers of amino acids bathing the oxyntic gland area to stimulate acid secretion was compared in four conscious dogs with Heidenhain pouch (HP), gastric fistula (GF), and pancreatic fistula (PF). Acid outputs from HP were determined by an intragastric titration method when amino acid solutions were perfused into HP at various concentrations, pH values, and distension pressures. The L-isomers of four essential amino acids, histidine, leucine, tryptophan, and phenylalanine, stimulated acid secretion, whereas D-isomers of these amino acids were completely inert in this respect. L-histidine among essential amino acids and glycine among nonessential amino acids exhibited the strongest stimulation of acid outputs, reaching 52 and 40%, resp. of the maximal response to histamine. Decreasing the pH of L-histidine solution perfused into HP in sequential order from 5.0 to 1.0 resulted in a stepwise reduction of acid output, falling at pH 1.0 to about 40% of the peak response achieved at pH 5.0. Local irrigation of HP by 2% xylocaine and the i.v. infusion of atropine (100 μg/kg/hr) or metiamide (2.9 mg/kg/hr) reduced, but did not abolish, HP response to chemical stimulation and the pH dependency of this response. It is concluded that only L- and not D-isomers of amino acids bathing the oxyntic gland area stimulate acid secretion by a local, gastrin-independent mechanism sensitive to distension pressure and pH.

4633 AN ELECTRON MICROSCOPIC STUDY OF THE DISTRIBUTION OF SODIUM IN NORMAL, PENTAGASTRIN-STIMULATED AND SECRETIN-INHIBITED FUNDIC MUCOSA OF THE STOMACH OF THE RAT. (Eng.) Kalahanis, N. G.; Nyhus, L. M.; Das Gupta, T. K. (Abraham Lincoln Sch. Medicine, Univ. Illinois, Chicago, IL). *Surg. Gynecol. Obstet.* 143(2):263-269; 1976.

Sodium localization was studied by electron microscopy in normal (untreated), pentagastrin (125 µg/kg, s.c.)-stimulated, or secretin (1 U/100 g, s.c.)-inhibited stomachs of 24 male Sprague-Dawley rats. Pieces of fundic mucosa were fixed either by perfusion or by immersion in an unbuffered osmium tetroxide-potassium pyroantimonate mixture (pH= 7.6). Both fixation methods gave comparable results. In the untreated tissue, sodium pyroantimonate crystals were mainly seen in and around the collagen fibers in the interstitium, and to a lesser extent, in the basal and lateral plasma membranes of the epithelial cells. No significant differences occurred in the secretin-inhibited tissue. In contrast, in the pentagastrin-stimulated rats, an increase in the amount of precipitate and a redistribution of the sodium pyroantimony deposits occurred; a larger amount of precipitate was seen toward and on the basal and lateral cell membranes, and the number of capillary pinocytotic vesicles containing the reaction product was greater. The amount of precipitate in the capillary lumen was also larger. The pyroantimonate technique seems promising for studying the mechanism of sodium transport in the gastric mucosa.

4634 EFFECT OF GASTRIN ON GASTRIC MUCOSAL CELL PROLIFERATION IN MAN. (Eng.) Hansen, O. H.; Pedersen, T.; Larsen, J. K.; Rehfeld, J. F. (Bispebjerg Bakke 33, DK-2400 Copenhagen NV, Denmark). *Gut* 17(7):536-541; 1976.

The effect of exogenous gastrin on cell proliferation kinetics in the gastric mucosa was studied in three normal subjects, and the relationship between the kinetic parameters and the serum gastrin concentrations was determined in 46 patients with different gastric diseases. Endoscopic biopsies were labeled *in vitro* with ^{3}H-thymidine, and autoradiographs were prepared. The percentage of DNA-synthesizing cells in the progenitor cell region was estimated. Sixteen hours after beginning the infusion of a large dose of pentagastrin (10 µg/kg/hr, i.v.), a marked increase in the labeling index occurred in the fundic mucosa of the normal subjects. The antral mucosa was not responsive to this effect. In the same subjects, infusion of a low dose of synthetic human gastrin I (8 ng/kg/min) did not affect the rate of cell proliferation, either in the fundic or in antral mucosa. In the patients with different gastric disease (13 with normal stomachs, 7 with duodenal ulcer, 5 with prepyloric ulcer, 6 with gastric ulcer, 5 with gastric cancer, and 10 with atrophic gastritis), no correlation between the serum gastrin concentrations and the labeling indices was found. The results suggest that the human fundic mucosa is responsive to a trophic action of pentagastrin. If it exists, a physiological action of gastrin as a trophic hormone for human gastric mucosa must be considerably more complex than previously believed.

4635 EFFECTS OF ETHANOL ON THE SECRETION AND MUCOSAL BLOOD FLOW OF A DENERVATED GASTRIC POUCH IN THE DOG. (Eng.) De Saint Blanquat, G.; Lamboeuf, Y.; Derache, R. (Groupe de Recherche sur la Toxicite des Aliments et des Boissons INSERM U.87, 2, rue Francois Magendie, 31.400 Toulouse, France). *Eur. J. Pharmacol.* 34(1):219-222; 1975.

Mucosal secretion and blood flow were measured in Heidenhain pouches in four dogs after the administration of ethanol (0, 0.25, 0.50, 1, and 2 g/kg, p.o.). Free acidity (1.13-1.96 mEq/hr), total acidity (1.64-2.79 mEq/hr), pepsin (2.73-2.93 mg/hr), and gastric mucosal blood flow (GMBF, 0.630-0.890 l/hr) were increased linearly at ethanol doses up to 1 g/kg; these levels were also raised at the 2 g/kg dose, but this level was always lower than the 1 g/kg dose. The GMBF to secretion ratio did not change with the dose, while the circulating blood volume required for the secretion of 100 µg of pepsin did. Significant dose-response regression lines ($p<0.05$) were observed for all secretory parameters, except pepsin, when the 2 g/kg dose was disregarded; the dose/GMBF regression was the most significant ($p<0.01$). The volume secreted and the acidity were correlated with GMBF, although pepsin secretion was not. The intragastric administration of 5 ml of water/kg was not followed by any secretion from the pouch, demonstrating that the distension induced by this volume was not sufficient to induce gastric secretion. The fact that the 2 g/kg dose of ethanol did not produce as marked a hypersecretory effect as the lower doses may be explained by previously reported studies, which showed that high ethanol doses modify ionic fluxes in the gastric mucosa.

4636 EFFECTS OF ETHANOL ON THE CYCLIC AMP SYSTEM OF THE DOG GASTRIC MUCOSA. (Eng.) Puurunen, J.; Karppanen, H.; Kairaluoma, M.; Larmi, T. (Dept. Pharmacology, Univ. Oulu, SF-90 220 Oulu 22, Finland). *Eur. J. Pharmacol.* 38(2):275-279; 1976.

The effect of ethanol on the cyclic AMP system of the canine fundic mucosa was studied *in vitro* to determine the mechanism by which ethanol influences gastric acid secretion. Ethanol (2.5%) increased the gastric mucosal content of cyclic AMP, whereas 10 and 20% ethanol decreased the mucosal content. The adenylate cyclase activity was increased by ethanol at 2.5 and 5%, but 10% ethanol did not significantly affect it. The activity of cyclic AMP phosphodiesterase was inhibited by ethanol in a competitive manner, the K_i value being 9×10^{-2} M, corresponding to an ethanol concentration of 5%. The increase in the gastric mucosal content of cyclic AMP, induced by low concentrations of ethanol, is apparently due to the stimulation of adenylate cyclase and inhibition of phosphodiesterase. Changes in the phosphodiesterase or adenylate cyclase activities do not explain the decrease of the mucosal content of cyclic AMP by higher concentrations of ethanol. Other studies have suggested that this decrease might be secondary to changes in the formation of prostaglandins.

4637 SUPPRESSION OF GASTRIC SECRETION AND SERUM GASTRIN BY GASTRIN ANTIBODY. (Eng.)

Villar, H. V.; Watayou, T.; Booth, R. A. D.; Rayford, P. L.; Reeder, D. D.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Surg.* 131(1):64-68; 1976.

To elucidate the mechanism of antigastrin antibody (Ab_G)-induced gastrin inactivation *in vivo*, 14 dogs received varying doses of Ab_G, i.v. After a single dose of Ab_G (0.07 ml/kg), circulating gastrin levels could not be measured for as long as 47 days. Gastric secretion in response to food was not diminished by antigastrin antibody doses as high as 0.07 ml/kg daily for 10 days. Larger doses (0.2 and 0.4 ml/kg) produced a temporary reduction in gastric-stimulated gastric acid secretion. Mucosal levels of gastrin in the antrum, fundus, and duodenum were greatly increased (25,000-28,700, 102-176, and 302-378 ng/g, resp.) 10 days after injection of Ab_G (0.03 or 0.07 ml/kg). The levels in controls receiving normal rabbit serum were 9,200-16,400, 15.2-56, and 184-196 ng/kg in antrum, fundus, and duodenum, resp. The therapeutic use of antigastrin antibody to control gastric secretion does not seem feasible because of the scarcity of Ab_G and because large doses are required to obtain an only temporary effect.

4638 FURTHER EVIDENCE FOR AN INTESTINAL PHASE HORMONE THAT STIMULATES GASTRIC ACID SECRETION.

(Eng.) Orloff, M. J.; Charters, A. C., III; Nakaji, N. T. (Sch. Medicine, Univ. California, San Diego, CA 92110). *Surgery* 80(2):145-154; 1976.

An attempt was made to isolate the hormone responsible for the intestinal phase of gastric acid secretion. Extracts (110) of hog intestinal mucosa, each representing the yield from about 3,000 hogs, were prepared by a method for isolating small peptides that involved heating, absorption on diethylaminoethylcellulose, and acid precipitation. All extracts (2 mg protein, i.v., over 30 min) stimulated gastric acid secretion (basal level=1.00 ± 0.09; extract-stimulation=6.24 ±0.56, $p<0.001$) in gastric fistula from male Long-Evans rats; 56 extracts were highly active (greater than 50% increase in acid output above basal level in at least 60% of rats). Increasing doses of extract (0.002, 0.02, 0.2, 2.0, 5.0, and 10.0 mg, i.v., over 30 min) stimulated increasing acid production according to a regular dose-response relationship. Twelve highly active extracts were tolerated without side effects when infused into dogs with Heidenhain pouches and produced a mean 22-fold increase in acid output above basal. The gastrin content of 73 extracts measured by radioimmunoassay, averaged 5.80 ng per rat dose of extract, which is approximately 1/500 of the minimal stimulating dose of hog gastrin. No extract contained sufficient gastrin to produce an acid secretory response. Administration of the extract, together with a maximal stimulating dose of pentagastrin (600 μg, i.v.), in rats significantly augmented the maximal acid secretory response. The gastric secretory responses to the infusion of 27 highly active intestinal mucosal extracts (2 mg) into the inferior vena cava and into the portal vein were compared in rats with acute gastric fistulas. Systemic infusion produced a mean 2-hr gastric acid output of 9.56 ± 1.11 μEq, whereas portal venous infusion produced a secretion of only 2.48 ± 0.66 μEq, reflecting substantial inactivation of extract by the liver. There was marked inactivation of pentagastrin (2 or 20 μg) by the liver, but no hepatic inactivation of hog gastrin (20 μg). It is concluded that the extract had all of the known physiologic properties of the intestinal phase hormone and probably contained the intestinal phase hormone.

4639 EFFECT OF METIAMIDE ON ACID SECRETION FROM ISOLATED KITTEN FUNDIC MUCOSA. (Eng.)

Tepperman, B. L.; Schofield, B; Tepperman, F. S. (Div. Medical Physiology, Univ. Calgary, Calgary, Alberta T2N 1N4, Canada). *Can. J. Physiol. Pharmacol.* 53(6):1141-1146; 1975.

The effect of metiamide on acid secretion in the isolated kitten fundic mucosa was investigated *in vitro*. Two separate segments of stripped fundus were bathed in a Krebs-Henseleit solution to which pentagastrin (8.1 x 10^{-7} M), histamine (1.6 x 10^{-5} M), or acetylcholine chloride (10^{-4} M) had been added. Metiamide was injected into the bathing solution 30 min after the gastric excitant; the final bath concentration was 5.0 x 10^{-3} M. Metiamide suppressed the spontaneous secretion observed in five mucosal preparations; the mean response level in controls was 2.06 ± 0.16 μEq/cm^2/hr, and in test animals it was 0.59 ± 0.17 μEq/cm^2/hr ($p<0.05$). Metiamide strongly inhibited the acid response of the kitten mucosa to histamine, and to a lesser extent, to pentagastrin. Metiamide did not alter the response to repeated stimulation with acetylcholine. The results do not support the previously published conclusion that there is a general, nonspecific action of metiamide consequent upon blood flow effects.

4640 THE EFFECT OF METIAMIDE, AN H_2-RECEPTOR ANTAGONIST, IN THE PREVENTION OF EXPERIMENTAL STRESS ULCERS.

(Eng.) Safaie-Shirazi, S.; Foster, L. D.; Hardy, B. M. (Univ. Hosp., Iowa City, IA 52242). *Gastroenterology* 71(3):421-425; 1976.

Because of evidence that metiamide strongly inhibits gastric acid secretion, the hypothesis that metiamide will prevent bile salt-induced stress ulcers during hemorrhagic shock was tested. Forty dogs were bled and maintained for 4.5 hr at a mean blood pressure of 40-50 mm Hg. In group A, 10 dogs received 300 mg of metiamide p.o. 45 min before bleeding, and 10 dogs received normal saline. The pylorus was occluded before bleeding, and 10 ml of 15 mM bile salt were instilled into the stomach and aspirated at the end of 4.5 hr. The animals were killed after 48 hr; no ulcers were seen in the stomachs of dogs treated with metiamide. Sixty percent of the dogs in the untreated group developed multiple gross ulcers. In group B, the effect of metiamide on the disappearance rate of H^+ ions was measured by the instillation of 50 mM HCl plus 15 mM bile acid. No difference was noted in the rate of H^+ ion disappearance between metiamide-treated and control dogs. In five normotensive dogs, the rate of H^+ ion disappearance was identical before and after treatment with metiamide. Metiamide was effective in preventing stress ulcer in this experimental model, probably due to its inhibitory effect on H^+ ion secretion.

4641 INHIBITION OF GASTRIC ACID SECRETION IN DOGS BY NEUROTENSIN.

(Eng.) Andersson, S.; Chang, D.; Folkers, K.; Rosell, S. (Dept. Pharmacology, Karolinska Institutet, 104 01 Stockholm 60, Sweden). *Life Sci.* 19(3):367-370; 1976.

The action of synthetic neurotensin on gastric acid secretion was studied in three dogs with gastric pouches to elucidate its possible physiological action. After approximately 30 min of neurotensin infusion (50 ng/kg/min, i.v.), pentagastrin-stimulated (1-1.5 μg/kg/hr, i.v.) gastric acid secretion was considerably inhibited. This inhibition reached maximal levels 60-90 min after the start of infusion, and the acid output returned to normal 60 min after the end of the infusion. In contrast, there was no inhibition of histamine-induced (1 mg/hr, i.v.) acid secretion. Neurotensin is a potent, selective, gastric secretory inhibitor.

4642 EFFECT OF FIFTY PERCENT SMALL BOWEL RESECTION ON GASTRIC SECRETORY FUNCTION IN RHESUS MONKEYS.

(Eng.) Moossa, A. R.; Hall, A. W.; Skinner, D. B.; Winans, C. S. (Pritzker Sch. Medicine, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637). *Surgery* 80(2):208-213: 1976.

To investigate the relation between gastric hypersecretion and alteration of gastric function by disease or bowel resection, basal acid output (BAO) and histamine-stimulated acid output (MAO) were studied in 11 fasting rhesus monkeys before, and at 6 weeks, and 6 months after 50% distal small bowel resection. Serum gastrin and gastric inhibitory polypeptide (GIP) were assayed in eight monkeys. Highly significant increases were seen in BAO (0.37 ± 0.05 - 1.73 ± 0.37 mEq/hr; $p<0.005$) and MAO (1.7 ± 0.22-3.21 ± 0.45 mEq/hr; $p<0.01$) at 6 weeks. These levels persisted at 6 months. The ratio BAO to MAO increased from 0.231 to 0.505 at 6 weeks and to 0.61 by the end of the study. A significant rise was noted in the levels of both fasting serum gastrin (99.5 ± 14-148.4 ± 20 pg/ml, $p<0.05$) and GIP (664 ± 111-1,132 ± 88 pg/ml, $p<0.01$) during the early phase. By 6 months, the levels of both hormones had fallen and were not significantly different from the control values. It is concluded that 50% small bowel resection causes a persistent increase in gastric acid secretion with no corresponding sustained change in serum gastrin or GIP.

4643 REFLUX GASTRITIS: THE CONSEQUENCES OF INTESTINAL JUICE IN THE STOMACH.

(Eng.) Robbins, P. L.; Broadie, T. A.; Sosin, H.; Delaney, J. P. (Univ. Minnesota Health Sciences Center, 412 S.E. Union St., Minneapolis, MN 55455). *Am. J. Surg.* 131(1):23-29; 1976.

The consequences of the diversion of duodenal contents through the stomach was studied in six dogs to further investigate whether chronic gastritis is induced by exposure of the stomach mucosa to intestinal contents. The pylorus in six adult female mongrel dogs was excised, separating antrum from duodenum, and the distal stump was oversewn. The duodenum was divided again, proximal to the ligament of Treitz. The distal cut end was then anastomosed to the gastric antrum, and the proximal segment was drained end-to-side into the high gastric corpus. A year or more later, the mean gastritis grade for the corpus increased from approximately 2.7 to 6.0; in the antral mucosa, the mean score was 4.6 before the operation, and 7.5 at 8-24 months after the operation. Increases in parietal cell density were seen in four of six animals, and there was an enhanced maximal acid secretory capacity in three of six animals. No significant changes were seen in insulin-stimulated (0.5 U/kg) acid secretion, insulin-stimulated pepsin secretion, antral gastrin levels, or G cell numbers. It is concluded that chronic exposure of the intact stomach to duodenal contents results in gastritis and an amplified gastrin response to food.

4644 THE EFFECTS OF SEMISTARVATION AND PARENTERAL NUTRITION ON THE GASTRIC MUCOSA OF RATS.

(Eng.) Oram-Smith, J. C.; Rosato, E. F. (Univ. Pennsylvania Sch. Medicine, 3400 Spruce St., Philadelphia, PA 19104). *Surgery* 79(3):306-309; 1976.

The effects of semistarvation and of i.v. nutrition on the gastric mucosa were studied in 24 male Wistar rats (250-350 g) placed on one of three dietary regimens: group I, standard rat chow *ad libitum* (adequate p.o. intake); group II, 50 cm^3/day of a hyperalimentation solution containing 30% glucose plus 5% amino acids (adequate i.v. intake); and group III, 50 cm^3/day of 5% glucose (semistarved). After 7 days, gastric mucosal ion fluxes were measured following the gastric instillation of two gastric wash solutions, one containing HCl, and the other containing HCl and sodium taurocholate. The volume of gastric secretion was decreased in groups II and III (1.0-1.2 ml/hr and 0.7-0.8 ml/hr, resp.), in comparison to group I (1.9-2.1 ml/hr). The net negative hydrogen flux was increased in groups II and III (H/polyethylene glycol marker = -1.3 to -1.8 and -3.3 to -6.4 mEq/g, resp.) over group I (7.0 mEq/g). The net negative H^+ flux in group III was significantly increased over group II ($p<0.01$), but no difference in the volume of secretion was seen. Only group III demonstrated a difference in H^+ flux after the addition of sodium taurocholate (before: -3.3, after: -6.4; $p<0.005$). Gastric lesions were significantly increased in group III (gastric score, 18), as compared to groups I and II (score, 6 in both cases). There was no difference in sodium flux in the three dietary groups. The movement of lithium was independent of the movement of H^+ and did not serve as an indicator for H^+ back diffusion. The only group to demonstrate a negative lithium flux (-0.01/polyethylene glycol marker after the addition of taurocholate was group III. The results suggest that semistarvation renders the gastric mucosa more susceptible to injury, and that adequate parenteral nutrition alone protects against these effects.

SECRETION AND METABOLISM

Pancreas

4652 ACTION OF CHOLECYSTOKININ, CHOLINERGIC AGENTS, AND A-23187 ON ACCUMULATION OF GUANOSINE 3':5'-MONOPHOSPHATE IN DISPERSED GUINEA PIG PANCREATIC ACINAR CELLS. (Eng.) Christophe, J. P.; Frandsen, E. K.; Conlon, T. P.; Krishna, G.; Gardner, J. D. (Univ. Brussels Medical Sch., 1000 Brussels, Belgium). *J. Biol. Chem.* 251(15):4640-4645; 1976.

The effects of the COOH-terminal octapeptide of cholecystokinin (CCK-OP) and related peptides, as well as carbamylcholine, on the accumulation of cyclic guanosine monophosphate (cGMP) were studied in dispersed acinar cells from Hartley guinea pig pancreas. The effects of the agents on the outflux of ^{45}Ca from these cells was also studied. Finally, the effects of the divalent cation ionophore A-23187 on these two processes were tested. CCK-OP and carbamylcholine each increased calcium outflux, cellular cGMP, and amylase secretion in the dispersed acinar cells. Following addition of CCK-OP or carbamylcholine, cellular cGMP increased as early as 15 sec, became maximal after 1-2 min, and decreased steadily during the subsequent incubation. For both CCK-OP and carbamylcholine, there was close agreement between the dose-response curve for stimulation of calcium outflux and that for increase of cellular cyclic GMP. With CCK-OP, an effect on both functions could be detected at 10^{-10} M, and maximal stimulation occurred at 3×10^{-8} M. With carbamylcholine, an effect on both functions could be detected at 10^{-5} M, and maximal stimulation occurred at 3×10^{-3} M. Atropine (10^{-9}-10^{-5} M) inhibited stimulation of both cGMP and calcium outflux by carbamylcholine, but not by CCK-OP. Stimulation of calcium outflux or cellular cGMP by CCK-OP or carbamylcholine did not require extracellular calcium, since stimulation occurred in a calcium-free, ethylene glycol bis (β,β-aminoethyl ether) *N,N'*-tetraacetic acid (EGTA)-containing solution. A-23187 (5×10^{-6} M) increased bidirectional fluxes of calcium, cellular cGMP, and secretion of amylase from dispersed pancreatic acinar cells. Like CCK-OP and carbamylcholine, the ionophore stimulated calcium outflux and cellular cGMP in a calcium-free, EGTA-containing solution. These results suggest that in pancreatic acinar cells, the initial step in the sequence of events mediating the action of ionophore, as well as that of CCK-OP and carbamylcholine, is stimulation of calcium outflux, and that this stimulation then increases cellular cGMP.

4653 PANCREATIC GASTRIN IN FOETAL AND NEONATAL RATS. (Eng.) Larsson, L.-I.; Rehfeld, J. F.; Sundler, F.; Hakanson, R. (Inst. Medical Biochemistry, Univ. Aarhus, Aarhus, Sweden). *Nature* 262(5569):609-610; 1976.

The cell type in which pancreatic gastrin is stored and the ontogeny of the rat pancreatic gastrin cell were studied. A large number of gastrin antisera, most of which were specific for the C-terminal bioactive sequence of gastrin-17, were tested on both unfixed and formaldehyde-fixed tissue. All antisera reacted with antral gastrin cells, but not with A_1 cells, suggesting that if gastrin-like peptides occur in the pancreatic A_1 cells, they must be devoid of the bioactive C-terminal sequence. At the 18th gestational day (the earliest stage studied), pancreatic gastrin-immunoreactive cells were seen both in islets and scattered among exocrine cells. The number of these cells increased up to day 4 after birth, when it slowly began to decrease. Only a few pancreatic gastrin cells, restricted to the duct epithelium, were observed in 12- to 20-day-old rats, and in rats older than 20 days, gastrin cells were almost never observed in the pancreas. A pattern similar to that in the pancreas was seen in the duodenum. Cells with an ultrastructure indistinguishable from that of the presumed gastrin cells (G cells) of rat antral mucosa were detected in the antral and duodenal mucosa and in the pancreas of 4-day-old neonatal rats. The distribution pattern and number of G cells were in agreement with that of the gastrin-immunoreactive cells. Gastrin immunoreactivity was observed in the duodenum (10.5 μEq synthetic human gastrin-17/g wet weight tissue) and pancreas (3.2 μg/g) of 4-day-old rats, while the level of antral gastrin was lower (0.9 μg/g). The concentration of antral gastrin in the adult rat was 18.4 μg/g. Gel-permeation chromatography revealed that gastrin immunoreactivity from the pancreas of 4-day-old rats eluted in the same pattern as gastrin from the antral mucosa of adult rats. The results indicate that gastrin cells appear first in the duodenum and pancreas, and only later in the antrum.

4654 EFFECT OF GASTRIN ON PANCREATIC ENZYME SECRETION AND GALLBLADDER EMPTYING IN MAN. (Eng.) Valenzuela, J. E.; Walsh, J. H.; Isenberg, J. I. (Univ. Chile Sch. Medicine, Casilla 6539, Santiago 4, Chile). *Gastroenterology* 71(3):409-411; 1976.

The effect of unsulfated synthetic human little gastrin (HG-17-I) on pancreatic secretion and gallbladder emptying was assessed in six normal men. During continuous gastric and duodenal aspiration, the subjects were given on different days either HG-17-I (7, 20, 60, 180, and 540 pmol/kg/hr over 40 min as a constant i.v. infusion), cholecystokinin (0.1, 0.3, and 0.9 U/kg/hr, i.v., over 40 min), or 238 pmol/kg (500 ng/kg) of HG-17-I as a rapid i.v. injection. Significant increases in trypsin output and bilirubin output above basal levels occurred during the infusion of both peptides. During HG-17-I infusion, the highest trypsin output (2.08 ± 0.22 Karmen U/10 min) and bilirubin output (4.66 ± 0.61 mg/10 min) occurred during the 60 pmol/kg/hr dose, whereas highest acid output occurred during the 540 pmol/kg/hr dose. Rapid i.v. injection of HG-17-I produced a prompt and significant rise in trypsin, bilirubin, bicarbonate, and acid outputs. It is concluded that HG-17-I produced significant pancreatic enzyme secretion and gallbladder emptying at doses that are submaximal for acid secretion, suggesting that this may be a physiological effect of gastrin.

4655 CELLULAR CYCLIC NUCLEOTIDES AND ENZYME SECRETION IN THE PANCREATIC ACINAR CELL. (Eng.) Haymovits, A.; Scheele, G. A. (Rockefeller Univ., New York, NY 10021). *Proc. Natl. Acad. Sci. USA* 73(1):156-160; 1976.

To investigate the roles of cyclic AMP (cAMP) and cyclic guanosine monophosphate (cGMP) in stimulus-secretion coupling in pancreatic acinar cells, the levels of these nucleotides were measured by radioimmunoassay in guinea pig pancreatic lobules incubated *in vitro*, during basal or stimulated secretion. Stimulation with optimal concentrations of carbamylcholine (carbachol, 10^{-5} M), pancreozymin (0.1 U/ml), and cerulein (10^{-9} M) resulted in a sharp rise in cGMP levels, from 5 to more than 20 times that of basal levels. cAMP levels did not change significantly. cGMP increases were maximal at 2 min, and then subsided by 4-7 min to a plateau about two to three times that of basal level. This plateau was maintained for the duration of the secretagogue stimulus. Removal of the carbachol stimulus resulted in a rapid decrease in cGMP levels to that of the basal state. The cellular cGMP levels observed within the first 2 min of stimulation correlated closely with the dose of carbachol and the secretory response. Atropine (10^{-4} M) blocked the cGMP elevation due to carbachol, but not due to pancreozymin, while carbonyl cyanide *m*-chlorophenyl hydrazone (10^{-4} M) blocked the response to both secretagogues. Similar results were obtained using rabbit pancreatic lobules incubated *in vitro*. High concentrations (10^{-2}-10^{-3} M) of the dibutyryl and 8-bromo analogues of both nucleotides were effective, although suboptimal, secretagogues. With the cAMP analogues, the secretory response was associated with an increase in endogenous cGMP levels, similar

LIBRARY U. C.

to that observed during suboptimal carbachol stimulation. These findings suggest that cGMP may be an intracellular mediator in the process of stimulus secretion coupling in the acinar cell of the exocrine pancreas.

4656 CYCLIC AMP IN PANCREATIC ACINAR CELLS: EFFECTS OF GASTROINTESTINAL HORMONES.

(Eng.) Gardner, J. D.; Conlon, T. P.; Adams, T. D. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Gastroenterology* 70(1):29-35; 1976.

The effects of natural and synthetic gastrointestinal hormones, as well as other agents, on cellular cyclic AMP levels were investigated in acinar cells isolated from guinea pig pancreas. In the presence of theophylline (5 mM), secretin (10^{-7}), and vasoactive intestinal peptide (VIP, 10^{-6} M) each increased cyclic AMP in the acinar cells; secretin plus theophylline produced a fivefold increase in cyclic AMP, while the increase produced by VIP was 33% less. Without theophylline, neither peptide altered cellular cyclic AMP. Glucagon (10^{-5} M) neither stimulated cellular cyclic AMP nor inhibited the stimulation produced by secretin or by VIP. Other agents that did not increase cellular cyclic AMP were cholecystokinin (10^{-5} M), the carboxyl-terminal octapeptide of cholecystokinin (10^{-5} M), synthetic gastrin I or II (10^{-5} M), bovine pancreatic polypeptide (10^{-5} M), carbamylcholine (10^{-4} M), and prostaglandin E_1 (10^{-3} M). Neither carboxyl-terminal octapeptide nor gastrin I altered the stimulation of cellular cyclic AMP produced by secretin or VIP. With natural secretin, a significant increase in cellular cyclic AMP was detected at concentrations as low as 3 x 10^{-10} M, and maximal stimulation occurred at 10^{-8} M. VIP was approximately 1% as potent as natural secretin, and maximal concentrations of secretin plus VIP increased cellular cyclic AMP to the same value as that obtained with a maximal concentration of secretin alone. These results indicate that pancreatic acinar cells possess receptors for VIP and for secretin that do not interact with glucagon.

4657 EXOCRINE FUNCTION OF PANCREAS IN CHRONIC HYPOCALCEMIA. STUDIES IN PARATHYROIDECTOMIZED RATS.

(Ger.) Heidbreder, E.; Kappel, W.; Heidland, A. (Medizinische Universitatsklinik, D-87 Wurzburg, Josef-Schneider-Str. 2, W. Germany). *Res. Exp. Med. (Berl.)* 165(2):93-99; 1975.

To study the effect of chronic hypocalcemia on the exocrine pancreatic function, parathyroidectomy was performed on 9 Wistar rats; 10 rats served as controls. Fourteen to 21 days after parathyroidectomy, the amount of pancreas secretion was measured, and the flow rate calculated. Total calcium, alpha amylase, urea nitrogen, blood chemistry, bicarbonate, and hemoglobin were determined. Changes after chronic calcium depression were less marked then in acute hypocalcemia. The flow rate was higher in the parathyroidectomized rats (7.9 ± 0.5 µl/min after 50 min, decreasing to 6.9 µl/min after 2 hr) compared to the controls (6 µl/min, decreasing to 5.6 ± 0.9 µl/min). The difference was statistically significant ($p<0.01$). Total pancreatic calcium secretion, if related to the flow rate, showed very similar curves for both groups. Calcium concentration values were significantly lower ($p<0.01$) in the parathyroidectomized rats, but showed no statistically significant difference compared to the controls, if related to the flow rate. Alpha amylase concentration and secretion were initially increased, but not altered altogether. Although the results of this study indicate no significant change of exocrine pancreatic function in chronic hypocalcemia, it could not be determined if and when a continued extracellular calcium decrease would lead to exocrine insufficiency *in vivo*.

4658 ATROPINE-INDUCED INHIBITION OF THE ENHANCED CCK RELEASE OBSERVED IN ALCOHOLIC DOGS.

(Eng.) Voirol, M.; Bretholz, A.; Levesque, D.; Laugier, R.; Tiscornia, O.; Sarles, H. (Hopital universitaire, Unite de Gastroenterologie, Medecine I, Boulevard de la Cluse, Geneve, Switzerland). *Digestion* 14(2):174-178; 1976.

Experiments were carried out to determine whether the previously observed increased pancreatic secretory response to oleic acid in alcoholic animals is caused by a cholinergic nerve-mediated increase in the release of cholecystokinin (CCK). Two dogs with a Thomas cannula were given ethanol (2 g/kg/day) intragastrically for 3 yr, and four nonalcoholic dogs with a cannula were used as controls. The increased secretory response in the alcoholic dogs was confirmed by these experiments. Oleic acid (20 ml) was instilled intraduodenally 20 min after a secretion plateau was reached during secretin infusion (1 CU/kg/hr, i.v.). When atropine (0.75 mg/kg/hr) was added to the infusion, the protein output in both alcoholic and nonalcoholic dogs was significantly decreased. However, the difference in output between the alcoholic and nonalcoholic dogs, seen after oleic acid administration when secretin was infused alone, was abolished by atropine; the oleic acid-elicited peak protein response (35 mg/20 min) was identical in alcoholic and nonalcoholic animals. The increased release of CCK in alcoholic animals following an intraduodenal infusion of oleic acid is under cholinergic control.

4659 GASTRIN IN THE PERINATAL RAT PANCREAS AND GASTRIC ANTRUM: IMMUNOFLUORESCENCE LOCALIZATION OF PANCREATIC GASTRIN CELLS AND GASTRIN SECRETION IN MONOLAYER CELL CULTURES.

(Eng.) Braaten, J. T.; Greider, M. H.; McGuigan, J. E.; Mintz, D. H. (Ottawa Civic Hosp., Ottawa, Ontario K1Y 4E9, Canada). *Endocrinology* 99(3):684-691; 1976.

The presence and development of immunoreactive gastrin (IRGa) in the fetal and neonatal pancreas and pyloric antrum of Wistar-Lewis rats were studied. IRGa appeared in the pancreas (0.9 ng/mg dry weight pancreas) and antrum (0.9 ng/mg dry weight antrum) at least as early as the 16th day of fetal life. Antral IRGa increased rapidly and continuously in the neonatal period (21 ng/mg in 5-day-old rats; 278

ng/mg in 35-day-old rats), while the pancreatic IRGa concentration increased and was maintained at a relatively constant level (3.25-3.6 ng/mg) from days 5 to 35. Monolayer cell cultures of the neonatal rat pancreas were used to evaluate the role of cyclic AMP-mediated release of gastrin. The addition of 4 mM $N^6,O^{2'}$-dibutyryl cyclic AMP or 4 mM theophylline to the culture medium induced significant release of gastrin (61.2 pg/dish/4 hr), compared to control cultures (15.0 pg/dish/4 hr). The stimulation of adenylate cyclase with cholera toxin (10 ng/ml) also resulted in significant gastrin release from a control level of 5.6 to a level of 72.0 pg/dish/hr. Long-term cultures (18-24 days) released gastrin continuously at a relatively constant rate. The cellular localization of pancreatic gastrin in 7-day-old cultures was performed by immunological techniques, using fluorescein-labeled antibodies to gastrin. The gastrin-containing cells were located at the periphery of most of the endocrine cell clusters. Immunofluorescence techniques for insulin and glucagon also showed that the alpha cells had a similar peripheral distribution, although they were more frequent in number. In contrast, insulin-containing cells were numerous and were present in all areas of the endocrine cell clusters. The studies support the following conclusions: that gastrin is present in the rat pancreas, even as early as late fetal life; that gastrin-producing cells are present and functionally competent in monolayer cell cultures of the neonatal rat pancreas for prolonged periods of time; that gastrin is released from these cells when intracellular levels of cyclic AMP are increased; and that the gastrin-producing cells in pancreatic cell cultures are located at the periphery of the endocrine cell clusters.

SECRETION AND METABOLISM

Hepatobiliary Tract

4663 SUBCELLULAR SITE OF ACETALDEHYDE OXIDATION IN THE RAT LIVER. (Eng.) Corral, R. J. M.; Havre, P; Margolis, J.; Kong, M.; Landau, B. R. (Case Western Reserve Univ. Sch. Medicine, Cleveland, OH 44106). *Biochem. Pharmacol.* 25(1):17-20; 1976.

An approach which utilized the stereospecificity of hydrogen removal in the oxidation of ethanol was used to study the site of formation of NADH during acetaldehyde oxidation in the liver. Slices of liver from white, female Sprague-Dawley rats were incubated with (R)ethanol-1-^3H (1-5 µCi) and (S)ethanol-1-^3H (1-5 µCi) at a concentration of 1 mg/ml and with ethanol-1-^{14}C (0.2-1.5 µCi) in a buffered medium. Uptake of the ethanol was about 50%. For (R)ethanol, the percent uptake of ^3H was similar to the percent uptake of ethanol determined enzymatically. That is, the ratio of ^3H to ^{14}C in the ethanol remaining at the end of incubation was similar to the ratio in the ethanol at the beginning of the incubation. In contrast, the uptake of ^3H from (S)ethanol-1-^3H was about half the uptake of ethanol, i.e., enrichment of ^3H in ethanol occurred, thereby increasing the ^3H:^{14}C ratio in ethanol following incubation. About four times as much of the uptake of ^3H from (R)ethanol-1-^3H as from (S)ethanol-1-^3H was recovered in lactate. About 60% of the ^3H from both isomers was recovered in water. More ^3H was recovered in acetaldehyde with (S) than with (R)ethanol-1-^3H. It is concluded that the (S)-hydrogen of ethanol has much less access to the NADH pool used in pyruvate reduction than does the (R)-hydrogen when the ethanol is metabolized by rat liver slices at concentrations of 1.0-0.5 mg/ml.

4664 THE INHIBITION OF LYSOZYME BY BILE ACIDS. (Eng.) Vantrappen, G.; Ghoos, A. Y.; Peeters, T. (Lab. Gastrointestinal Pathophysiology, A. Z. St. Rafael, 3000 Leuven, Belgium). *Am. J. Dig. Dis.* 21(7):547-552; 1976.

The *in vitro* effect of bile acids on the lysis of

Micrococcus lysodeikticus by lysozyme was studied. Lysozyme activity was assayed by following changes in the turbidity of a suspension. All of the bile acids tested inhibited the lysis of lysodeikticus by the lysozyme. Inhibition was dependent on bile acid concentration and the duration of its incubation with lysozyme, as well as on the properties of the specific bile acid. Conjugation with glycine or taurine increased the inhibition of all bile acids tested. Free chenodeoxycholic acid inhibited the lysozyme (at 0.5 mM) by 11% compared to 58% when conjugated with taurine. In general, sulfation increased the inhibitory effect of free bile acids more than their conjugates, and the di- and trisulfates were more inhibitory than the monohydrates; the inhibition with cholic acid was 11, 40, 49, and 63% with free, mono-, di-, and trisulfates, resp. The inhibition of micelle-forming bile acid was peaked and appeared to be related to the critical micellar concentration. Inhibition for the sulfated bile acids, which do not form micelles, was characterized by a plateau of maximal inhibition. It is suggested that bile acids may have an important influence on intestinal enzyme activity in general.

4665 INFLUENCE OF BILE SALT CHOLERESIS ON PLASMA DISAPPEARANCE AND BILIARY EXCRETION OF SOME ORGANIC ANIONS.

(Eng.) Vonk, R. J.; Meijer, D. K. F.; Mulder, G. J. (Dept. Pharmacology, State Univ. Groningen, Groningen, Netherlands). *Pharm. Weekbl.* 110(51/52):1312-1315; 1975.

The function of biliary micelles in biliary excretion was investigated by determining the phenolphthalein-β-D-glucuronide (PG), dibromosulphthalein (DBSP), and indocyanine green (ICG) excretion in male Wistar rats during taurocholate and dehydrocholate infusion (106 µmol/hr, i.v., in both cases). During the first 15 min after the i.v. injection of PG (200 µmol/kg), PG excretion was stimulated during bile salt infusion; this may have been due to a decrease of the biliary dead space transit time caused by choleresis. PG excretion was decreased during the final 60 min of dehydrocholate infusion and during the final 30 min of taurocholate infusion. During the entire 60-min observation period after the injection of ICG (12.9 µmol/kg), its excretion was markedly enhanced by taurocholate infusion; during dehydrocholate administration this stimulation was much less pronounced. Maximal biliary output of DSBP (75.0 µmol/kg) was stimulated during bile salt administration (75 min), and this was most pronounced when dehydrocholate was infused. The binding of ICG, DBSP, and PG to biliary micelles was studied by sedimenting the micelles using ultracentrifugation (140,000 x *g*, 210 min). The concentration of ICG was plotted versus the length of the centrifuge tube, and by simultaneous infusion of tritium-labeled taurocholate, the biliary micelles were marked. The sedimentation patterns of ^{3}H-taurocholate and ICG, DBSP, and PG were parallel, suggesting that most of the organic anions present in bile are associated with the micelles.

4666 CHOLERETIC EFFECT OF VASOACTIVE INTESTINAL PEPTIDE.

(Eng.) Thulin, L.; Hellgren, M. (Surgical Res. Lab., Karolinska Sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(3):235-237; 1976.

The choleretic effects of an essentially pure form of the vasoactive intestinal peptide (VIP) were studied and compared with previously published results using a crude preparation of VIP (peptide mixture G2). Three dogs that had been fasted overnight and three dogs that had been fed 2 hr before the experiment, all of which had common duct fistulas and were anesthetized, received 10-min infusions of VIP (0.05 and 0.5 µg/kg/min, i.v.). In the fasted dogs, the average total bile output increased from 0.33 g/10 min before the infusion to 0.96 g/10 min after the infusion. The average sodium output increased from 60 to 154 mmol x 10^{-3}/min, and the average amylase output increased from 110 to 203 U x 10^{-3}/10 min. The biliary concentration of sodium was unchanged, while that of amylase decreased. The bile output was essentially unaffected in the animals that were fed. The two doses used gave equal peak responses, but the duration of the effect was doubled or trebled following the highest dose. The results suggest that the choleretic action of VIP is equal to that of the previously reported peptide mixture G2.

4667 EFFECTS OF ACUTE ADMINISTRATION OF TAUROCHOLIC AND TAUROCHENODEOXYCHOLIC ACID ON BILIARY LIPID EXCRETION IN THE RAT.

(Eng.) Eaton, D. L.; Klaassen, C. D. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Proc. Soc. Exp. Biol. Med.* 151(1):198-202; 1976.

The effects of taurochenodeoxycholate (TCD) and taurocholate (TCH) infusions on phospholipid and cholesterol excretion were studied in Sprague-Dawley rats. The bile acid pool was depleted by cannulating the common bile duct. Approximately 15 hr after cannulation, the lowest concentration of bile salt solution (0.78 mg/ml) was infused i.v. at 1.13 ml/hr for 2 hr; the bile salt concentration was increased gradually until a maximal infusion rate (4.3 µmol/min/kg in 25 mg/ml bile salt solution) was reached 28 hr after cannulation. Qualitative thin layer chromatography showed that the intensity of the spot corresponding to TCH decreased during the depletion period, while there was no TCD present until the infusion of TCD. No increase in the TCH fraction of bile acid excretion was evident during TCD infusion; therefore, the increase in total bile acids measured during TCD infusion was due to an increase in TCD excretion. The cholesterol excretion rate fell to 28% of its initial rate 15 hr after cannulation; this rate increased with infusion of each concentration of bile acid, but reached only 66% of the initial excretion rate at the maximal concentration. The rate of phospholipid excretion declined to 35% of its initial rate by the time bile acid infusion was begun; phospholipid excretion increased with each subsequent infusion of bile acid, attaining 125% of the initial rate at the maximal concentration. The bile acid excretion rate dropped to 25% of its initial rate in 8 hr and remained at this rate until bile acid infusion was begun; at the highest infusion rate, bile acid excretion was about 200% of the initial endogenous excretion rate. There were no statistically significant differences between the effects of TCH and TCD on bile acid excretion, phospholipid excretion, cholesterol excretion, or bile flow. Infusions of increasing concentrations of bile acids resulted in corresponding increases in cholesterol and phospholipid excretion, up to a bile acid excretion rate of 2 µmol/min/kg; above this rate, a plateau in cholesterol and phospholipid excretion rates was reached. The data on cholesterol levels during depletion and infusion of bile acids suggest that there are factors, in addition to bile acid excretion, which affect the cholesterol excretion rate.

4668 RAT LIVER MICROSOMES CATALYSE COVALENT BINDING OF ^{14}C-VINYL CHLORIDE TO MACROMOLECULES. (Eng.) Kappus, H.; Bolt, H. M.; Buchter, A.; Bolt, W. (Inst. Toxicology, Univ. Tubingen, D-74 Tubingen, Wilhelmstrasse 56, W. Germany). *Nature* 257(5522):134-135; 1975.

The suggestion that vinyl chloride (VC) may be transformed by the microsomal mixed function oxidase system to a reactive epoxide intermediate was tested further. When 1,2-^{14}C-VC was incubated with rat liver microsomes and an NADPH-regenerating system, the mean amount of VC metabolite binding to 1 mg of microsomal protein was 0.14 ± 0.07 (standard deviation) nmol; less than 0.001 nmol of VC metabolite was bound to microsomes in the absence of the NADPH-regenerating system. VC metabolites were also bound to albumin when it was added to the microsomal incubation. Concanavalin A, containing no cysteine, did not covalently bind VC metabolites, indicating that cysteine participates in the binding reaction. 1-Naphthyl-4(5)-imidazole (10^{-4} M) inhibited covalent binding by 85%, and 1 mM glutathione depressed binding by 30%. The incubation of ^{14}C-VC with a xanthine oxidase model system (10 mg albumin, 0.8 mM hypoxanthine, 8 mU xanthine oxidase, and 0.08 mM EDTA) for 60 min resulted in the binding of 12.6 ± 1.2 pmol of VC metabolites to 10 mg of albumin, when the system was taking up 10 nmol of ^{14}C-VC; no covalent binding to albumin occurred in control incubations containing albumin and 5 mM H_2O_2. This suggests that O_2-radicals convert VC to a metabolite, which then binds covalently to a protein-like albumin. These experiments support the concept of a reactive metabolite of VC involved in carcinogenesis and liver toxicity.

4669 CHANGES IN CHROMATIN DURING THE DEVELOPMENT OF LIVER CELL INJURY INDUCED BY GALACTOSAMINE. (Eng.) Weiss, E.; Gross, V.; Heinrich, P. C. (Biochemisches Institut der Universitat Freiburg im Breisgau, W. Germany). *FEBS Lett.* 64(1):193-196; 1976.

To investigate the mechanism of liver cell damage, the DNA, histones, nonhistone proteins, and RNA were analyzed in chromatin isolated from Wistar rat liver nuclei at 1, 3, and 6 hr after liver cell injury, similar to viral hepatitis, induced by the injection of D-galactosamine·HCl (GalN, 375 mg/kg). Although the total histone and DNA contents remained unchanged after the injection, chromosomal RNA,and nonhistone proteins were significantly decreased at 3 hr (0.077 md/mg DNA and 0.52 mg/mg DNA, resp.) and 6 hr (0.052 md/mg DNA and 0.59 mg/mg DNA, resp.) after GalN treatment, in comparison with controls (0.110 md/mg DNA and 0.80 mg/mg DNA, resp.). Sodium dodecyl sulfate-acrylamide gel electrophoresis demonstrated a quantitative and a qualitative difference in the pattern of nonhistone protein bands at 6 hr. Six hr after the i.p. injection of 1.0 mCi/kg of ^{3}H-leucine, there were marked decreases in ^{3}H-leucine incorporation into nonhistone proteins (specific radioactivity at 6 hr, 4,231) and into histones (2,482), in comparison to total liver proteins (40,330). These data suggest the following sequence of events toward cell death after GalN administration. The decrease in uridine triphosphate (UTP) levels leads to an impaired protein synthesis, either due to the lack of messenger RNA synthesis or to blocked translation. After the critical time of 3 hr, the regulatory important nonhistone proteins with a high turnover are lost, and the nonhistone protein/DNA ratio decreases. Because nonhistone proteins are necessary for gene activation, the important genes on the DNA cannot be transcribed.

4670 THE EFFECT OF D-GALACTOSAMINE AND URIDINE ON THE URACIL NUCLEOTIDE CONTENTS OF ISOLATED RAT HEPATOCYTES. (Eng.) Hofmann, F.; Decker, K. (Biochemisches Institut an der Medizinischen Fakultat der Universitat Freiburg, D-7800 Freiburg, Hermann-Herder Strasse 7, W. Germany). *Biochem. Soc. Trans.* 3(6):1084-1086; 1975.

To determine whether isolated rat hepatocytes are suitable for studies on metabolic pathways involving uracil nucleotides, the response of these cells to D-galactosamine and uridine was compared with that of the intact organ. The functional integrity of the hepatocytes was also monitored. The intracellular ATP, cytosine triphosphate (CTP), guanosine triphosphate (GTP), uridine triphosphate (UTP), and uridine diphosphate-glucose (UDP-glucose) remained in the range of concentration found *in vivo* and in the isolated perfused liver. The leakage of lactate dehydrogenase, glutamate dehydrogenase, glutamate-oxaloacetate transaminase, glutamate-pyruvate transaminase, iditol dehydrogenase, and nucleotide pyrophosphatase to the incubation medium was slightly increased in isolated cells compared with the isolated liver perfused with the same medium. D-galactosamine (4 mM) in the incubation medium decreased the contents of UDP-glucose and UTP to 10% of the normal values (0.24 ± 0.03 and 0.23 ± 0.06 µmol/g, resp.) within 30 min. The GTP and the ATP contents remained nearly constant, whereas intracellular CTP increased. The stimulation of the *de novo* synthesis of uracil nucleotides led to an increase in the total sum of the acid-soluble uracil nucleotides (ΣUMP=1.13-1.41 µmol/g in controls and 1.69-2.29 µmol/g in cells treated with galactosamine). D-glucosamine in the same concentration as D-galactosamine did not elicit a comparable change in the UTP content. Uridine (3 mM) doubled the UDP-glucose content within 200 min, whereas the UTP content increased fivefold. Hepatocytes treated with 4 mM D-galactosamine for 10 min recovered their UTP and UDP-glucose contents within 60 min after the addition of 3 mM uridine to the cell suspension. The metabolic integrity of the hepatocytes, and the close similarity of their response to both D-galactosamine and uridine, make these cells suitable for the studies of UTP- and UDP-sugar-dependent processes.

4671 CHANGES IN NUCLEOTIDE COMPOSITION AND ITS RELATIONSHIP TO MACROMOLECULAR SYNTHESIS IN COUMARIN-INDUCED HEPATOMEGALY.

(Eng.) Nievel, J. G.; (King's Coll. Hosp. Medical Sch., Denmark Hill, London SE5 8RX, U.K.). *Biochem. Soc. Trans.* 3(6):1241-1243; 1975.

The relationship between histochemical changes in glucose 6-phosphatase activity, nucleotide content, and macromolecular synthesis in the liver of coumarin-treated female Wistar rats was investigated. Toxic hepatomegaly induced by the chronic administration of coumarin increased both the concentration and the total amount of pyrimidine nucleotides in the liver. No such effect occurred after the administration of butylated hydroxytoluene or phenobarbitone, used as model inducers for nontoxic liver enlargement. With different doses of inducers, the effect on nucleotide content was apparently related to the toxic potential of the dose given. Glucose 6-phosphatase activity decreased during coumarin-induced liver enlargement, particularly when the enzyme was assayed biochemically. There was also a close correlation between the toxicity of coumarin and other biochemical changes in the liver, such as enhanced capacity of liver ribosomes to incorporate amino acids into protein, stimulation of the metabolism of drugs and other environmental chemicals or steroid hormones, inhibition of glucose 6-phosphatase activity, fat deposition in the liver, and hypertrophy of the endoplasmic reticulum in the cytoplasm. All of these changes can be induced by large doses of corticosteroids.

4672 EFFECT OF SMALL-INTESTINAL BYPASS ON HEPATIC LIPOGENESIS IN RATS.

(Eng.) Kaminski, D. L.; Jellinek, M.; Mueller, E. J.; Menz, L. (St. Louis Univ. Sch. Medicine, St. Louis, MO). *Surg. Forum* 26:395-397; 1975.

To determine whether the hepatic lipid accumulation following intestinal bypass is associated with an increase in hepatic lipogenic enzyme activity, the effect of bypass of 79% of the small intestine was studied in 10 Wistar rats maintained on a normal diet and in 10 obese rats maintained on an 18% fat diet. Ten nonoperated animals maintained on each diet served as controls. Electron microscopy revealed no hepatic lipid accumulation after bypass in the liver specimens of the rats on the normal diet, but steatosis was evident in samples from the obese rats after bypass. There were no alterations in hepatic glycolytic or Kreb's cycle enzymes after bypass in either the animals on the normal diet or those on the high-fat diet, except for increases in phosphofructokinase activity in both groups (normal diet: control=16.5 ± 1.6 mol/min/g, bypass=21.9 ± 1.8 µmol/min/g; high-fat diet: control=6.4 ± 1.6 µmol/min/g, bypass=20.1 ± 4.1 mol/min/g). The activity of the lipogenic enzymes, malic enzyme, glycerol phosphate dehydrogenase, and glucose 6-phosphate dehydrogenase, was significantly increased over controls in rats fed a normal diet and subjected to bypass (7.7 ± 1.5, 378 ± 10, and 4.8 ± 0.7 µmol/min/g, resp. for controls; 14.8 ± 3.0, 421 ± 17, and 8.1 ± 1.1 µmol/min/g, resp., after bypass). Only the activity of glucose 6-phosphate dehydrogenase in the rats on the high-fat diet was increased after bypass (0.3 ± 0.06 µmol/min/g in controls; 2.3 ± 0.05 µmol/min/g after bypass). The results suggest that increased hepatic lipogenesis does not have a significant role in the increased lipid accumulation associated with small intestinal bypass in rats.

4673 CHANGES IN HEPATIC BILE SECRETION FOLLOWING CHOLECYSTECTOMY.

(Eng.) Nahrwold, D. L.; Rose, R. C. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Surgery* 80(2):178-182; 1976.

To determine whether canine hepatic bile secretion is altered by cholecystectomy, the volume and composition of hepatic bile was studied in nine anesthetized dogs before and approximately 18 weeks after operation. Dogs had common duct cannulation, cystic duct ligation, and temporary occlusion of the pylorus. Sodium taurocholate (9 µEq/min, i.v.) was infused during each experiment. Bile volume, electrolyte composition, bile salt output, and ^{14}C-mannitol clearance were determined during this infusion alone and after the addition of secretin (4 U/kg/hr). Cholecystectomy significantly increased bile volume, sodium, and chloride output, and ^{14}C-mannitol clearance, both in response to taurocholate alone and to taurocholate plus secretin. Bile salt output and bicarbonate output were unchanged. The study shows that cholecystectomy significantly alters the volume and composition of hepatic bile. The data indicate that cholecystectomy does not affect ductular function or hepatic secretion of bile salts, but that canalicular function is altered significantly.

4674 EFFECTS ON THE LIVER IN THE RAT OF INGESTION OF *Indigofera spicata*, A LEGUME CONTAINING AN INHIBITOR OF ARGININE METABOLISM.

(Eng.) Christie, G. S.; Wilson, M.; Hegarty, M. P. (Dept. Pathology, Univ. Melbourne, Parkville, Victoria 3052, Australia). *J. Pathol.* 117(4):195-205; 1975.

Liver lesions produced by indospicine were studied in Sprague-Dawley rats maintained on diets containing 96, 48, 24, and 15% of the seeds of the legume *Indigofera spicata*. The two higher levels caused death of most animals in 2-6 weeks. Initial experiments showed that females were more susceptible than males; in all subsequent experiments, females were used, and the experiments were terminated before death occurred. The rats fed the

24% seed diet developed a nodular cirrhosis by 6 weeks and survived up to 18 weeks. The rats fed the 15% seed diet developed cirrhosis at 16 weeks and survived up to 28 weeks. Prior to the onset of cirrhosis, the liver showed a characteristic lesion consisting of hepatomegaly, periportal fatty change, portal cellularity due to proliferation of ovoid and cuboidal duct cells, gross enlargement of the hepatocyte cytoplasm nuclei and nucleoli (in spite of brisk mitotic activity), and focal centrilobular necrosis. The lesion was interpreted as a restricted hepatic response to a growth stimulus, possibly the mobilization of tissue amino acids. Improvement occurred in the rats fed the two lower dosage levels after nodular cirrhosis developed, producing a new parenchyma. Liver sections were available from previous experiments in which a single dose of purified indospicine (1 or 2 g/kg) was administered to female rats; the similarity of the histological changes produced by the purified amino acid to those produced by the ingestion of the Indigofera seed diets indicated that the indospicine content of the seed was the major constituent responsible for its hepatotoxic effect.

LIBRARY U.

4675 IMPROVED LITHOGENICITY OF FASTING HEPATIC BILE BY DIETARY FIBER AND CHOLESTYRAMINE: STUDIES IN MICE AND HUMANS. (Eng.) Hall, R. C.; Klauda, H. C.; Waite, V. M.; Friedman, A.; Feher, J.; Tepperman, J. (State Univ. New York, Upstate Medical Center, Syracuse, NY). *Surg. Forum* 26:435-437; 1975.

The effect of fiber content in the diet and of cholestyramine on the lithogenic index (LI) was studied in mice and humans. After 4-6 weeks on either a synthetic nonfiber diet (with or without 1% cholestyramine) or a chow diet (with or without 1% cholesterol plus 1% cholic acid), half the mice were fed and half were fasted 18 hr prior to the creation of biliary fistulae for 1-2 hr. With the nonfiber diet, fasting failed to improve the LI, but the LI was significantly lowered by adding cholestyramine to the synthetic diet (LI=.31 in fed mice; .23 in fasted mice). This suggests that with fasting, intraluminal bile acid binding decreased, allowing increased reabsorption of bile acids. In five women (3 with gallstones), 14-hr fasting hepatic bile (duodenal juice before gallbladder contraction) and gallbladder bile (after contraction) were analyzed for LI before and 2-3, 6-9, and 8-12 weeks after cholestyramine (16 g/day) administration. Phenobarbital (120 mg/day) was added during the last 2 weeks. LI progressively decreased in all subjects. Bile acid-binding agents such as dietary fiber or cholestyramine should be studied further for their ability to prevent gallstones.

4676 HEPATIC TOXICITY IN THE RHESUS MONKEY TREATED WITH CHENODEOXYCHOLIC ACID FOR 6 MONTHS: BIOCHEMICAL AND ULTRASTRUCTURAL STUDIES. (Eng.) Dyrszka, H.; Salen, G.; Zaki, G.; Chen, T.; Mosbach, E. H. (Veterans Admin. Hosp., East Orange, NJ 07019). *Gastroenterology* 70(1):93-104; 1976.

To study the effect of p.o. chenodeoxycholic acid (10, 40, and 100 mg/kg/day) on hepatic function and morphology, biliary bile acid composition, and the reversibility of changes were investigated in 22 rhesus monkeys. After 6 months of treatment with 40 and 100 mg/kg/day, bile duct proliferation, portal tract inflammation and fibrosis, bile canalicular bleb formation, and hypertrophy of the smooth enodplasmic reticulum were associated with elevated serum levels of SGOT, SGPT, and leucine aminopeptidase. In the bile, the proportion of chenodeoxycholic acid and its bacterial metabolite, lithocholic acid, rose to approximately 85 and 10% of the total bile acids, resp. After chenodeoxycholic acid was withdrawn for 3 months, the hepatic morphological lesions persisted in some animals, although biliary bile acid composition returned to normal. No hepatic abnormalities were seen in the animals treated with 10 mg/kg/day. The findings suggest that long-term treatment of rhesus monkeys with high doses of chenodeoxycholic acid results in severe hepatic histological lesions that can persist after discontinuation of the bile acid.

4677 PRELIMINARY BIOCHEMICAL STUDY OF THE HEPATOTOXICITY OF TETRACHLORO-1,1,1,2-ETHANE IN WISTAR RATS. INFLUENCE OF SEX. (Fre.) Truhaut, R.; Thevenin, M.; Warnet, J.-M.; Claude, J.-R.; Phu Lich, N. SECRETION AND METABOLISM

Intestine

4702 METABOLISM OF ABSORBED ASPARTATE, ASPARAGINE, AND ARGININE BY RAT SMALL INTESTINE IN VIVO. (Eng.) Windmueller, H. G.; Spaeth, A. E. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Arch. Biochem. Biophys.* 175(2):670-676; 1976.

L-[U-^{14}C]aspartate, L-[U-^{14}C]asparagine, and L-[U-^{14}C]arginine were administered luminally into isolated segments of rat jejunum *in situ,* and the radioactive products appearing in venous blood from the segment were identified and quantified. Aspartate (6 mM), administered alone or with 18 other amino acids plus glucose, was absorbed more rapidly than glutamate, but, as with glutamate, less than 1% was recovered intact in intestinal venous blood. Over 50% of aspartate carbon was recovered in CO$_2$, 24% in organic acids (mostly lactate), 12% in other amino acids (alanine, glutamate, proline, ornithine, and citrulline), and 10% in glucose, apparently the first demonstration of gluconeogenesis by the intestine *in vivo.* In contrast to aspartate and glutamine, less than 1% of asparagine was catabolized. About 4% of the absorbed dose was incorporated into the acid-insoluble fraction of the intestine, which was the case with all the amino acids studied. In conventional or germ-free rats, only 60% of arginine was absorbed intact, while 33% was hydrolyzed to ornithine and urea. The urea and 38% of the ornithine were released into the blood; the remaining ornithine was metabolized further by the intestine to citrulline, proline, glutamate, organic acids, and CO$_2$. Catabolism of several amino acids from the lumen, plus glutamine from arterial blood, may provide an important energy source in the small intestine.

4703 LOCALIZATION OF APOLIPOPROTEIN B IN INTESTINAL EPITHELIAL CELLS. (Eng.) Glickman, R. M.; Khorana, J.; Kilgore, A. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Science* 193(4259):1254-1255; 1976.

Indirect immunofluorescence techniques were employed to determine the distribution of apolipoprotein B in rat intestinal epithelial cells. Isolated intestinal cells were prepared either during active lipid absorption or after biliary diversion. Specific immunofluorescence from an antiserum to apolipoprotein B was detected in the apical portion of epithelial cells from bile-diverted animals, demonstrating that a pool of apolipoprotein B is present in the nonabsorptive epithelial cell, and may be a component of intestinal cell membranes. During lipid absorption in normal rats, an early and sustained increase in immunofluorescence was demonstrated, consistent with an increased synthesis of apolipoprotein B during lipid absorption. This study demonstrates that apolipoprotein B is present within intestinal epithelium and provides evidence for the participation of this apoprotein in intestinal lipid transport.

4704 RAT INTESTINAL GLYCOLIPIDS. II. DISTRIBUTION AND BIOSYNTHESIS OF GLYCOLIPIDS AND CERAMIDE IN VILLUS AND CRYPT CELLS. (Eng.) Bouhours, J.-F.; Glickman, R. M. (Hopital Edouard-Herriot, 69374 Lyon Cedex 2, France). *Biochim. Biophys. Acta* 441(1):123-133; 1976.

To study the relation between changes in glycolipid composition and cellular growth in the intestinal epithelium, epithelial cells were isolated from rat intestine and grouped into villus and crypt cell fractions. Glycolipids from each cell fraction were purified and quantitated by fluorimetric determination of glycolipid sphingosine. Significant quantities of ceramide were found in all cell fractions, and accounted for approximately 15% of total glycolipid sphingosine. While villus and crypt cell fractions quantitatively contained differing amounts of sphingosine (4.6 and 1.6 μmol, resp.), all cell fractions contained proportionally similar quantities of sphingosine compared to cellular cholesterol or phospholipid. Individual glycolipids showed

LIBRARY U.

significant differences in distribution between villus and crypt cells. In villus cells, the hematoside content (3.8-17.7 nmol/100 nmol total sphingosine) and the glucosylceramide content were increased in comparison to those in the crypt cells (hematoside content, 3.8-5.7 nmol/100 nmol total sphingosine). The crypt cells showed an increase in trihexosylceramide (2.0-21.6 nmol/100 nmol sphingosine) and ceramide (26.0 nmol/100 nmol sphingosine) content in comparison to villus cells (1.6-13.6 and 15.9 nmol/100 nmol sphingosine, resp.). The rate of uridine diphosphate (UDP) glucose to hydroxy fatty acid ceramide glucosyltransferase was higher in villus cells, while the rate of UDP galactose to lactosylceramide galactosyltransferase was 3-4 times higher in crypt cells. Significant differences in both the distribution and biosynthesis of individual glycolipids occur in crypt and villus cells of rat intestine, which are of possible importance in the process of intestinal cell differentiation.

4705 GLUTATHIONE AND γ-GLUTAMYL CYCLE ENZYMES IN CRYPT AND VILLUS TIP CELLS OF RAT JEJUNAL MUCOSA.

(Eng.) Cornell, J. S.; Meister, A. (Cornell Univ. Medical Coll., New York, NY 10021). *Proc. Natl. Acad. Sci. USA* 73(2):420-422; 1976.

The intracellular concentration of glutathione, the activities of enzymes involved in glutathione metabolism, and the uptake of amino acids were studied in the villus tip cells and the crypt cells of the jejunal mucosa from male Sprague-Dawley rats. A micrometer planing technique was used to separate the epithelial cells, and thymidine kinase was assayed as a marker enzyme to verify the separation of villus tip and crypt cells. This activity increased sharply with increasing distance from the villus tip region. γ-Glutamyl transpeptidase exhibited an opposite activity pattern in the crypt-to-villus gradient, and thus appears to be a villus-specific enzyme. After fasting for 24 hr, the activity of this enzyme per milligram protein increased two- to threefold in both villus tip and crypt cells. No further change occurred in the villus tip cells after fasting for 48 hr or after the 24 hr-fasted animals were fed either protein (8.0 g gelatin, 10 g casamino acids, 400 ml water) or carbohydrate (cane sugar cubes) for 24 hr; the activity in the crypt cells increased moderately. The activities of γ-glutamyl cyclotransferase, γ-glutamyl cysteine synthetase, and glutathione synthetase were lower in the villus tip cells (650, 160, and 400 nmol/hr/mg protein, resp.) than in the crypt cells (1,500, 380, and 730 nmol/hr/mg, resp.). The concentration of glutathione in the crypt cells was 4.3 μmol/g wet tissue, while that in the villus tip cells was only 0.26 μmol/g. Fasting for 24 or 48 hr led to decreased glutathione levels in the villus tip cells (0.02 and 0.11 μmol/g, resp.) and the crypt cells (1.5 and 1.2 μmol/g, resp.). Feeding of carbohydrate after fasting was followed by a further decrease in glutathione (0.02 and 1.0 μmol/g in villus tip and crypt cells, resp.), but feeding protein increased the levels significantly (0.22 and 2.3 μmol/g, resp.). After the cells were incubated with a 30-50 mM radioactive amino acid solution, the uptake values for the villus tip cells were 20, 38, and 25 nmol/10^7 cells for methionine, valine, and glutamine, resp.; for the crypt cells, the respective values were 11, 9, and 16 nmol/10^7 cells. The results support the hypothesis that the transpeptidase, via the γ-glutamyl cycle, functions in amino acid transport; thus, the cycle is more important in relation to the function of the absorptive villus cells than to that of cells of the crypt.

4706 REGULATION OF RAT PROXIMAL INTESTINAL GLYCOLYTIC ENZYME ACTIVITY BY ILEAL PERFUSION WITH GLUCOSE.

(Eng.) Espinoza, J.; Clark, S. B.; Hritz, A.; Rosensweig, N. S. (Departmento de Nutricion y Tecnologia de los Alimentos, Universidad de Chile Sede, Santiago Sur, Santiago, Chile). *Gastroenterology* 71(2):295-298; 1976.

Since the specific activities of fructose-1-phosphate aldolase, fructose-1,6-diphosphate aldolase, and pyruvate kinase are higher in the rat duodenum and jejunum than in the ileum, the failure of dietary sugars to reach the ileum in high concentrations vis-a-vis this gradient was investigated. Wistar rats were fed a carbohydrate-free diet for 3 days, which removed the proximal-distal gradient of enzyme specific activities. Twenty percent glucose was then perfused directly into either the duodenum or the ileum for 3 days. The normal gradient of all three enzymes was restored by both proximal and distal glucose perfusions. Ileal pyruvate kinase was also increased by ileal glucose perfusion, but ileal aldolases were no higher after distal perfusion than after duodenal perfusion. Therefore, the low ileal aldolase levels normally found in fed rats are an intrinsic property of distal intestine and are not due to failure of dietary sugar to reach this portion of the gut. The adaptation of duodenal and jejunal glycolytic enzymes to ileal glucose perfusion suggests a humoral and/or neural mechanism, rather than a direct local luminal effect of the sugar itself.

4707 CIRCADIAN RHYTHMS IN DISACCHARIDASES OF RAT SMALL INTESTINE AND ITS RELATION TO FOOD INTAKE.

(Eng.) Saito, M.; Murakami, E.; Suda, M. (Sch. Medicine Ehime Univ., Shigenobu, Ehime 791-02, Japan). *Biochim. Biophys. Acta* 421(1):177-179; 1976.

To examine the mechanism involved in the circadian rhythm of disaccharidase activity observed in the rat small intestine, the effect of starvation on the maltase and sucrase rhythms was investigated in the jejunal mucosa of male Wistar rats. The activities of maltase and sucrase were low at night and high in the daytime in animals that had been fed from 09.00 hr to 15.00 hr for 2 weeks. Increases in disaccharidase activity were observed at 08.00 hr, 1 hr before the start of feeding. The rhythmic changes in disaccharidase activity continued for at least 2 days after starvation, but completely disappeared after 5 days of starvation. The disaccharidase rhythms may not be a direct consequence of food intake; anticipation of food intake may act as a trigger for initiation of the disaccharidase rhythms.

4708 LACK OF EFFECT OF ALCOHOL ON SMALL INTESTINAL BINDING OF THE VITAMIN B12-INTRINSIC FACTOR COMPLEX.

(Eng.) Findlay, J.; Sellers, E.; Forstner, G. (Hosp. Sick Children, 555 University Ave., Toronto, Ontario, Canada M5G 1X8). *Can. J. Physiol. Pharmacol.* 54(4):469-476; 1976.

To elucidate the mechanism of alcohol-induced vitamin B12 malabsorption, the absorption of ^{57}Co-labeled vitamin B12-intrinsic factor (IF) complex and its binding to mucosal precipitate and brush border fractions of the small intestine was studied in male Wistar rats. The rats were pair-fed with a liquid diet containing ethanol (5 g/100 ml, 35% of calories) or isocalorically substituted sucrose. IF was obtained from rats fasted for 18 hr, and for each trial, the minimum amount of vitamin B12 required to achieve maximum binding to IF was added. Rats fed alcohol exhibited hepatic steatosis, proliferation of the smooth endoplasmic reticulum, and disordered mitochondria after 6 weeks on the diet, and the absorption of vitamin B12 (fed with IF by stomach tube) was reduced significantly (mean ^{57}Co-B12 absorbed in controls=3,180 pg and in alcohol-fed animals=1,950 pg). In contrast, binding of ^{57}Co-labeled vitamin B12-IF complex to mucosal precipitate and brush border fractions was never less than that of fractions from control rats at 4, 8, and 12 weeks on the alcohol diet. Binding to the brush border was significantly greater in alcohol-fed rats at 12 weeks, whether expressed per unit of β-naphthylamidase activity or per mg of protein. Total mucosal sucrase and β-naphthylamidase were unchanged or slightly increased (β-naphthylamidase at 12 weeks) on the alcohol containing diet, indicating that the total brush border membrane was not reduced. Total brush border binding activity was the same in alcohol-fed and control rats at each time period. The results indicate that malabsorption of vitamin B12 in rats fed alcohol cannot be due to decreased binding of the vitamin B12-IF complex by brush border membrane receptors, or secondary to a net decrease in membrane receptors.

4709 EFFECT OF CHOLECYSTOKININ AND 16,16-DIMETHYL PROSTAGLANDIN E_2 ON RNA AND DNA OF GASTRIC AND DUODENAL MUCOSA.

(Eng.) Johnson, L. R.; Guthrie, P. (Univ. Texas Medical Sch., Houston, TX). *Gastroenterology* 70(1):59-65; 1976.

The effects of cholecystokinin-octapeptide (CCK-OP) and 16,16-dimethyl prostaglandin E_2 (16,16-dimethyl PGE_2) on DNA synthesis and on the RNA and DNA content of gastric and duodenal mucosa were examined in rats, and the response was compared to that elicited by gastrin. Twelve fasted male Sprague-Dawley rats were injected with either CCK-OP (20 μg/kg), 16,16-dimethyl PGE_2 (0.2 mg/kg), pentagastrin (250 μg/kg), or saline every 8 hr for 48 hr. The rats were killed, and the incorporation of [^{3}H]thymidine into DNA, as well as the total DNA and RNA content of the mucosa of the oxyntic gland area and the duodenum, were determined. Pentagastrin increased DNA synthesis 60% ($p<0.001$) in gastric mucosa and 90% ($p<0.001$) in duodenal mucosa, compared with rates for saline controls. Neither CCK-OP nor 16,16-dimethyl PGE_2 altered gastric mucosal DNA synthesis. Pentagastrin significantly increased the DNA and RNA content of both the gastric and duodenal mucosa. CCK-OP and 16,16-dimethyl PGE_2 caused a slight but significant increase in duodenal DNA synthesis. CCK-OP did not significantly increase the duodenal DNA content, and 16,16-dimethyl PGE_2 increased the duodenal RNA but not the DNA content. CCK-OP (20 μg/kg) in combination with pentagastrin did not alter the stimulation of gastric DNA synthesis, but significantly decreased the effect of pentagastrin on duodenal DNA. A dose of CCK-OP (370 μg/kg) equimolar to 250 μg/kg of pentagastrin did not stimulate DNA synthesis in either tissue and significantly inhibited stimulation by pentagastrin in both tissues. Low doses of CCK-OP (2.5, 5.0, 10.0, and 20.0 μg/kg) caused statistically significant increases in DNA synthesis and DNA content of the pancreas, but had no effect on either mucosa of the oxyntic gland area or duodenum. 16,16-Dimethyl PGE_2 did not inhibit the stimulation of DNA synthesis or the increases in DNA and RNA content stimulated by pentagastrin. The results suggest that moderate doses of CCK have a weak trophic effect in the duodenum but not in the stomach. Physiological doses of CCK-OP stimulated pancreatic DNA synthesis and increased pancreatic DNA content without affecting these parameters in the oxyntic gland area or duodenum in the same animals. The results also suggest that in the stomach and duodenum, CCK is not as potent a trophic hormone as gastrin and that it inhibits, probably competitively, the trophic effects of gastrin. 16,16-Dimethyl PGE_2 did not stimulate growth and did not interfere with the trophic response to gastrin even though it inhibits acid secretion. However, 16,16-dimethyl PGE_2 did increase the RNA content of the duodenal mucosa, indicating that it may stimulate activity resulting in hypertrophy.

4710 EPITHELIAL CELL LOSS IN REMAINING INTESTINE AFTER SMALL BOWEL RESECTION IN THE RAT.

(Eng.) Weser, E.; Tawil, T. (Univ. Texas Health Science Center at San Antonio, 7703 Floyd Curl Drive, San Antonio, TX 78284). *Gastroenterology* 71(3):412-415; 1976.

The DNA concentration in perfusates of proximal and distal bowel remnants of the resection of 50 cm of small intestine was measured and correlated with the changes of mucosal hyperplasia in male Sprague-Dawley rats. Sham-operated rats served as controls. One and six months after surgery, 50 cm of the remaining proximal or distal remnant were perfused with saline *in vivo*, and the perfusate DNA was assayed. The DNA recovered from the perfusate of the distal remnant was at least twice as much as that from control segments (1 month after surgery: 4.4 ng atoms DNA-P/min versus 2.3 ng in controls; 6 months after surgery: 2.7 versus 1.1 ng, resp.). This was associated with comparable increases in mucosal weight, DNA, and protein concentration per cm of distal remnant. No significant changes were found in perfusate DNA recovered from proximal remnants. This correlated with minimal, if any, changes in mucosal weight, DNA, or protein concentration per cm of these remnants.

LIBRARY U. C.

Increased desquamation of epithelial cells may reflect the hyperplasia of intestinal mucosa after bowel resection. Recovery of intraluminal DNA may prove useful as an index of intestinal adaptation.

4711 INTESTINAL HYPERTROPHY AFTER SMALL INTESTINAL BYPASS IN THE RAT. STUDIES ON METHODS AND REVERSIBILITY OF CHANGES. (Eng.) Fenyo, G.; Hallberg, D. (Dept. Surgery, Karolinska sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(3):261-269; 1976.

Studies were conducted to determine if the hypertrophic changes occurring after jejunoileal bypass in the rat are reversible. A jejunoileostomy was created in female Sprague-Dawley rats, bypassing 85-90% of the small intestine, by means of a self-emptying blind loop. Control animals were subjected to laparotomy and suture-marking of five intestinal segments. At the end of the experiments, intestinal wet and dry weight and villus height were determined in the five different segments of the small intestine taken from both experimental and control animals. After 2 weeks, a significant hypertrophy occurred in the functioning part of the small intestine of the shunt-operated animals, while an atrophy occurred in the blind loop. In a shunt-operated group of animals, the normal anatomy was reestablished after 2 weeks, and the animals were sacrificed 4 weeks later and compared with controls and shunt-operated animals. In the reoperated animals, the hypertrophic changes disappeared and, except for the increased wet weight of one jejunal and one ileal segment (control: 128.8 and 106.9 mg/3 cm in jejunum and ileum, resp.; reoperated: 154.8 and 139.0 mg/3 cm, resp. $p<0.05$), there were no significant differences in comparison to control animals. The villus height did not differ significantly from that of the control animals, except for the second jejunal segment, which had lower villi in the reoperated animals (456 versus 415 μm, $p<0.05$). The experiments demonstrate that the hypertrophic changes of the small intestine of the rat, developing during the 2 weeks after establishment of a jejunoileal bypass, are reversible within 4 weeks.

4712 ACTIVATION OF HEAT-LABILE Escherichia coli ENTEROTOXIN BY TRYPSIN. (Eng.) Rappaport, R. S.; Sagin, J. F.; Pierzchala, W. A.; Bonde, G.; Rubin, B. A.; Tint, H. (Wyeth Labs., P.O. Box 8299, Philadelphia, PA 19101). *J. Infect. Dis.* 133(Suppl.): S41-S54; 1976.

The biological properties of a heat-labile enterotoxin from *Escherichia Coli* were investigated before and after treatment with trypsin. The possibility that proteolytic activation of the enterotoxin might play a role in the pathogenesis of the disease was considered. A vascular permeability factor (PF) was assayed by inoculating the enterotoxin intradermally to the shaved backs of New Zealand albino rabbits. The ability of the enterotoxin to stimulate growth hormone secretion was measured by monolayer cultures of rat pituitary cells. The secretory response was measured by a rabbit intestinal loop assay. Neutralization of the PF by antitoxin and by ganglioside G_{M1} was assayed in rabbit skin. PF was assayed *in vivo* by incubation in ligated rabbit intestinal loops. Trypsin treatment resulted in a 4- to 20-fold increase in PF activity of the enterotoxin. Trypsin treatment of cell filtrates from nontoxinogenic strains had little or no effect on PF. Trypsin-treated culture filtrates required about twice as much cholera antitoxin and about four times more *E. coli* antitoxin for PF neutralization than did control culture filtrates. At least 10 times more ganglioside G_{M1} was required to inactivate trypsin-treated culture filtrates than control filtrates. Trypsin treatment also increased the filtrate's ability to stimulate growth hormone secretion of rat pituitary cells 10-100 times. It was also about 10 times more active in altering the morphology of pituitary cells. The effects on morphology were indistinguishable from those produced by cholera toxin. There was no difference between control and trypsin-treated culture filtrates when compared in the rabbit intestinal loop assay. *In vivo* incubation showed an increasing PF titer from time zero for untreated filtrate, whereas the PF for trypsin-treated filtrate decreased to about 20%, 10 min after inoculation. These findings support the conclusion that, unlike cholera toxin, *in vivo* activation of *E. coli* enterotoxin by host proteolytic enzyme may play a role in the expression of full pathogenicity.

GENERAL

4720 COLONIC BLOOD FLOW IN CAT AND MAN AS ANALYZED BY AN INERT GAS WASHOUT TECHNIQUE. (Eng.) Hulten, L.; Jodal, M.; Lindhagen, J.; Lundgren, O. (Dept. Surgery II, Univ. Goteborg, Goteborg, Sweden). *Gastroenterology* 70(1):36-44; 1976.

An inert gas elimination technique for studying blood flow and flow distribution in the colon was developed on the cat and applied to 55 patients during abdominal surgery. The method involves recording the elimination of intraarterially-injected ^{85}Kr from a colonic segment, whereby the γ- and β-radiation of the tracer is registered simultaneously by a scintillation detector and Geiger-Muller tube, resp. The total blood flow was determined from the recording of γ-radioactivity, and the muscularis blood flow was calculated from the mono-exponential elimination recorded by the Geiger-Muller tube. The relative weights of the muscularis and mucosa-submucosa were determined from dissections or histological sections. With these weights and total and muscularis blood flows, flow in the mucosa-submucosa was calculated. Total colonic blood flow in humans was 18 ml/min and 100 g of colonic tissue. In the muscularis layer, blood flow amounted to 11 ml/min and 100 g of muscularis tissue (n=12), and flow in the mucosa-submucosa was calculated to be 28 ml/min and 100 g of mucosal-submucosal tissue. About 66% of the total blood flow was distributed to the mucosa-submucosa. As the total colonic blood flow was enhanced, the increase in flow was diverted only to the mucosa-submucosa. In cats, the total blood flow, regional blood flow in the muscularis, and regional blood flow in the mucosa-submucosa were 22, 10, and 31 ml/min and 100 g of colonic tissue, resp. About 30% of the blood flow was distributed to the mucosa-submucosa. This demonstrates the great quantitative and qualitative circulatory similarities between the human and feline colons. The greater flow rates recorded in the mucosa is expected, because absorption and secretion, two energy-consuming processes, are located in this layer.

4721 THE EFFECT OF GATROINTESTINAL HORMONES ON THE GASTRIC MICROCIRCULATION. (Eng.) Guth, P. H.; Smith, E. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA). *Gastroenterology* 71(3):435-438; 1976.

The effects of several gastrointestinal hormones on the gastric submucosal arterioles were evaluated in anesthetized cats using an *in vivo* microscopy technique. Alteration in diameter of submucosal arterioles, 40-90 μ in diameter, in response to infusion of different agents into the celiac axis, was measured. Pentagastrin [mean minimal effective dose by close intraarterial infusion (MED-i.a.)=0.02 μg/kg/min; dose for 50% maximum secretory effect by i.v. infusion (D_{50})=0.02 μg/kg/min], the octapeptide of cholecystokinin (OP-CCK; MED-i.a.=0.07 ng/kg/min; D_{50}=2.2 ng/kg/min), natural secretin (MED-i.a.=0.05 U/kg/min; D_{50}=0.02 U/kg/min), and histamine (MED-i.a.=0.04 μg/kg/min; D_{50}=1.5 μg/kg/min) produced arteriolar dilation. Only with histamine and OP-CCK did this occur, with doses that might be considered physiological. Synthetic secretin had no vasodilator activity, suggesting the presence of a contaminating agent in natural secretin. Glucagon had no effect on the submucosal arterioles. In addition, the effect of glucagon on the smaller (10-30 μ) terminal and subterminal submucosal arterioles was studied in the rat by *in vivo* microscopy. Again, no effect was observed with glucagon, but norepinephrine (0.04-0.18 μg/kg topically; 2.4-6.2 μg/kg/min, i.a.) produced vasoconstriction. The latter findings provide strong evidence against a direct effect of glucagon on the gastric microcirculation.

4722 DISTRIBUTION AND ARTERIOVENOUS SHUNTING OF GASTRIC BLOOD FLOW IN THE BABOON: EFFECT OF EPINEPHRINE AND VASOPRESSIN INFUSIONS. (Eng.) Zinner, M. J.; Kerr, J. C.; Reynolds, D. G. (Walter Reed Army Inst. Res., Washington, DC). *Gastroenterology* 71(2):299-302; 1976.

To study the mechanism involved in the control of upper gastrointestinal bleeding by vasoconstricting agents, the effects of 60-min infusions of vasopressin (0.005 U/kg/min) and epinephrine (0.05 μ/kg/min) on gastric hemodyanimcs were determined in seven anesthetized baboons. The total gastric blood flow was measured electromagnetically, and radioactive microspheres (15 ± 5 μ) with three

LIBRARY U. [illegible]

labels were used to determine the regional distribution of gastric blood flow and arteriovenous shunting. The control flow was 55 ± 8 ml/min; 77.4 ± 2.7% of the flow went to the gastric mucosa, and 1.7 ± 0.4% of injected spheres appeared in the liver. Epinephrine infusion resulted in a sustained vasoconstriction to 18 ± 5 ml/min with no autoregulatory escape and no changes in arterial pressure or cardiac output. Vasopressin resulted in a decrease in flow to 14 ± 3 ml/min with no escape. Although cardiac output did not change, there was a significant hypertensive effect during the vasopressin infusion. Neither redistribution of flow nor change in arteriovenous shunting was noted with either epinephrine or vasopressin. The transmucosal electrical potential difference was 62 ± 8 mV, which did not change significantly with either infusion. It appears that the control of bleeding effected by epinephrine and vasopressin is not related to arteriovenous anastomosis, but is purely a function of vasoconstriction.

4723 EFFECT OF FEEDING ON CATABOLISM AND ACTIVITY OF EXOGENOUS GASTRIN IN DOGS.

(Eng.) Woussen-Colle, M. C.; Limbosch, J. M.; Keuppens, F.; de Graef, J. (Dept. Surgery, Free Univ. Brussels, Belgium). *Acta Hepatogastroenterol.* 23(3):216-221; 1976.

The effect of a meal upon the catabolism and activity of exogenous gastrin was tested in four antrectomized and four nonantrectomized dogs with Heidenhain pouches. The meal decreased the serum gastrin level in both the antrectomized and nonantrectomized dogs infused with porcine gastrin (4 μg/kg/hr, i.v.) or human gastrin I (3 μg/kg/hr, i.v.), resp. This decrease amounted to 17 and 15% in the nonantrectomized and antrectomized dogs, resp., 60 min after feeding, and the gastrinemia then returned gradually to control levels. In nonantrectomized dogs, the infusion of a near maximal dose of gastrin increased the acid response to the meal to a level above the maximal histamine-induced (0.08 mg/kg/hr, i.v.) acid output. Exogenous gastrin also increased the acid response to a meal in antrectomized dogs. These data indicate that feeding increases the metabolic clearance rate of exogenous gastrin, which could be related to changes in the intestinal blood flow, and that after feeding, one or more hormones capable of stimulating the acid secretion, but unrelated to gastrin, are probably released. These hormones could be of major importance in the response of denervated pouches to feeding.

4724 PASSIVE ORAL IMMUNIZATION WITH BOVINE IMMUNOGLOBULINS: ENTEROPATHOGENIC Escherichia coli FROM INFANTS AND BOVINE ANTI-E. coli LACTOSERUM ASSAYED IN THE RABBIT ILEAL LOOP MODEL.

(Eng.) Zinkernagel, R. M.; Colombini, A. (Institut de Biochimie, Universite de Lausanne, 21, rue du Bugnon, CH-1011 Lausanne, Switzerland). *Med. Microbiol. Immunol. (Berl.)* 162(1):1-7; 1975.

To evaluate the possible therapeutic or prophylactic effectiveness of immune bovine lactoserum (BLS) antipolyvalent enteropathogenic *Escherichia coli*, its effect on bacterial growth, viability, and bacteria-induced fluid accumulation was examined in rabbit ileal loops. Human enteropathogenic *E. coli* strains 0125:K70 (B15), 0111:K58 (B4), and 055:K59 (B5) (1-3 x 10^9/inoculum) induced the secretion of 4-6 ml of fluid per 10-cm loop. This effect was inhibited effectively by BLS [corresponding to 50 mg immunoglobulin G (IgG)/loop], while the viability of bacteria counts decreased 2- to 25-fold compared with bovine serum albumin. *E. coli* 026:K60 (B6), 0126:K71 (B16), and 0127:K63 (B8) caused moderate secretion (2-3 ml/10-cm loop) that was significantly neutralized by BLS. *E. coli* 086:K61 (B7) and 0128:K67 (B12) did not give positive loops. The fluid secretion was dose-dependent for *E. coli* 0125:K70 (B15) over the range 2.5 x 10^9-8 x 10^9 bacteria/loop. The titration of the effect of BLS on fluid secretion caused by the same strain revealed a dose-dependent decrease. The best inhibition was obtained with 100 mg BLS/loop, the highest dose tested. Anti-*E. coli* antibodies may be a major requirement for protection against *E. coli*-induced intestinal fluid accumulation.

4725 GASTRIC INHIBITORY POLYPEPTIDE (GIP): INTESTINAL DISTRIBUTION AND STIMULATION BY AMINO ACIDS AND MEDIUM-CHAIN TRIGLYCERIDES.

(Eng.) O'Dorisio, T. M.; Cataland, S.; Stevenson, M.; Mazzaferri, E. L.; (Dept. Medicine, Ohio State Univ., Columbus, OH 43210). *Am. J. Dig. Dis.* 21(9):761-765; 1976.

Radioimmunoassayable gastric inhibitory polypeptide (GIP) was measured in extracts of canine antrum, duodenum, jejunum, and ileum, and observations regarding the nutrients that stimulate the release of GIP were extended. The highest GIP concentrations were found in the duodenum (347 ± 53 ng/g) and jejunum (300 ± 68 ng/g). An immunochemical similarity was demonstrable between porcine GIP and canine GIP. Dogs prepared with Mann-Bollman fistulae were given an amino acid (AA) mixture or medium-chain triglycerides (MCT, containing 75.0, 23.0, 1.0, and 1.0% caprylic, octanoic, capric, decanoic, caproic, and lauric acids, resp.) by intraduodenal perfusion. With AA, a peak mean serum concentration of 672 ± 106 pg/ml was reached 15 min after the perfusion began. MCT resulted in a peak mean serum GIP concentration of 504 ± 55 pg/ml 30 min after beginning of the perfusion. When compared to previously reported results, AA and MCT are not as potent as corn oil (long-chain triglyceride) or glucose in stimulating GIP release. It is concluded that immunoassayable GIP concentrations are highest in the canine proximal small intestine, and that AA and MCT are weak stimulants of GIP release in the dog.

4726 CELLULAR KINETICS OF THE INTESTINAL IMMUNE RESPONSE TO CHOLERA TOXOID IN RATS.

(Eng.) Pierce, N. F.; Gowans, J. L. (Baltimore City Hosps., 4940 Eastern Ave., Baltimore, MD 21224). *J. Exp. Med.* 142(6):1550-1563; 1975.

A regimen of immunization with cholera toxoid in PVG/c rats was sought, which would establish a high density of antitoxin-containing cells (ACC) in the lamina propria, and the origin of the ACC was determined. A single i.p. administration of purified toxoid (100 μg) or of crude toxoid (100 antitoxin combining U/ml, p.o.) produced few ACC. The best cellular response was achieved by a single i.p. dose of toxoid in Freund's complete adjuvant, followed by an intraintestinal boost 2 weeks later. ACC appeared in the thoracic duct lymph 2 days after boosting, reaching a peak of about 200,000 ACC/hr at 3-4 days. This was followed by the appearance of large numbers of ACC in the intestine. The i.p. dose of toxoid by itself gave rise to very few ACC in the gut or thoracic duct lymph, but it had clearly primed the gut immune system for a secondary response. Priming was also achieved by the prolonged p.o. intake of toxoid. The importance of the intestinal route for boosting was shown by the failure of i.p. challenge to give an ACC response in the intestine after i.p. priming and by the small response it provoked after p.o. priming. ACC contained predominantly immunoglobulin A in thoracic duct lymphocytes (TDL) and in the lamina propria. Two observations indicated that the major source of the lamina propria ACC was from cells that emerged in the thoracic duct lymph after intraintestinal challenge. The establishment of a thoracic duct fistula immediately before challenge prevented the appearance of ACC in the intestine, and many ACC appeared in the intestine of normal rats after the injection of TDL rich in ACC. Although homing of ACC precursors to the gut was not antigen-dependent, the distribution of ACC in the lamina propria was considerably influenced by the site of the intestinal challenge, the density of ACC being greatest at or distal to the site of injection of toxoid into the lumen of the gut.

LIBRARY U. OF I. [illegible]

4727 A COLON TUMOR MODEL FOR ANTICANCER AGENT EVALUATION. (Eng.) Griswold, D. P.; Corbett, T. H. (2000 Ninth Ave. South, Birmingham, AL 35205). *Cancer* 36(6):2441-2444; 1975.

The development of colon tumors that could be used as models to test the usefulness of drugs in human colon cancers was attempted in mice. The tumors were induced with 1,2-dimethylhydrazine-di-HCl (DMH; 0.2 mg/mouse/week, s.c., for 7 months), N-methyl-N-nitrosourea (MNU; 0.07 mg/mouse per rectum, biweekly for 6 months), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG; 0.04 mg/mouse per rectum, 4 times weekly for 8 months), and N-nitroso-N-methylurethane (NMU; 0.03 mg/mouse per rectum, biweekly for 6 months). Groups of C57BL/6, DBA/2, and C3H mice were tested with all four compounds. Balb/c mice were tested with all agents except MNU, and Swiss mice were used for DMH slides only. Temporary cessation of exposure was based on clinical signs, including body weight. MNU and NMV produced over 50% mortality by the 120th day of exposure. A total of 82 colon tumors were considered suitable for transplantation (from 1,011 mice orginally started). Of the 82 tumors transplanted, 4 were successful. Of these four, there was one type II tumor and two type III tumors produced by DMH. NMU produced a type IV (undifferentiated) colon tumor. The response of these transplants to chemotherapeutic agents used in man was tested. From these preliminary results, the authors suggest that the response of mice to chemotherapeutic agents sufficiently parallels that of human colon tumors to be useful as a predictive model for the selection of new and useful chemotherapeutic agents.

4728 ADVERSE EFFECTS OF JEJUNOILEAL BYBASS ON GROWTH AND DEVELOPMENT. (Eng.) Grosfeld, J. L.; Cooney, D. R.; Csicsko, J. F.; Madura, J. A. (James Whitcomb Riley Hosp. Children, 1100 W. Michigan St., Indianapolis, IN 46202). *Surgery* 80(2):201-207; 1976.

The effect of 90% jejunoileal bypass on growth and development was studied in 20 growing (100 g) male Sprague-Dawley (SD) rats and 15 male, genetically obese, growing (125 g) Zucker fat rats (FR). Twenty unoperated SD rats and 15 FR of similar age and weight served as controls. Animals were evaluated for weight gain or loss, complications, and survival. When the animals were sacrificed after 4 months caliper measurements of long bones, vertebral column, pelvis, and skull were obtained, and brain, liver, spleen, and kidneys were excised and weighed. Liver and gonadal histology were also obtained. The FR had a 20% anastomotic leak rate and a 33% mortality rate. The mortality rate was 5% in the SD rats and zero in controls. There were no anastomotic leaks in SD rats. Bypassed animals showed growth retardation; the mean weight gain of bypassed SD rats was 32% ($p<0.05$) and of FR was 19% of controls ($p<0.05$). Organ weights were similar, except for a smaller brain in bypassed rats [SD=1.05 ± 0.08 g, compared with 1.83 ± 0.08 g in controls ($p<0.05$); FR=1.2 ± 0.12 g, compared with 1.68 ± 0.09 g in controls ($p<0.025$)]. Skeletal development was significantly retarded in bypassed rats [vertebral column=125.9 ± 3.5 mm, compared with 138.3 ± 3.9 mm in controls ($p<0.025$); ileum=39.4 ± 1.1 mm, compared with 46.2 ± 1.5 mm in controls ($p<0.05$); skull circumference=20.2 ± 0.03 mm, compared with 22.5 ± 0.05 mm in controls ($p<0.025$)]. No increase in fatty infiltration of the liver was observed. Spermatogenesis was diminished by 30% ($p<0.05$) in bypassed SD rats. The data document significant morbidity and mortality rates, growth retardation, and diminished spermatogenesis in bypassed adolescent rats. These results imply that jejunoileal bypass may adversely affect intellectual, skeletal, and reproductive development, and the advisability of this procedure in growing subjects is questioned.

4729 A POSSIBLE EXPLANATION FOR POSTOPERATIVE DIARRHEA AFTER COLOSTOMY CLOSURE. (Eng.) Tilson, M. D.; Fellner, B. J.; Wright, H. K. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Am. J. Surg.* 131(1):94-97; 1976.

The hypothesis that the absorptive capacity of the unused distal colon decreases during the period of bypass, explaining the development of postoperative diarrhea after a closure, was tested by comparing the absorptive capacity of the colons of normal female Sprague-Dawley rats with that of the colons of rats with temporary bypass. Net fluxes of water and sodium were determined in normal animals and in animals that had undergone cecoproctostomy; the fluxes were determined by an *in vivo* perfusion method in which perfusate solutions containing either 20 mM glucose or 20 mM mannitol were used. Transit studies were carried out with a perfusate solution containing 5% mannitol; after equilibration to a steady state, a bolus of phenol red was introduced into the perfusate, effluent samples were collected, and phenol red was analyzed by spectrophotometry. The net water flux for the normal colon was 504 μl/hr during perfusion with the mannitol-containing solution; water absorption increased to 120 μl/hr with glucose. In the bypassed colon, the net water flux was 324 μl/hr with mannitol and only 300 μl/hr with glucose. In colons in which the rate of absorption with mannitol perfusate was determined 3-9 days after restoration of function, the rate returned to normal (631 μl/hr), but the rate with glucose perfusate remained low (192 μl/hr). In the normal colon, the rate of net sodium absorption with mannitol perfusate was 57.9 μEq/hr, and the rate was 113.2 μEq/hr with the glucose perfusate. The rate of sodium absorption in the experimental colon was 39.8 μEq/hr with mannitol; with glucose, the experimental colon began to secrete sodium, with a net flux of -47.6 μEq/hr. The dye-dilution curves for normal and experimental animals were superimposable, the calculated mean transit times being 20.78 min for normal colons and 16.85 min for experimental colons. The results suggest that the diminished absorptive capacity of the defunctionalized colon may be an etiologic factor in the pathogenesis of diarrhea after the closure of colostomies in some patients.

4730 SULFATED BILE ACIDS IN GERM-FREE AND CONVENTIONAL MICE. (Eng.) Eyssen, H. J.; Parmentier, G. G.; Mertens, J. A. (Rega Institute Medical Res., Univ. Leuven, Minderbroederstraat 10, B-3000 Leuven, Belgium). *Eur. J. Biochem.* 66(3): 507-514; 1976.

Since the bile acids of the mouse have been less well investigated than those of other laboratory animals, sulfated and nonsulfated bile acids were determined in the intestines and in the feces of 7-month-old germ-free and conventional C3H male mice. The bile acid pools in the gallbladder and small intestine were 21.13 mg/100 g-body weight in germ-free mice and 11.50 mg in conventional mice. The bile acid pools in the cecum and large intestine of germ-free mice were 3.03 mg/100 g, compared to 1.24 mg in conventional mice. Fecal bile acid excretion was 2.93 mg and 4.12 mg/100 g in 24 hr germ-free and conventional mice, resp. The major bile acids from germ-free mice were cholic acid, α-muricholic acid, and β-muricholic acid. Small amounts of chenodeoxycholic and allocholic acid were also present. In addition to these primary bile acids, the secondary bile acids lithocholic, deoxycholic, and ω-muricholic acid, were identified in conventional mice. In both germ-free and conventional animals, significant amounts of chenodeoxycholic and cholic acid were present as the 7-monosulfate esters. The sulfate esters of these bile acids did not exceed 2% of the total bile acids in the small intestine, but accounted for approximately 50% of the bile acids in the cecum and the large intestine. In contrast, the muricholic acids were nearly exclusively found in the non-sulfate fraction. Alkaline hydrolysis without prior solvolysis of the sulfate esters resulted in loss of bile acids and production of artifacts. The bile acids of the mouse cannot be analyzed by methods involving alkaline deconjugation, unless a solvolysis step is included in the procedure.

4731 SIMILAR SENSITIVITIES OF PANCREATIC AND BILIARY SECRETION TO CHOLECYSTOKININ PLUS SECRETIN INFUSION. (Eng.) MacGregor, I. L.; Knill, J. R.; Meyer, J. H. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Am. J. Dig. Dis.* 21(8):641-644; 1976.

The sensitivities of the gallbladder and pancreas to graded increases of cholecystokinin (CCK) with a constant secretin background were investigated in 20 healthy men. The mean basal trypsin concentration during the i.v. infusion of saline in aspirates from the duodenum was 26.95 U/ml. With increasing volume flow stimulated by the addition of secretin (0.25 CU/kg/hr) and the lowest dose of CCK (0.062 IDU/kg/hr) to the infusion, the trypsin and bile salt concentrations decreased. Continued graded increases of CCK (0.125, 0.250, 0.5, and 1.0 IDU/kg/hr) were associated with a simultaneous increase in trypsin and bile salt concentrations and outputs, their dose-response curves being almost superimposable. At the highest dose of CCK, the mean trypsin output was 9.288 KU/30 min. Increasing the CCK dosage from 0.062 U/kg/hr to 0.25 U/kg/hr caused an increase in bile salt output from 65.99 μmol/30 min to 589.79 μmol/30 min ($p<0.001$), which coincided with an increase in trypsin output from 1.533 KU/30 min to 4.501 KU/30 min. Under conditions more closely approaching normal postcibal events, the previously described differing sensitivities of the pancreas and gallbladder apparently do not occur.

DIAGNOSTIC PROCEDURES

4758 USE OF SUBSTRATE-COATED BARIUM SULFATE TABLETS IN THE EVALUATION OF DIGESTIVE ENZYME DEFICIENCY. (Eng.) Kalifa, L. G.; Koehler, R. E.; Margulis, A. R.; Goldberg, H. I.; Stoughton, J. A.; Gibson, R. D. (Sch. Medicine, Univ. California, San Francisco, CA 94143). *Radiology* 120(2):303-306; 1976.

In an attempt to adapt the use of substrate-coated radiopaque tablets to the analysis of digestive enzyme activity, the properties of tablets coated with one of three substrates were studied *in vitro* and *in vivo* in six dogs and in 16 normal humans. Tablets coated with glyceryl tripalmitate, food starch, or an isolated soy protein (promine) remained intact for the full 6-hr observation period when immersed in water, 0.1 N HCl, and simulated gastric juice (2.0 g NaCl, 3.2 g pepsin, 7 ml concentrated HCl, H_2O to make 1,000 ml; pH=1.2). Fragmentation of tablets of each type occurred in 3 hr or less in simulated duodenal juice (650 ml H_2O, 6.18 g KH_2PO_4, 190 ml 0.2 N NaOH, 10 g pancreatin; pH adjusted to 7.5 with 0.2 N NaOH). The tablets all had an enteric coating, but the absence of this coating made no detectable difference in the time required for fragmentation of protein- or starch-coated tablets in the simulated duodenal juice. The addition of dog food to the duodenal juice eliminated tablet fragmentation of all three substrate types. In three dogs that were fasted for 12-18 hr, all tablets remained intact in the small bowel for an average of 2-2.5 hr. Starch- and promine-coated tablets given 30 min after a meal behaved similarly to those given after fasting; the time of the breakdown of tripalmitin-coated tablets was delayed an average of 4.5 hr. The time of onset of fragmentation of the tripalmitin-coated tablets was decreased by the i.v. administration of 3 Ivy U/kg of cholecystokinin (CCK) 5 min before their administration. The diversion of pancreatic secretions from the bowel considerably prolonged the onset of disintegration of the tablet core for all three types of substrate. Catheterization of the pancreatic duct abolished the CCK-induced increase in the rate of breakdown. In the human subjects, all three types of substrate left the stomach by 2 hr, and were fragmented 3 hr later. These results suggest that these tablets may be used in the diagnosis of pancreatic exocrine insufficiency.

4759 USE OF HYPERTONIC-BARIUM MIXTURES IN THE DIAGNOSIS OF THE DUMPING SYNDROME. (Eng.) Seymour, E. Q. (Medical Univ. South Carolina, 80 Barrett St., Charleston, SC 29401). *Am. Surg.* 42(8): 547-553; 1976.

The value of using a hypertonic glucose-barium mixture in the differential diagnosis of the true dumping syndrome and the dumping-like response resulting from an anxiety reaction is described. The patient is given 8-10 ounces of the test meal, which contains 6.25 g glucose/ounce of the meal, averaging about 50-62 g of glucose. In the true dumping syndrome, the bowel wall is edematous and distended with excessive fluid. As the sequence continues, there is considerable flocculation of the barium. Radiographs taken in one patient illustrate this pattern; the extent of the outpouring of fluid was so great that the patient became hypotensive, and i.v. fluids were necessary. Radiographs taken in another patient illustrate that the appearance of the bowel in a negative glucose test for dumping syndrome is similar to that in a standard barium meal test. The author concludes that the hypertonic glucose-barium meal is useful in the diagnosis of the true physiologic dumping syndrome.

4760 COMBINED LACTOSE-d-XYLOSE TOLERANCE TEST IN INFANCY. (Eng.) Chandrasekaran, R.; Kumar, V.; Moorthy, B. (Postgraduate Inst. Medical Education Res., Chandigarh, India). *Digestion* 14 (3):281-284; 1976.

A test in which the lactose tolerance and *D*-xylose tolerance tests are combined was performed in 10 normal infants, and the results were compared to those obtained when each of the tests was performed separately in the same infants. *D*-xylose (1 g/kg, maximum 13 g) and lactose (3.5 g/kg for infants below 1 yr; 2 g/kg in those over 1 yr) were administered alone or in combination by nasogastric tube following a 5-hr fast. Blood samples were collected at 0, 30, 60, 90, and 120 min. The mean peak rise of glucose following the combined test was 47.1 ± 16.4 mg%, and the rise was 46.7 ± 13.0 mg% following the lactose load. Similarly, the mean peak values for *D*-xylose were 45.0 ± 10.4 mg% and 39.9 ± 6.9 mg% for the combined and separate tests, resp. The results suggest that the combined test is as effective as two separate tolerance tests in the evaluation of dissacharide intolerance, and it is much more convenient.

4761 THE EFFECT OF SODIUM TAUROCHOLATE ON BILIAR IODIPAMIDE EXCRETION IN THE DOG. (Eng.) Burgener, F. A.; Fischer, H. W. (Univ. Rochester Sch. Medicine Dentistry, Rochester, NY). *Gastroenterology* 71(3):475-478; 1976.

The effect of sodium taurocholate in stepwise increas ing infusion rates (0.3-9.6 µmol/min/kg) on the biliary excretion rate and concentration of iodipamide, both of which affect the degree of radiographic opacification of the biliary tree during cholangiography, was investigated in six dogs (10 experiments). The bile was completely diverted, and the experiments were performed while the animals were under general anesthesia. Iodipamide was administere i.v. with an initial priming dose of 33 µmol/kg, followed by a constant infusion of 1.3 µmol/min/kg. Although the bile flow continuously increased with an increasing taurocholate dose, the iodipamide excretion rate reached a plateau with a 0.6 µmol/min/kg of taurocholate infusion, which was 20% higher tha with the lowest taurocholate dose. With a taurocholate dose over 2.4 µmol/min/kg, a significant decrease in the iodipamide rate was found, amounting to 22% of its maximum value with the largest taurocholate dose. The bile iodipamide concentration was at its maximum with the lowest taurocholate dose, and it decreased with an increasing taurocholate dose.

LIBRARY U.

Since the bile iodipamide concentration is probably the most important determinant in clinical cholangiography, low bile salt plasma levels should result in the best radiographic visualization of the biliary tree.

4762 A RANDOMIZED TRIAL OF PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY WITH THE CHIBA NEEDLE VERSUS ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY FOR BILE DUCT VISUALIZATION IN JAUNDICE. (Eng.) Elias, E.; Hamlyn, A. N.; Jain, S.; Long, R. G.; Summerfield, J. A.; Dick, R.; Sherlock, S. (Royal Free Hosp., Pond St., London, NW3 2QG, England). *Gastroenterology* 71(3):439-443; 1976.

Sixty consecutive patients who were deeply jaundiced or in whom i.v. cholangiography had failed were randomized to retrograde endoscopic cholangiography or percutaneous transhepatic cholangiography with the skinny Chiba needle technique. The efficacy in demonstrating the bile ducts, the overall diagnostic yields, and the morbidity rates of the two procedures were compared. Twenty-eight patients were assigned to retrograde cholangiography, which succeeded in 17. Percutaneous cholangiography was successful in 16 of the remaining 32 patients. When patients in whom one procedure was unsuccessful were reinvestigated by the other technique, retrograde cholangiograms were obtained in 13 of 16, and percutaneous cholangiograms in 8 of 11. Thus, one or the other technique was successful in 54 of 60 patients. Percutaneous cholangiography was successful in 19 of 29 patients with extrahepatic cholestasis but in only 6 of 31 patients with intrahepatic cholestasis. Endoscopic retrograde cholangiography succeeded in 13 patients with extrahepatic and 19 with intrahepatic cholestasis. Complications occurred only in patients with extrahepatic cholestasis; cholangitis and septicemia occurred in one patient after retrograde cholangiography and in two after the percutaneous technique. An intraperitoneal bile leak occurred in one other patient after percutaneous cholangiography. Percutaneous cholangiography with the narrow needle is a simple, inexpensive, and reliable method for demonstrating the biliary system, and is usually successful when an extrahepatic cause of cholestasis is present. The occurrence of serious complications in patients with extrahepatic cholestasis, despite prophylactic antibiotics, makes early surgery mandatory after both techniques.

4763 TECHNETIUM-99m-PYRIDOXYLIDENEGLUTAMATE, A NEW AGENT FOR GALLBLADDER IMAGING: COMPARISON WITH ^{131}I-ROSE BENGAL. (Eng.) Kubota, H.; Eckelman, W. C.; Poulose, K. P.; Reba, R. C. (Washington Hosp. Center, Washington, DC). *J. Nucl. Med.* 17(1):36-39; 1976.

The distribution of ^{99m}Tc-pyridoxylideneglutamate (^{99m}Tc-PG) was compared with that of ^{131}I-rose bengal to determine whether ^{99m}Tc-PG can be used in human hepatobiliary studies. Approximately 9 μCi in 0.086 ml of the ^{99m}Tc compound and 0.9 μCi in 0.052 ml of the ^{131}I-rose bengal were mixed and injected in New Zealand rabbits; aliquots of various tissues were counted for ^{131}I and ^{99m}Tc by dual nuclide spectral analysis. Two to three milliliters of ^{99m}Tc-PG containing 5-8 mCi of ^{99m}Tc was also injected in eight normal human subjects, followed by sequential imaging with a scintillation camera. In both the rabbit gallbladder and intestine, the activity of the ^{99m}Tc compound per gram was more than 10 times that for blood from 5 min to 2 hr after the injection, indicating that the pharmaceutical is rapidly cleared from the blood by the liver and a fraction is rapidly excreted through the common bile duct into the duodenum. The equilibrium concentration of activity in the gallbladder was reached within 5 min. Within 2 hr, a large amount of the ^{99m}Tc activity (27.47 ± 6.5% of the dose) was excreted in the urine. The ^{131}I activity cleared the blood at a significantly slower rate than the ^{99m}Tc; a liver-to-blood ratio of 10:1 was not reached within the 2-hr analysis time. Ratios greater than 10 for gallbladder-to-blood and intestine-to-blood were reached 30 min after the injection. Urinary excrecion of ^{131}I was less than 3%. The results suggest that a more immediate visualization of the gallbladder is possible with ^{99m}Tc-PG than with ^{131}I-rose bengal because of its early high gallbladder-to-blood and gallbladder-to-liver ratios.

4764 BILIARY TRACT SCANNING WITH ^{99m}Tc-PYRIDOXYLIDENEGLUTAMATE: A NEW GALLBLADDER SCANNING AGENT. (Eng.) Matolo, N. M.; Stadalnik, R. C.; Krohn, K. A.; Jansholt, A.-L.; DeNardo, G. L.; Wolfman, E. F., Jr. (Univ. California Sch. Medicine, Davis, CA 95616). *Surgery* 80(3):317-321; 1976.

Biliary scanning with the new radiopharmaceutical, technetium-99m-pyridoxylideneglutamate (^{99m}Tc-PG), was performed on 15 dogs, 10 normal human volunteers, and 40 patients with hepatobiliary tract disease. The animals were divided into three groups: normal dogs, those with cystic duct ligation, and those with ligation of both the cystic duct and proximal portion of the common hepatic duct. In normal dogs and humans, the agent reached the liver in 5 min and reached the common bile duct (CBD), gallbladder, and duodenum in 10-15 min. Satisfactory images of the biliary tract were obtained with small doses (1-2 μCi) of ^{99m}Tc-PG. The gallbladder was not visualized when the cystic duct or proximal common hepatic duct was occluded. There was no concentration of ^{99m}Tc-PG in the gallbladder when a nonfunctioning gallbladder was demonstrated radiologically in the presence of acute cholecystitis, cystic duct obstruction, or in chronic cholecystitis. In partial CBD obstruction, a distended CBD was visualized, and there was delay in the transit of radioactivity into the duodenum. In complete CBD obstruction, no radioactivity was seen in the biliary and gastrointestinal tracts up to 24 hr after injection, but there was immediate and intense secretion of the radioactive agent into the urogenital system. In severe hepatocellular disease, delayed liver clearance and delayed visualization of the gallbladder were observed. There were no toxic or other untoward effects noted in any patient. Therefore the study can be used for evaluating patients with biliary tract disease. The advantages of biliary scanning include safety, simplicity, and availability, in addition to the fact that it can be performed in jaundiced patients as well as in those allergic to contrast agents used for cholangiography.

4765 ULTRASOUND EXAMINATION OF THE GALLBLADDER: AN ALTERNATIVE TO "DOUBLE-DOSE" ORAL CHOLECYSTOGRAPHY. (Eng.) Bartrum, R. J., Jr.; Crow, H. C.; Foote, S. R. (Dartmouth Univ. Medical Sch., Hanover, NH 03755). *JAMA* 236(10):1147-1148; 1976.

The gallbladders of 50 patients who had a nonvisualized gallbladder following a single 3-g dose of tyropanoate sodium were examined by ultrasound, and the accuracy of this procedure was compared with double dose p.o. cholecystography and with i.v. cholangiography. Gallstones were found at operation in 30 of the 50 patients; the ultrasound examination was positive in 28 of these. Of the remaining patients, the ultrasound examination was equivocal in one and false-negative in the other. In 29 of the 50 patients, the gallbladders remained nonvisualized on the double-dose p.o. cholecystogram. Eleven patients with nonvisualized double-dose cholecystograms also underwent i.v. cholangiography; seven gallbladders were visualized by this technique. The accuracy of ultrasonic cholecystography has been adequately demonstrated, and this procedure should be employed in instances of nonvisualization with single-dose p.o. cholecystography.

4766 DIAGNOSIS OF POSTEROLATERAL CONGENITAL DIAPHRAGMATIC (BOCHDALEK) HERNIA BY LIVER SCINTIGRAM: CASE REPORT. (Eng.) Yeung, W.-C.; Haines, J. E.; Larson, S. M. (Univ. Oregon Health Sciences Center, 3181 S.W. Sam Jackson Park Rd., Portland, OR 97201). *J. Nucl. Med.* 17(2):110-112; 1976.

Hepatic herniation through a right-sided posterolateral congenital diaphragmatic defect (Bochdalek) was diagnosed by ^{99m}Tc-sulfurcolloid scintigraphy in a 4-week-old boy, whose case report is presented. The liver scintigrams showed an oblique band of decreased radioactivity, divided the liver into an inferior anteromedial portion and a superior posterolateral portion. In spite of the markedly abnormal liver scintigram, other diagnostic studies, including pneumoperitoneum abdominal radiography, were negative. The liver scintigram can provide life-saving information in the diagnosis of congenital diaphragmatic hernia.

4767 SIGNIFICANCE OF PERITONEOSCOPIC EXAMINATION, DIRECT CHOLANGIOGRAPHY AND CYTOLOGICAL EXAMINATION OF ASPIRATED BILE IN THE DIAGNOSIS OF BILIARY AND PANCREATIC MALIGNANCIES. (Eng.) Kimura, R.; Wakui, K.; Ishioka, K.; Tadaki, H.; Yamagata, J.; Takeda, T.; Miura, K.; Otsuki, M.; Sugawara, T.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(Suppl.):145-148; 1976.

The value of peritoneoscopic examination, direct cholangiography, and cytological examination of aspirated bile during direct cholangiography was studied in 140 cases of biliary and pancreatic malignant and nonmalignant diseases. The peritoneoscopic diagnosis was correct in 10 of 14 patients with gallbladder cancer, 6 of 20 patients with common bile duct cancer, and 6 of 25 patients with pancreatic cancer; the peritoneoscopic examination usually only revealed obstructive jaundice, and the malignancies that were correctly diagnosed were usually advanced. Forty-three of 71 cases of cholelithiasis were correctly diagnosed with peritoneoscopy. The correct diagnosis was made by direct cholangiography in all of 41 patients with cholelithiasis, in 10 of 11 patients with common bile duct stones, all of 8 patients with combined cholelithiasis and common bile duct stones, in 12 of 14 patients with gallbladder cancer, in 18 of 20 patients with common bile duct cancer, and in 20 of 24 patients with pancreatic cancer. Misinterpretation of the lesion occurred in 1 of 11 patients with common duct stone, and in 2 of 14 patients with gallbladder cancer, and in 2 patients with common duct stones. Cancer cells were detected by cytological examination of aspirated bile in 10 of 12 patients with gallbladder cancer, in 4 of 11 patients with common duct cancer, and in 5 of 11 patients with hepatic bile duct cancer. The detection rate of the cancer cells in the bile was increased when the lesion was closer to that of the aspiration site. It is concluded that the combination of these three methods will lead to correct diagnosis.

4768 THE DIAGNOSTIC VALUE OF BIOPSY OF THE PANCREAS IN PANCREATIC DISEASE. (Ita.) Marrano, D.; Giberti, D. (Istituto di Patologia Speciale Chirurgica e Propedeutica Clinica, Universita degli Studi di Bologna, Bologna, Italy). *Acta Chir. Ital.* 31(3):321-328; 1975.

A pancreatic biopsy should be performed only when absolutely necessary and in certain specific cases. It is of greatest value in tumors of the head of the pancreas, when the tumor is still well defined, when radical surgery is still possible, and when there are no other radiological or clinical means of confirming the diagnosis. Biopsy is of moderate usefulness in chronic relapsing pancreatitis. Results are largely dependent on the surgeon's experience, on the preparation of the specimen, and on the pathologist's interpretation.

GASTROINTESTINAL DISEASES

ESOPHAGUS

4826 LOWER ESOPHAGEAL SPHINCTER PRESSURE IN WOMEN USING SEQUENTIAL ORAL CONTRACEPTIVES. (Eng.) Van Thiel, D. H.; Gavaler, J. S.; Stremple, J. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Gastroenterology* 71(2):232-235; 1976.

Because symptomatic acid reflux and reflux esophagitis occur in some women during pregnancy, the effects of estrogen and progestins on lower esophageal sphincter (LES) pressure were studied by determining the LES pressure, basal gastric pH, and fasting plasma gastrin levels in seven women using sequential oral contraceptives. No difference in basal gastric pH or fasting plasma gastrin was observed during any of the three selected periods studied. LES pressure was the same during menses (20.8 ± 1.7 mm Hg) when the volunteers took no medication and during the phase of the cycle when the volunteers were ingesting ethinylestradiol (18.3 ± 1.7 mm Hg). LES pressure decreased significantly ($p<0.01$) to 9.4 ± 1.2 mm Hg during the phase of the cycle when the volunteer took dimethisterone as well as ethinylestradiol. It is therefore proposed that the progressive rise in plasma progesterone alone or in combination with estrogens that occurs during the course of pregnancy might be responsible for the increased incidence of symptomatic heartburn in pregnant women.

4827 LOWER ESOPHAGEAL SPHINCTER FUNCTION IN CHILDREN WITH AND WITHOUT GASTROESOPHAGEAL REFLUX. (Eng.) Moroz, S. P.; Espinoza, J.; Cumming, W. A.; Diamant, N. E. (Health Sciences Centre, 685 Bannatyne Ave., Winnipeg, Manitoba, Canada). *Gastroenterology* 71(2):236-241; 1976.

Studies were designed to determine: the normal range of lower esophageal sphincter (LES) and upper esophageal sphincter (UES) pressure in infants and children, the LES and UES pressures in infants and children with gastroesophageal reflux (GER), and the responsiveness of the LES to bethanechol chloride in controls and children with GER. LES pressure was assessed in 62 control children and 35 GER children (aged 2 weeks-12 yr). In control subjects, LES pressure was well developed by 2 weeks of age, and at less than 1 yr, the mean LES pressure (43.3 ± 2.4 mm Hg) was significantly greater than that (30.6 ± 2.3 mm Hg) in children older than 1 yr. LES length increased with age. Bethanechol chloride (0.1 mg/kg, s.c.) caused a rise in LES pressure that increased in magnitude as LES resting pressure increased. In the 35 patients with GER, only 16 children had LES pressures below the normal range for their age group. LES length was shorter than control values in children over 6 months of age; hiatus hernia occurred in only five GER patients. Clinical improvement occurred in 15 of 16 infants treated with thickened feedings and upright posturing after meals. Six of these infants had low LES pressure; of the three who were followed up, the LES pressure returned to normal in two, one of whom also had hiatus hernia. Bethanechol chloride caused a change and an absolute rise in LES pressure that were not significantly different from those observed in controls. These results indicate that in infants and children, low LES pressure is not the sole determinant of GER, and that pharmacological stimulation of the LES could be a useful adjunct to the management of GER.

4828 MEDIASTINAL HISTOPLASMOSIS WITH ESOPHAGEAL ABSCESS: TWO CASE REPORTS. (Eng.) Jenkins, D. W.; Fisk, D. E.; Byrd, R. B. (United States Air Force Medical Center, Lackland Air Force Base, TX 78236). *Gastroenterology* 70(1):109-111; 1976.

The case reports of two patients who had ulcerated lesions of the esophagus secondary to *Histoplasma capsulatum*-infected mediastinal nodes are presented. The sudden onset of dysphagia heralded the onset of the disease in both patients. In the first patient, a 13-yr-old boy, a well documented episode of acute histoplasmosis approximately 13 months earlier suggested the diagnosis. At the time of the acute infection, his complement-fixing activity to the Histoplasma organism was 1:128 in the yeast phase and 1:16 in the histoplasmin phase; at the time of the mediastinal node infection, the yeast phase titer was 1:128, and the histoplasmin phase was 1:8. A lesion with a central ulcer was seen protruding into the esophagus posteriorly on an esophagogram, and was confirmed by esophagoscopy. After 2 months of therapy with amphotericin B (total dose, 1,200 mg), the dysphagia resolved, and repeat esophagoscopies were normal. The second patient, a 37-yr-old man, had no previous history of acute histoplasmosis infection, and it was believed that he probably had esophageal obstruction from an impacted foreign body. Fungal serologies showed a reaction of 1:8 to *Histoplasma* in the yeast phase only with negative precipitin reactions. Esophagoscopy revealed a submucosal mass protruding into the esophagus with purulent material oozing from the tip. At surgery, *Histoplasma*-infected mediastinal nodes were discovered. A portion of the mass of abnormal nodes was removed, but that part in contact with the esophagus had to be left intact. The resected mass was filled with caseous material, and areas of necrosis surrounded by epitheliod giant cells were noted. The symptoms resolved after 4 months of treatment with amphotericin B (total dose, 1,500 mg), although the yeast phase complement fixation titer remained elevated at 1:32, 7 months after surgery. Although there was significant elevation in the fungal titers only in the first patient, the authors believe that fungal serologies and precipitin bands should be obtained in all patients with symptoms suggestive of a chronic mediastinal abscess.

4829 THE HISTOLOGIC SPECTRUM OF BARRETT'S ESOPHAGUS. (Eng.) Paull, A.; Trier, J. S.; Dalton, M. D.; Camp, R. C.; Loeb, P.; Goyal, R. K. (Peter Bent Brigham Hosp., 721 Huntington

Ave., Boston, MA 02115). *N. Engl. J. Med.* 295(9): 476-480; 1976.

Biopsy specimens were taken from various levels of the esophagus of 11 patients with Barrett's esophagus (columnar-lined esophagus), and their histology was studied. There were three types of columnar epithelia above the lower esophageal sphincter: atrophic gastric-fundic-type epithelium with parietal and chief cells; junctional-type epithelium with cardiac mucous glands; and distinctive specialized columnar epithelium with a villiform surface, mucous glands, and intestinal-type goblet cells. When present, specialized columnar epithelium was always the most proximal, and gastric fundic epithelium was the most distal epithelium. Junctional epithelium was interposed between gastric fundic and specialized columnar or squamous epithelium. Four patients had unequivocal esophagitis in squamous epithelium, but its presence and severity did not correlate with inflammation or length or type of distal columnar epithelium. The heterogeneity of epithelial patterns in the columnar-lined esophagus explains prior discrepant reports in which only single, though diverse, epithelial patterns were described.

4830 INTRAPHRENIC ESOPHAGEAL LEIOMYOMA ASSOCIATED WITH DIVERTICULA PREOPERATIVELY DIAGNOSED BY ANGIOGRAPHY. (Eng.) Gothlin, J.; Bloch, R.; Sundgren, R. (Univ. Hosp., S-221 85 Lund, Sweden). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 16(6):673-678; 1975.

Two cases of esophageal leiomyoma associated with diverticulum are described. In both patients, a 26-yr-old woman and a 37-yr-old man, a thin layer of the diaphragm covered the proximal portion of the tumor, suggesting that each originated between the two layers of the diaphragm, pushing the parietal layer upward. In the first case, the tumor extended through the hiatus into the abdominal cavity, presumably by secondary growth. The preoperative radiological findings had suggested a hiatal hernia, but selective angiography revealed the diverticula and leiomyoma. The posterior esophageal branch of the left gastric artery passed into the medioventral portion of the diverticulum. The posterior branch of the left phrenic artery followed the cranial surface of the diverticulum, indicating its subphrenic localization. In the second patient, the left lobe of the liver was vascularized by the left gastric artery. Only the posterior branch of the left inferior phrenic artery came from the left gastric artery, while the origin of the anterior branch was not demonstrated. The anterior and posterior esophageal branches passed into the anterior portion of the mass, which was vascularized mainly by the posterior branch from the inferior phrenic artery. It passed into the caudal part of the mass, indicating that it was subphrenically located, but more cranially located than in the first patient. Both patients were fully recovered 2-3 months after left-sided thoracotomy, at which time enucleation of the mass and extirpation of the diverticulum in case 1 were performed. Selective angiography may distinguish between diverticula and hiatal hernia and may disclose a benign tumor.

4858 FASTING SERUM GASTRIN AND BASAL GASTRIC ACID SECRETION.

(Eng.) Petersen, H.; Schrumpf, E.; Myren, J. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 10(7):721-724; 1975.

The relation between serum gastrin (SG) and basal acid secretion (BAO) was studied in 20 healthy young subjects; in 20 patients with various gastrointestinal complaints, but without previous or present ulcer disease; and in 20, 16, and 15 patients with duodenal, pyloric, and gastric ulcer, resp. The gastric secretion of acid was examined 30 min basally and in response to stepwise increasing doses of pentagastrin (0.028, 0.166, 1, and 6 μg/kg/hr). None of the subjects showed basal anacidity. A significant positive correlation was found between the SG concentration and BAO only in the subjects without ulcer; this was mainly due to a close correlation in the 20 healthy volunteers. When BAO and SG were expressed as proportions of calculated maximal acid response (Vmax) and half maximal dose of pentagastrin, resp., the positive correlation between SG and BAO was improved and reached significance also in the individuals with duodenal ulcers. The findings suggest that the serum concentration of gastrin plays a role in the basal gastric secretion.

4859 REDUCTION OF GASTRIC AMMONIA BY AMPICILLIN IN NORMAL AND AZOTEMIC SUBJECTS.

(Eng.) Meyers, S.; Lieber, C. S. (Veterans Admin. Hosp., Bronx, New York, NY 10468). *Gastroenterology* 70(2):244-247; 1976.

The capacity of ampicillin to reduce gastric ammonia production was tested in basal and betazole-stimulated (1.7 mg/kg, i.m.) gastric secretion in 26 subjects. A 7-day course of ampicillin (4 g/day, p.o.) reduced basal gastric ammonia concentration from 5.5 ± 1.4 to 1.8 ± 0.3 mM and post-betazole ammonia from 4.7 ± 0.9 to 1.3 ± 0.3 mM ($p<0.01$) in seven normal control subjects. Similar results were obtained after neomycin (4 g/day, p.o.) or i.m.-administered ampicillin (4 g/day), each given to a separate group of seven control subjects. In five azotemic patients, p.o. ampicillin treatment resulted in a reduction of ammonia concentration from 16.3 ± 4.7 to 3.1 ± 0.7 mM in basal secretion and from 18.3 ± 8.1 to 2.3 ± 0.6 mM in betazole-stimulated gastric juice ($p<0.01$). Antibiotic therapy did not alter the volume of gastric secretion. Gastric acidity appeared lower in azotemic patients and increased significantly after treatment, indicating that the higher ammonia content could account for at least part of the hypoacidity. Because ampicillin is active orally as well as parenterally and can be readily used in renal failure, it may be useful for the treatment of hepatic encephalopathy, especially in the azotemic patient in whom neomycin is toxic.

4860 HUMAN GASTRIN RESPONSE TO SECRETIN AFTER VAGOTOMY.

(Eng.) McLaughlin, M.; Peskin, G. W.; Saik, R. P. (Dept. Surg., Univ. California, San Diego, CA). *Am. J. Surg.* 131(1):69-72; 1976.

To determine if the elevation in serum gastrin levels after secretin infusion in patients with Zollinger-Ellison tumors can be used as a diagnostic marker, the gastrin response to a liquid meal with and without secretin infusion was studied in nine patients undergoing selective or truncal vagotomy with pyloroplasty for duodenal ulcer disease. Fasting basal gastrin levels were significantly increased in eight patients after vagotomy (before vagotomy, 10-115 pg/ml; after, 55-177 pg/ml), but secretin infusion (2 U/kg/hr) did not consistently suppress these levels, either pre- or postoperatively. Infusion of secretin significantly lowered the integrated gastrin response to feeding, both preoperatively (before secretin, 30-1,300 pg/min/ml; after secretin, 13-98 pg/min/ml) and postoperatively (before, 6-603 pg/min/ml; after, 4-470 pg/min/ml), and in eight of nine patients. Vagotomy alone did not significantly alter the integrated gastrin response to feeding. This suggests that secretin infusion remains a helpful diagnostic test, differentiating patients with recurrent ulcer and elevated gastrin levels postvagotomy from patients with occult Zollinger-Ellison syndrome.

4861 EPIDEMIOLOGY OF CANCER OF THE STOMACH WITH SPECIAL REFERENCE TO ITS RECENT DECREASE IN JAPAN.

(Eng.) Hirayama, T. (National Cancer Res. Inst., Tokyo, Japan). *Cancer Res.* 35(11, part 2):3460-3463; 1975.

The epidemiology of stomach cancer and its recent decline in Japan were examined. Data were taken from vital statistics and the results of the National Nutritional Survey. Between 1955 and 1973, the age-specific death rate for stomach cancer declined 25% in 40- to 44-yr-old men and women. In the 45- to 49-yr-old group, the death rates declined 34% for men and 22% for women. Death rates decreased by 35% for men and 30% for women in the 50- to 54-yr-old group. The reductions in the 55-59 and 60- to 64-yr-old groups were 30% in each group for men and 31 and 28%, resp., for women. In the 65- to 69-yr-old group, the death rate declined 19% for men and 31% for women. From 1949 to 1971, milk comsumption in Japan increased 20 times, and egg consumption increased 13.4 times. Oil consumption increased 9.6 times, meat consumption, 8.7 times, and fruit consumption, 3.7 times. No change occurred in the consumption of fish, rice, and vegetables. A retrospective study showed significantly less cancer in people who drink two or more glasses of milk a day. There was less than one-third as much stomach cancer in nonsmoking milk drinkers as smoking milk drinkers. The decline in stomach cancer may be attributed, in part, to increased milk consumption and to an early detection program for cancer.

4862 GASTROESOPHAGEAL REFLUX IN ESOPHAGEAL SCLERODERMA: DIAGNOSIS AND IMPLICATIONS.

(Eng.) Orringer, M. B.; Dabich, L.; Zarafonetis, C. J. D.; Sloan, H. (C-7175 Univ. Hosp., Ann Arbor, MI 48109). *Ann. Thorac. Surg.* 22(2):120-130; 1976.

To define precisely the pathophysiology of esophageal involvement in scleroderma, and to evaluate the place of surgery in the management of gastroesophageal reflux in these patients, the history, barium swallow results, and the results of esophageal function tests were evaluated in 53 patients. The most common esophageal symptoms were heartburn and dysphagia, which were seen in 36 and 27 paients, resp. Abnormal motility was seen radiologically in 43 patients, but gastroesophageal reflux was seen in only 9. Esophageal function tests demonstrated: an abnormal motility in 51 patients and lack of a distal esophageal high-pressure zone in 18, moderate to severe gastroesophageal reflux in 38 patients, and abnormal acid-clearing ability in 50 patients. Eleven patients, including eight with peptic stricture, underwent the combined Collis-Belsey operation. Reflux was abolished in all patients, and dysphagia was abolished in 10. Roentgenograms showed that regression of strictures was complete in five patients and partial in three. Postoperative esophageal function tests in nine patients demonstrated a competent distal esophageal valvular mechanism in seven. Gastroesophageal reflux, not impaired motility, is the major cause of esophageal symptoms in scleroderma. Its effective operative control is not contraindicated by systemic disease.

4863 LYMPHORETICULAR HYPERPLASIA OF THE STOMACH (PSEUDOLYMPHOMA). (Eng.) Martel, W.; Abell, M. R.; Allan, T. N. K. (Univ. Michigan Medical Center, Ann Arbor, MI 48104). *Am. J. Roentgenol.* 127(2):261-265; 1976.

Three cases of chronic peptic ulcer combined with gastric lymphoreticular hyperplasia with long-term follow-up are reported. Epigastric pain and weight loss were common to all three patients. All patients had an ulcerating tumor mass associated with regional or generalized enlargement of the rugae of the stomach. In the first patient, a 17-yr-old boy, surgical exploration revealed an 8 x 5-cm mass on the lesser curvature of the stomach adjacent to multiple enlarged lymph nodes; biopsy and frozen sections indicated an erroneous diagnosis of lymphoma, and a subtotal gastrectomy and gastroenterostomy were performed. In the second patient, a 59-yr-old man, subtotal gastrectomy and gastroenterostomy were performed when an antral mass extending to the serosa and enlarged pyloric lymph nodes were discovered. A firm, raised gastric lesion with a central ulcer involved the mucosa just proximal to the antrum. In the third patient, a 56-yr-old man, a subtotal gastrectomy and gastrojejunostomy were performed when a large antral ulcer was erroneously diagnosed as a malignant gastric lymphoma. The x-rays of this patient showed an irregular ulcerated lesion on the greater curvature of the stomach. The ulcer was within a mass that could only be discerned on spot films with compression, indicating that it represented an ulcer within an intraluminal mass; since this is a salient feature of Carmen's sign, which has been regarded as pathognomonic of an ulcerating carcinoma, it appears that this case is exceptional. The microscopic sections of the stomach in all three patients confirmed the presence of a chronic peptic ulcer whose base was covered by a thin, purulent, and a fibrinous exudate. Hyaline fibrous scar tissue extended deep into the underlying wall, replacing much of the muscularis. Throughout this scar, there were nodules and cords of hyperplastic lymphoreticular cells and scattered plasma cells. The mucosa and submucosa at the margin of the ulcer were infiltrated by proliferating lymphoreticular cells and plasma cells; although the cells of the infiltrate were hyperplastic, neither the pattern of involvement nor the cytologic features were those of malignant lymphoma, and the regional lymph nodes showed no evidence of malignancy. Patients 1 and 3 had other ulcers in the stomach and duodenum, suggesting that multiple ulcers might be more likely to occur in patients with lymphoreticular hyperplasia of the stomach. When the first two patients were reexamined, 13 and 9 yr after operation, resp., both were completely asymptomatic.

4864 IMMEDIATE ENDOSCOPIC DIAGNOSIS OF UPPER GASTROINTESTINAL BLEEDING: ITS ACCURACY AND VALUE IN RELATION TO ASSOCIATED PATHOLOGY. (Eng.) Josen, A. S.; Giuliani, E.; Voorhees, A. B., Jr.; Ferrer, J. M., Jr. (Harlem Hosp. Center, 506 Lenox Ave., Room 11106, New York, NY 10037). *Arch. Surg.* 111(9):980-986; 1976.

The use of endoscopy to identify the source of upper gastrointestinal bleeding was evaluated in 262 patients with active upper gastrointestinal (GI) bleeding who underwent panendoscopy between July 1970 and March 1973. There was 100% accuracy of endoscopic diagnosis as to the anatomical site of bleeding; the etiopathologic definition was 94.7% accurate. The series was divided into two groups, 116 with liver disease and 146 without liver disease. There were 107 patients with varices; 21 without liver disease (small varices) and 86 with liver disease (39 small and 47 large varices). All had associated gastritis. Only 27% of the patients in the liver disease group with varices (cirrhotics) had frank variceal hemorrhage, whereas 57% bled from hemorrhagic gastritis. The diagnostic unit provided early diagnosis, meaningful therapy, organized data gathering, and rough estimates of ultimate prognosis.

4865 NONSURGICAL CONTROL OF MASSIVE ACUTE GASTRIC MUCOSAL HEMORRHAGE WITH ANTACID NEUTRALIZATION OF GASTRIC CONTENT. (Eng.) Simonian, S. J.; Stratoudakis, A.; Lawrence, M.; Mungas, J.; Blackstone, M. O. (Univ. Chicago Pritzker Sch. Medicine, 950 E. Fifty-Ninth St., Chicago, IL 60637). *Surg. Clin. North Am.* 56(1):21-27; 1976.

A simple, safe method of treatment for control of massive acute gastric mucosal hemorrhage is described, and the results of studies comparing 20 patients treated with this method with 15 conventionally-treated patients are presented. The procedure was developed from the observation that gastric HCl played a central role in perpetuating the syndrome. The treatment consists of neutralizing the gastric acid with antacid (60-180 ml of magaldrate/hr, to a pH of 7.0), administered by nasogastric tube. Nineteen of 20 patients treated with this technique stopped bleeding; the remaining patient required surgery. There were no deaths. In contrast, 10 of 15 patients treated with conventional therapy [iced saline lavage and minimal (30 ml/hr) quantities of antacid] stopped bleeding. Four of the remaining patients required surgery, and all five patients eventually died, two of rebleeding following surgery. Of the 19 patients in whom bleeding had been controlled by neutralization, rebleeding occurred in 2; it was controlled in both cases by further neutralization. It appears that this method allows the bleeding to stop by natural clotting and enhances the regenerative healing of the gastric mucosa.

4866 GASTRITIS AND GASTRIC BLOOD FLOW IN HYPERDYNAMIC SEPTIC PIGS. (Eng.) Lucas, C. E.; Ravikant, T.; Walt, A. J. (Wayne State Univ. Sch. Medicine, 540 East Canfield St., Detroit, MI 48201). *Am. J. Surg.* 131(1):73-77; 1976.

Experiments were designed to determine the gastric hemodynamics in a septic model that causes both a hyperdynamic state and acute erosive gastritis. Sepsis was established in 12 pigs by the i.m. shank injection of *Pastuerella multocida* (42 x 10^8 colonies) in triptose phosphate broth; 4 pigs received sterile broth injections (shams), and 8 received sterile saline injections (controls). After 18 hr, cardiac output was measured by both the cardiogreen dilution technique and the radioactive microsphere dilution technique; cardiac output was then compared to total and regional gastric blood flow measured by radioactive microsphere entrapment. Acute erosive gastritis developed in septic pigs in the fundus and body of the stomach; the antrum was spared. Cardiac output was significantly increased in septic pigs (585 ml/min/kg) compared with sham (344 ml/min/kg, $p<0.025$) and control pigs (319 ml/min/kg, $p<0.005$). Total gastric blood flow in the septic pigs (1.22 ml/min/g) and regional blood flow to the fundus (35% of total gastric flow), body (42%), and antrum (23%), were also increased in direct proportion to the increase in cardiac output. These data suggest that acute erosive gastritis is primarily due to an end-organ cellular insult from sepsis, and is not primarily due to a decrease or redistribution in gastric blood flow.

4867 SERUM GASTRIN LEVELS IN CONGENITAL HYPERTROPHIC PYLORIC STENOSIS. (Eng.) Spitz, L.; Zail, S. S. (Children's Hosp., Western Bank, Sheffield S10 2TH, England). *J. Pediatr. Surg.* 11 (1):33-35; 1976.

The hypothesis that, in the presence of the requisite genetic factors, perinatal stress acting via gastrin produces hypertrophic pyloric stenosis was tested by measuring serum gastrin levels in infants with this congenital defect. Blood samples were obtained from 18 infants before surgery (Ramstedt pyloromyotomy) for hypertrophic pyloric stenosis; further samples were taken from 10 3-hr fasted infants on the fourth postoperative day. Control fasting specimens were obtained preoperatively from 10 age- and sex-matched control infants who underwent unrelated minor surgery. The mean serum gastrin level of the index patients preoperatively was 170.50 pg/ml, compared with a mean in control cases of 99.60 pg/ml. The serum gastrin levels in all cases increased postoperatively to a mean of 204.40 pg/ml. All differences were significant ($p=0.0015$).
It remains uncertain as to whether the hypergastrinemia in infants with congenital hypertrophic pyloric stenosis is a cause or effect of the pyloric obstruction. The evidence suggests that gastrin may play a small but significant part in the pathogenesis of the condition, but the authors believe that the major cause of the high serum gastrin levels is mechanical antral distension secondary to the obstruction.

4868 CHRONIC GASTRIC ULCER IN THE RAT PRODUCED BY WOUNDING AT THE FUNDO-ANTRAL JUNCTION. (Eng.) Wong, J.; Loewenthal, J. (Dept. Surgery, Univ. Sydney, Sydney, New South Wales, Australia). *Gastroenterology* 71(3):416-420; 1976.

The rates of wound healing at different sites in the stomach, especially at the fundo-antral junction, were evaluated in albino rats. Standardized 8-mm mucosal wounds were made in the stomach at the rumeno-fundic junction, fundus, fundo-antral junction, and antrum, and examined at intervals up to 8 months. All wounds at the rumeno-fundic junction and fundus were healed within 4 weeks, and those at the antrum were healed within 12 weeks. The majority of wounds at the fundo-antral junction remained chronic, and at 8 months, 41 of 50 rats still had ulcers 2 mm or greater in diameter. These findings suggest that the fundo-antral junction susceptible to the development of chronic ulcers. This is a simple and reliable method of producing chronic gastric ulcers and does not alter the continuity or disturb the function of the gastrointestinal tract.

Peptic Ulcers

4907 INHIBITORY EFFECT OF A CAERULEIN-LIKE PEPTIDE ON HUMAN GASTRIC SECRETION.

(Eng.) Agosti, A.; Missale, G.; Bertaccini, G. (Dept. Gastroenterology, Univ. Parma, Parma, Italy). *Eur. J. Pharmacol.* 38(1):193-195; 1976.

The effect of a cerulein-like peptide on gastric secretion was studied in 10 patients with duodenal ulcer. The synthetic heptapeptide corresponds to the C-terminal heptapeptide of cerulein, but is characterized by a norleucine residue replacing the methionine residue of cerulein. When the heptapeptide was infused i.v. (2 μg/kg/hr) in five patients, pentagastrin (4 μg/kg/hr)-stimulated gastric secretion was inhibited by 70-80%. The infusion of the heptapeptide alone caused a slight increase in gastric secretion in the remaining five patients. The compound caused no side effects and exhibited a prolonged effect that was evident even after discontinuing the infusion. This peptide is probably the best cerulein analogue acting as a competitive inhibitor of pentagastrin-induced secretion.

4908 THE EFFECT OF INTRAVENOUS THEOPHYLLINE ETHYLENEDIAMINE ON SERUM GASTRIN CONCENTRATION IN CONTROL SUBJECTS AND PATIENTS WITH DUODENAL ULCERS AND ZOLLINGER-ELLISON SYNDROME.

(Eng.) Feurle, G.; Arnold, R.; Helmstadter, V.; Creutzfeldt, W. (Medizinische Poliklinik, Universitat Heidelberg, Hospitalstrasse 3, D-69 Heidelberg, W. Germany). *Digestion* 14(3):227-231; 1976.

The value of the i.v. infusion of aminophylline in the differential diagnosis of the Zollinger-Ellison syndrome was tested. Serum gastrin concentrations were measured after theophylline ethylenediamine (5-6 mg/kg for 5 min) was infused in 10 patients with duodenal ulcer, 9 patients with the Zollinger-Ellison syndrome, 7 normal control subjects, and 3 patients with pernicious anemia. All but two patients with the Zollinger-Ellison syndrome had been totally gastrectomized. A significant increase in serum gastrin (i.e., >20%) occurred in five controls, six patients with duodenal ulcer, eight patients with the Zollinger-Ellison syndrome, and all three patients with pernicious anemia. It is concluded that an aminophylline test would not be useful in the differential diagnosis of the Zollinger-Ellison syndrome.

4909 CONGENITAL CAUSES OF DUODENAL ULCERS IN ADULTS.

(Eng.) Naylor, R. G.; Juler, G. L. (Univ. California Irvine, Sch. Medicine, Irvine, CA). *Arch. Surg.* 111(6):658-662; 1976.

Seven cases of duodenal ulcers caused by congenital anomalies are discussed. Over a 13-yr period in one hospital, there were two cases of congenital duodenal web, two cases of hypertrophic pyloric stenosis, two cases of annular pancreas, and one case of a preduodenal portal vein; a representative case study of each anomaly is presented. The first patient, a 50-yr-old man, had a sliding esophageal hiatal hernia without reflux, gastritis, gastric ulcer, and pyloroduodenal fistula. At surgery, an eccentric fenestrated duodenal membrane 2 cm distal to the pylorus, with a proximal posterior wall ulcer adjacent to the web, was found. Excision of the web, a truncal vagotomy, and a drainage procedure were necessary in both patients with webs. The second patient, a 51-yr-old man, had a perforated anterior pyloric channel ulcer with marked circumferential pyloric hypertrophy; a biopsy specimen revealed hypertrophic pyloric stenosis. Both patients with this anomaly had increased gastric acid secretion consistent with the previously reported observation that gastric outlet obstruction increases the hormonal phase of acid secretion. Treatment consisted of a Heineke-Mikulicz pyloroplasty and truncal vagotomy. In the third patient, a 45-yr-old man, an annular pancreas was found with a proximal 1-cm duodenal ulcer on the posterior wall of the bulb. Posterior gastrojejunostomy and truncal vagotomy were performed. The presence of a scarred duodenal bulb obscured the preoperative radiological diagnosis in both patients with this anomaly. The last patient, a 28-yr-old man, had endoscopic findings indicative of the Zollinger-Ellison syndrome (duodenal ulcer, gastritis, and duodenitis). At surgery, a preduodenal portal vein, associated malrotation of the gut, and a postbulbar duodenal ulcer were found. A gastroduodenostomy was performed anterior to the portal vein and a truncal vagotomy was performed. The authors conclude that in all cases of congenital obstruction and peptic ulcer disease, treatment should be directed toward relief of the obstruction and the reduction of basal acid secretion.

4910 GASTRIC ACID HYPERSECRETION IN CHILDREN WITH DUODENAL ULCER.

(Eng.) Christie, D. L.; Ament, M. E. (Children's Orthopedic Hosp. Medical Center, Seattle, WA). *Gastroenterology* 71(2):242-244; 1976.

Rates of gastric hydrochloric acid secretion were compared in 10 children with active duodenal ulcer and 14 children without ulcer. Duodenal ulcer was diagnosed by gastroduodenoscopy or by evidence of an ulcer crater on upper gastrointestinal radiographs. Duodenal ulcer disease was excluded in the comparison group by similar criteria. The mean basal acid output in the children with duodenal ulcer (3.2 mEq/hr or 0.064 mEq/kg/hr) was higher than in controls (1.3 mEq/hr or 0.248 mEq/kg/hr), but the difference was not statistically significant. Maximal acid output was significantly higher in the children with duodenal ulcer (21.6 mEq/hr or 0.486 mEq/kg/hr) than in the control group (10.4 mEq/hr, $p<0.025$ or 0.248 mEq/kg/hr, $p<0.005$). Peak acid output was also higher in the patients with duodenal ulcer (23.6 mEq/hr or 0.507 mEq/kg/hr) than in the control group (13.5 mEq/hr, $p<0.05$ or 0.332 mEq/kg/hr, $p<0.025$). These results demonstrate that, on the average, hypersecretion of gastric acid does occur in children with duodenal ulcer disease.

4945 RAPID LONG TUBE INTUBATION OF THE JEJUNUM BY A NEW ENDOSCOPIC DEVICE.

(Eng.) Johnson, F. W.; Goodale, R. L.; Leonard, A. S.; Varco, R. L. (Univ. Minnesota Health Sciences Center, Minneapolis, MN 55455). *Am. J. Surg.* 131(1):91-93; 1976.

The development of a special tube attachment adapted to a fiberoptic duodenoscope (Olympus Model GIF-K) has facilitated asceptic preoperative intubation of the small intestine for decompression of the obstructed loops, a procedure which had formerly been complicated by the difficulty in passing the tube through the pylorus. Under direct endoscopic vision, the tube can be carried into the second and third portion of the duodenum, released from the scope, and then further prodded into the jejunum. The procedure takes less than 15 min. Rapid intubation was easily carried out in five patients whose case reports are presented. Three patients had mechanical bowel obstruction. Rapid and effective decompression allowed adequate time for stabilization of concomitant problems, such as marked cardiopulmonary dysfunction secondary to a near fatal pulmonary embolus, severe peritonitis post appendectomy, and acidosis and dehydration. Surgical correction of the obstructing lesions was safely deferred for up to 1 week until the concomitant problems improved. The fourth patient, who was a renal transplant recipient, had chronic gastric ileus secondary to duodenal ulcer. Rapid passage of the long tube into the jejunum allowed restoration of nutrition and avoidance of gastrostomy. The fifth patient, with an ileus secondary to an infected abdominal aortic graft, underwent successful decompression, but died of sepsis. He was the only mortality. Jejunal intubation using this technique is rapid, relatively easy, and should encourage the wider acceptance of asceptic long tube intestinal decompression.

4946 MORPHOGENESIS OF DUODENAL ADENOCARCINOMAS INDUCED BY N-ETHYL-N'-NITRO-N-NITROSOGUANIDINE IN MICE AND RATS.

(Eng.) Matsuyama, M.; Nakamura, T.; Suzuki, H.; Nagayo, T. (Aichi Cancer Center Res. Inst., Kanokoden 81-1159, Chikusa-ku, Nagoya 464, Japan). *Gann Monogr. Cancer Res.* 17: 269-281; 1975.

The early morphological changes following the induction of duodenal adenocarcinomas by N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG) were studied in CBA/H-T6 mice and Wistar rats. The results of previously reported studies on the induction of duodenal adenocarcinomas by ENNG and N-methyl-N'-nitro-N-nitrosoguanidine and on the ultrastructure of the early lesions are reviewed. In the present study, one group of mice were given ENNG (500 mg/l) in the drinking water for 4, 8, or 12 weeks. The mice were killed after 8 more weeks of treatment with plain water. Two types of initial morphological changes were seen to be involved in the development of lesions after 12 weeks of treatment: enlargement of a single villus and fusion of several villi. In the first type, atypical glands occupied the whole lamina propria as blind cysts without transitional communication with the covering epithelium; in the second type, several atypical glands were situated in the lamina propria of the fused villi. The intravillous lesions proliferated upward and laterally, and eroded the surface of the villi (crater-form lesions). The latter increased in size and developed into macroscopic lesions. This sequence of morphological events was confirmed by counting the number of each of the three lesions at various time intervals; the number of the intravillous lesions decreased, and the number of crater-form and macroscopic lesions increased as the treatment progressed. Mice given 50 mg/l ENNG for 48 weeks had about half the number of intravillous and crater-form lesions, but twice the number of macroscopic lesions as the mice given 500 mg/l for 4 weeks. Similar morphological changes were observed in Wistar rats given 500 mg/l of ENNG for 20 weeks. No duodenal erosions or ulcers occurred in mice given 500 mg/l of ENNG for 1, 3, 7, or 28 days. The systematic examination of serial sections of the intravillous lesions revealed that the surface cells of the villi and crypts were normal. Transitions from normal to abnormal were not observed, suggesting that neoplastic changes occur in the middle proliferating zones of the crypts, penetrating directly into the lamina propria of the villi. The results suggest that the ENNG carcinogenesis in the duodenum occurs in a single step.

4947 RESURGENCE OF TWO FETAL ALDOLASES IN RAT DUODENAL ADENOCARCINOMAS.

(Eng.) Banroques, J.; Martin, M. S.; Martin, F.; Hatzfeld, A.; Schapira, F. (Institut de Pathologie Moleculaire, 24, rue du faubourg Saint-Jacques, 75014 Paris, France). *Biomedicine* 23(9):382-386; 1975.

Kinetic, electrophoretic, and immunological studies were carried out in well-differentiated rat adenocarcinomas to determine the activities of fetal aldolases. Small intestinal carcinomas were induced in Lewis rats by N-methyl-N'-nitro-N-nitrosoguanidine. Original tumors were transferred into syngeneic animals by i.m. injection of a tumor cell suspension. The resulting passages of solid tumors were grown as s.c. grafts into the anterior wall of the thorax. The aldolase content of these tissues was compared with that in normal and fetal (day 15-21 of gestation) intestinal tissues from Wistar rats. The mean aldolase activity ratio of fructose-1-6-diphosphate to fructose-1-phosphate (FDP/FIP) in normal adult rats was 1.33, corresponding to the presence of aldolase B with a small amount of aldolase A. The aldolase activity ratio of normal Lewis rats was identical (1.3). In contrast, the ratio in the fetal intestine was 19.0 at the 15th gestational day, which progressively decreased, reaching 1.4 at birth. Electrophoretic studies confirmed that the aldolase of adult intestine was almost exclusively aldolase B (a strong cathodic band of B4 with an hybrid A.B). In both 16-day fetal intestine and in adenocarcinoma, the electrophoretic pattern showed several anodic bands, demonstrating that two types of aldolase, A and C, hybridize together in these tissues. Using the Ouchterlony method, no precipitation line was found between antiserum anti-aldolase B and an extract of adenocarcinoma. In contrast, a precipitation line was found between antiserum anti-aldolase C and a tumor extract, confirming the abnormal presence of aldolase C in these adenocarcinomas. This study demonstrates the resurgence of both fetal aldolases A and C in adenocarcinomas of mucosal origin.

4948 SMALL BOWEL MUCOSAL DYSFUNCTION IN PATIENTS WITH CYSTIC FIBROSIS. (Eng.) Morin, C. L.; Roy, C. C.; Lasalle, R.; Bonin, A. (Sainte Justine Hosp., 3175 St. Catherine Rd., Montreal H3T 1C5, P. Q., Canada). *J. Pediatr.* 88(2):213-216; 1976.

Disaccharidase activity, L-ananyl-L-phenylalanine (L-ALA-L-Phe) hydrolase activity, and intestinal uptake of three ^{14}C-labeled amino acids were measured in jejunal biopsies from 37 children with cystic fibrosis (CF), 16 children with untreated gluten-induced enteropathy, and 18 control subjects. Lactase, sucrase, and maltase activities, and L-ALA-L-Phe hydrolase activity, were significantly reduced ($p<0.01$) in CF patients (2.4, 10.3, and 30.5 U/g mucosa and 29.1 U/mg mucosal protein, resp.) compared to control subjects (4.0, 10.1, and 34.1 U/g and 29.1 U/mg, resp.). Definite hypolactasia was also observed in 23% of the children with CF. Lysine uptake was normal in CF patients, whereas uptake of 0.01 mM phenylalanine and 0.5 mM cycloleucine was reduced (distribution ratio, 25.5 and 6.6 mM, resp.) compared to controls (38.7 and 9.8 mM, resp.). Disaccharidase activity, L-ALA-L-Phe hydrolase activity, and amino acid uptake were all significantly reduced in patients with gluten-induced enteropathy. This study suggests the presence of an intestinal component to the malabsorption of patients with CF.

4949 TREATMENT OF POSTOPERATIVE REACTIVE HYPOGLYCEMIA BY A REVERSED INTESTINAL SEGMENT. (Eng.) Fink, W. J.; Hucke, S. T.; Gray, T. W.; Thompson, B. W.; Read, R. C. (Veterans Admin. Hosp., Fayetteville, AR 72701). *Am. J. Surg.* 131(1):19-22; 1976.

The value of using reversed (antiperistaltic) intestinal segments as a treatment for postoperative reactive hypoglycemia was studied in 11 men who developed the dumping syndrome and late phase with disabling reactive hypoglycemia (range, 12-50 mg/100 ml). Five patients underwent 50-75% Billroth II gastrectomy, one of whom also underwent vagotomy. Three patients had 50-75% Billroth I gastrectomy, one of whom also had a vagotomy. Three patients underwent vagotomy and pyloroplasty. The patients were treated an average of 7 yr after gastric surgery with a 10-cm reversed jejunal segment. The reversal was placed at the gastric outlet in six patients and just below the ligament of Treitz in five. The former technique produced a somewhat better correction of hypoglycemia than did the latter. A good result was obtained in all patients, and none has had recurrence of seizures or fainting. Whereas the average minimal blood sugar before reversal was 34 mg/100 ml, after reversal it was increased to 64 mg/100 ml. The most severe hypoglycemia was noted in a patient after vagotomy and pyloroplasty. The authors recommend that all patients with dumping syndrome undergo glucose tolerance tests and plasma insulin determinations to ascertain whether they have reactive hypoglycemia. A reversed jejunal segment can control refractory reactive hypoglycemia resulting from previous gastric surgery.

4950 THE EXCLUDED SMALL-BOWEL SEGMENT: A SOURCE OF COMPLICATIONS AFTER SMALL-BOWEL BYPASS. (Eng.) Harmon, J. W.; Aliapoulos, M.; Braasch, J. W. (Walter Reed Army Medical Center, Washington, DC). *Arch. Surg.* 111(9):953-954; 1976.

Two cases of obstruction of the bypassed small intestine after jejunoileal shunt for obesity are presented. The first patient, a 39-yr-old woman, experienced abdominal pain 17 months after the bypass operation. At laparotomy, 500 ml of free abdominal fluid were aspirated, and a loop of excluded small intestine that was obstructed and viable was found to have herniated through a mesenteric defect. The second patient, a 27-yr-old man, developed abdominal pain 8 months after bypass. At laparotomy, many loops of tensely distended small intestine were seen. Aspiration yielded 3,000 ml of fluid. A 360-degree volvulus of a portion of the excluded loop around the anastomosis of the small intestine to the sigmoid was discovered. The volvulized segment was resected, the sigmoid colon was closed, and the distal end of the remaining excluded loop was brought out as a mucocutaneous fistula. Several mesenteric defects were closed. Two months later, the fistula was disconnected, and the bypassed bowel was anastomosed to the cecum. Difficulty in evaluating an acute abdomen after a patient has undergone bypass stems from residual obesity and from the fact that the bypassed intestine is removed from the fecal stream and may not be visualized on the roentgenogram, despite obstruction (as in the first patient). The upright abdominal roentgenogram of the second patient showed air fluid levels, presumably formed by enteric bacteria. The prevention of bypassed bowel obstruction involves the closure of all mesenteric defects at the original operation.

4951 BYPASS ENTERITIS: A NEW COMPLICATION OF JEJUNOILEAL BYPASS FOR OBESITY. (Eng.) Passaro, E., Jr.; Drenick, E.; Wilson, S. E. (Veterans Admin. Hosp. Center, Los Angeles, CA 90073). *Am. J. Surg.* 131(2):169-174; 1976.

Case reports of four patients who underwent jejuno-ileal bypass for obesity and who subsequently developed bypass enteritis are presented. The operation in each instance was end-to-end anastomosis of 12 inches of proximal jejunum to 6 inches of distal ileum. The bypassed segment of the small bowel was drained by ileosigmoidostomy. Bypass enteritis consisted of a sudden onset of abdominal distension and tenderness, increased frequency of diarrhea, and fever of up to 104 F. Abdominal x-rays showed air-filled, dilated small bowel loops without fluid levels. In two patients, pneumatosis cystoides intestinalis was noted, and in one patient, the presence of free intra-abdominal air was noted. Initially, the patients were thought to have intra-abdominal infection. Two of these patients underwent operation for suspected peritonitis from abscess or obstruction, neither of which was found. The bypassed bowel contained many subserosal gas-filled blebs. The other two patients were treated with antibiotics and showed prompt improvement. It is concluded that bypass enteritis must be considered in the postoperative period in patients undergoing surgery for morbid obesity. It responds to antibiotics and appropriate electrolyte therapy. The presumed factor is overgrowth of enteric bacteria in the distal portion of the bypassed bowel. Accurate diagnosis will obviate the need for surgical exploration to exclude peritonitis.

4952 FATAL EOSINOPHILIC ENTERITIS. (Eng.) Tytgat, G. N.; Grijm, R.; Dekker, W.; den Hartog, N. A. (Wilhelmina Gasthuis, Div. Gastroenterology, le Helmersstraat 104, Amsterdam, Netherlands). *Gastroenterology* 71(3):479-483; 1976.

The case of a 66-yr-old man with fatal eosinophilic enteritis of the jejunum is reported. The patient presented with anorexia, vomiting, mild constipation, and a firm periumbilical mass. X-ray examination of the small intestine using the enteroclysis technique revealed two areas of marked irregularity and narrowing. At laparotomy, a huge, firm inflammatory mass involving the proximal 60 cm of jejunum was found. The bowel loops were inflamed, firmly adhering to each other, and covered by a thick layer of fibrinous exudate. The diagnosis was made after pathological examination revealed that the whole thickness of the bowel wall was infiltrated by a dense infiltrate consisting of granulation tissue, lymphocytes, plasmocytes, and numerous mature-looking eosinophils. The eosinophilic infiltration eroded the overlying mucosa, producing acute superficial ulceration. Serological testing for toxoplasmosis, anisakiasis, toxocariasis, ascariasis, trichinosis, and other parasitic diseases was negative. The patient developed bacterial overgrowth in the proximal small bowel. Treatment with prednisone (15 or 30 mg/day), parenteral nutrition, elemental diet, and antimicrobials failed to control the disease or bacterial overgrowth. Surgical resection was impossible because of the extent of the disease. Despite a temporary improvement with high steroid doses (100 mg prednisone/day, i.v.) and total parenteral nutrition, the patient died in cachexia after resumed p.o. feeding. The authors speculate on whether the disease might fit into the spectrum of the usually fatal disseminated eosinophilic collagen disease, also called hypereosinophilic syndrome, although several findings in this patient do not support this possibility.

4953 PEPTIDE TREATMENT OF POSTGASTRECTOMY OBSTRUCTION. (Eng.) Hiatt, R. B.; Goodman, I. (161 Fort Washington Ave., New York, NY 10032). *Arch. Surg.* 111(9):997-999; 1976.

The effect of coherin, a peptide isolated from the bovine neurohypophysis, in the treatment of life-threatening postgastrectomy obstruction was tested in 17 patients. Acute or chronic postgastrectomy obstruction occurred after Billroth II partial gastrectomy for ulcer (11 patients), Billroth I partial gastrectomy for ulcer (1), vagotomy and pyloroplasty for ulcer (1), gastrojejunostomy with vagotomy for ulcer (2), take-down of gastrojejunostomy-jejunal reflux (1), and esophagogastrectomy for carcinoma (1). On an average of 38 days after surgery, the patients received 100 μg of coherin, s.c., every 12 hr. Ten patients had acute physiological obstruction for an average of 38.6 days before coherin therapy, five had chronic obstruction with severe malnutrition for an average of 25 months before treatment, and two patients had chronic obstruction without severe malnutrition for an average of 5 months before treatment. In all 17 patients, the obstructive symptoms were relieved after the institution of coherin therapy, and the nasogastric tube could be permanently removed 4 days after treatment was begun. The patients with chronic obstruction and malnutrition required prolonged coherin therapy for continued, adequate p.o. alimentation. Three of these patients required coherin intermittently for an average of 2 yr; in two patients, coherin was required twice daily to prevent the symptoms of obstruction from returning. Coherin appears to be effective in the treatment of postgastrectomy obstruction.

4954 COLONIC INFUSION IN THE MANAGEMENT OF THE SHORT BOWEL SYNDROME. (Eng.) Rodgers, J. B.; Bernard, H. R.; Balint, J. A. (Albany Medical Coll., Albany, NY 12208). *Gastroenterology* 70(2):186-189; 1976.

The cases of two patients in whom colonic fluid infusion was used in the treatment of fluid and electrolyte imbalance, which resulted from the short bowel syndrome are presented. The first patient, a 44-yr-old woman, had initially undergone an end-to-side ileocolostomy for the treatment of regional ileitis. Eleven years later, she experienced severe diarrhea. At operation, the terminal 6 inches of residual small bowel were found to be grossly abnormal; the entire visualized colon was inflamed. The small bowel was divided just proximal to the area of gross involvement, and an ileostomy was fashioned. The end of the distal segment of ileum was brought to the anterior abdominal wall as a mucous fistula. During the next 2 postoperative months, the patient required continuous i.v. fluids and electrolyte replacement. After this period, the ileostomy outputs stabilized at 2-3 l/day, and the patient was gradually removed from i.v. therapy. Repeated episodes of fluid and electrolyte imbalance led to an attempt to supplement fluids by infusing saline (9 g NaCl and 4 g KCl/l tap water) into the colon via the mucous fistula. The patient has been able to administer this solution by herself, and has been able to tolerate infusions of 1.5 liters/24 hr in divided doses. She has remained in good fluid and electrolyte balance with normal renal function for the past 14 months. The second patient, a 39-yr-old man, had undergone resection of most of the small bowel for the treatment of bowel infarction resulting from a strangulated diaphragmatic hernia; the transverse colon

LIBRARY U. OF

had also been resected, and a right-sided colostomy had been constructed. The descending colon was vented with a mucous fistula. The postoperative management was complicated by the development of an enterocutaneous fistula, which drained 2-5 l/day, plus sepsis, renal failure, bleeding from gastric ulcers, and jaundice resulting from gallstones. The enterocutaneous fistula was closed, a cholecystectomy was performed, and the patient's symptoms resolved, with the exception of a fluid and electrolyte imbalance resulting from large fluid losses from the colostomy. The descending colon was infused with fluids (400 ml dextrose and saline) via the mucous fistula for 2 weeks, and the patient improved; the colostomy was subsequently closed successfully. It appears that colonic fluid infusion is useful in the management of patients with the short bowel syndrome. A simple diverting ileostomy seems preferable to colectomy in the surgical treatment for Crohn's disease.

4980 A COMPARISON OF HISTOCOMPATIBILITY ANTIGENS IN DERMATITIS HERPETIFORMIS AND ADULT COELIAC DISEASE. (Eng.) Seah, P. P.; Fry, L; Kearney, J. W.; Campbell, E.; Mowbray, J. F.; Stewart, J. S.; Hoffbrand, A. V. (St. Mary's Hosp., London W2 1NY, England). *Br. J. Dermatol.* 94(2):131-138; 1976.

Immunological processes in both dermatitis herpetiformis (DH) and adult celiac disease (ACD) were investigated, and the theory that DH patients can be divided according to the presence or absence of a macroscopic gut lesion plus an increased incidence of histocompatibility antigen, HL-A 8, was tested. The incidence of HL-A, 4a and 4b, was studied in 38 patients with DH, 36 patients with ACD, and 180 normal controls. The 4b antigen was found in all the DH and ACD patients. HL-A 8 was found in 89% of patients with ACD and in 79% of patients with DH. There was no significant difference in the incidence of HL-A 8 between those patients with DH whose small intestinal biopsies appeared macroscopically abnormal and those with a normal macroscopic appearance. These findings suggest that patients with DH form a single disease group. They do not support the previously postulated concept that there are two groups of patients with DH, one with an increased incidence of HL-A 8 antigen simi-

LIBRARY U.

lar to that in ACD with a gluten-sensitive enteropathy, and another with a normal incidence of HL-A 8 antigen and without enteropathy.

4981 SERUM LYSOZYME IN INFLAMMATORY BOWEL AND COELIAC DISEASE. (Eng.) Mallas, E.; Terry, J. M.; Asquith, P.; Cooke, W. T. (The General Hosp., Birmingham, England). *J. Clin. Pathol.* 29(7): 598-600; 1976.

The claims that serum lysozyme activity differentiates between Crohn's disease and ulcerative colitis and that serum lysozyme levels may serve as an index of disease activity were evaluated. Serum lysozyme levels were determined by a turbidometric method using egg white lysozyme in 100 patients with Crohn's disease, 86 with ulcerative colitis, 31 with celiac disease, and 38 normal controls. Although the levels in Crohn's disease (17.2 μg/ml) were significantly higher than those in ulcerative colitis (13.3 μg/ml, $p<0.001$), adult celiac disease (14.6 μg/ml, $p<0.025$), and controls (11.5 μg/ml, $p<0.001$), there was marked overlap between the diseased and control subjects. There were significant correlations ($p<0.001$) in both Crohn's disease and ulcerative colitis between seromucoids and albumin, albumin and hemoglobin, and seromucoids and hemoglobin. Lysozyme values correlated significantly with serum seromucoid levels ($p<0.001$) in Crohn's disease, but did not correlate in ulcerative colitis; lysozyme did not correlate with albumin or hemoglobin in either disease. It is concluded that serum lysozyme determinations are not useful in the differential diagnosis between Crohn's disease and ulcerative colitis, but that they may be valuable in assessing disease activity in Crohn's disease.

4982 RELATIONSHIP BETWEEN DISTURBANCE OF MICELLAR FORMATION AND STEATORRHEA. (Eng.) Ishikawa, M.; Masamune, O.; Yamada, H.; Takahashi, T.; Matsuura, S.; Torihata, K.; Gonai, T.; Nagasaki, A.; Tsuboi, M.; Yamagata, S. (Yamagata Univ. Sch. Medicine Yamagata, Japan). *Tohoku J. Exp. Med.* 118(Suppl.): 85-88; 1976.

Studies were carried out in 12 healthy subjects and 20 patients with steatorrhea to determine whether steatorrhea is caused by the impairment of micelle formation. Steatorrhea was associated with the malabsorption syndrome caused by chronic pancreatitis, pancreatectomy, gastrectomy, or ileal diseases, each in five patients. After each patient had ingested a test meal consisting of 30 g of corn oil, 60 g of skimmed milk, 60 g of glucose, and 400 ml of water, the jejunal contents were collected by intubation. The micellar phase was composed of 70.3 ± 15.8% and 62.6 ± 9.5% fatty acid in the controls and patients, resp. Monoglyceride accounted for 19.0 ± 10.0% and 21.9 ± 7.7% of the micellar phase in controls and patients, resp., while the micellar di- and triglyceride contents were much less (10.4 ± 8.7% and 15.5 ± 8.2%, resp.). The mean value of the ratio of fat content in the micellar phase to the total fat content was 76.9 ± 21.5% in 38 normal subjects. In contrast, the micellar fat ratio was decreased in the patients with malabsorption to 56.1 ± 20.3% in pancreatitis, 24.9 ± 20.8% in pancreatectomy, 50.0 ± 21.8% in gastrectomy, and 45.1 ± 14.2% in ileal disease. When values for micellar fat were plotted against those for fecal fat excretion in patients and controls, the percentage of fat in the micellar phase decreased as the fecal fat excretion increased ($r= 0.524$). The results indicate that the impairment of micelle formation causes a disturbance in intraluminal fat digestion, resulting in steatorrhea.

4983 INTESTINAL PERFUSION STUDIES IN TROPICAL SPRUE. 1. AMINO ACID AND DIPEPTIDE ABSORPTION. (Eng.) Hellier, M. D.; Radhakrishnan, A. N.; Ganapathy, V.; Mathan, V. I.; Baker, S. J. (Christian Medical Coll. Hosp., Vellore-632004, Tamil Nadu, India). *Gut* 17(7):511-516; 1976.

Intestinal absorption of glycine (20 μM), glycyl-glycine (10 μM) plus L-leucine (10 μM), and glycyl-L-leucine (10 μM) was studied by intestinal perfusion in 11 patients with tropical sprue and 10 age- and sex-matched controls. The patients with sprue had a significant reduction in the rate of absorption of glycine from a 20 μM solution, but there were no significant differences in the absorption of the other substances. The failure to demonstrate any difference in absorption is probably related to the low concentration of the substances relative to the maximum absorptive capacity of the intestine. The kinetic advantage of glycylglycine absorption compared with glycine absorption was maintained in the patients with sprue and the controls. The mean kinetic advantage for glycine from the dipeptide solution was 30% in controls and 34.5% in the patients with sprue. When the dipeptides were perfused, free amino acids appeared in the perfusate, presumably by back diffusion from the mucosal cells. In the case of glycyl-L-leucine, considerably more glycine and leucine were found in the perfusate in patients with sprue than in the control subjects. There was no correlation between peptide absorption and the concentration of total glycylglycine hydrolase and glycyl-L-leucine hydrolase, measured as combined brush border and cytosol enzymes. The concentrations of these enzymes were similar in both groups of subjects.

4984 WHIPPLE'S DISEASE: DEMONSTRATION BY IMMUNOFLUORESCENCE OF SIMILAR BACTERIAL ANTIGENS IN MACROPHAGES FROM THREE CASES. (Eng.) Keren, D. F.; Weisburger, W. R.; Yardley, J. H.; Salyer, W. R.; Arthur, R. R.; Charache, P. (Walter Reed Army Inst. Res., Washington, DC 20012). *Johns Hopkins Med. J.* 139(2):51-59; 1976.

The etiology of Whipple's disease was investigated in three patients by an immunofluorescence technique that can localize and help characterize bacterial antigens in tissue. Jejunal tissue specimens from the three patients with the disease, from three normal subjects, and from one patient with celiac-like disease were exposed to rabbit antibacterial grouping sera and then to fluorescein-conjugated antirabbit immunoglobulin g (IgG). Bacterial antigens were detected in the granules of the foamy macrophages from all patients with Whipple's disease. The macrophages in each case stained with several types of antibacterial grouping sera. Jejunal biopsies from the normal subjects and from the patient with celiac-like disease did not show significant reactions to any of the antisera. When these same antisera were reacted with homologous and heterologous bacteria, numerous cross-reactions were seen. However, each organism only reacted with certain antisera, resulting in a distinctive pattern of reaction that could identify it. If a different organism was present in each case of Whipple's disease, the antisera should give dissimilar reactions from case to case, but if the same type of microbe was present in each case, a similar pattern of reaction should be seen. In this study, the reactions were remarkably similar from case to case. These results suggest that a single, antigenically definable microorganism is present in the jejunal tissue of patients with Whipple's disease.

LARGE INTESTINE

4995 DOES BACTEREMIA FOLLOW COLONOSCOPY? (Eng.) Norfleet, R. G.; Mulholland, D. D.; Mitchell, P. D.; Philo, J.; Walters, E. W. (Marshfield Clinic, 1000 North Oak Ave., Marshfield, WI 54449). *Gastroenterology* 70(1):20-21; 1976.

To determine the risk of bacteremia from colonoscopy, blood specimens from 40 patients were cultured the day before laxative and enema preparation; right after such preparation; and 15 min, 1 hr, and 4 hr after colonoscopy. Bacteremia was not induced by either the preparation or the colonoscopy, which, in 27 patients, included polypectomy, biopsy, and/or fulgurations. It is concluded that the risk of bacteremia following colonoscopy is small, and antibiotic prophylaxis for patients with susceptible hearts is probably not needed.

4996 EFFECTS OF PROPHYLACTIC ANTIBIOTICS ON COLONIC HEALING.

(Eng.) LeVeen, H. H.; Wapnick, S.; Falk, G.; Olivas, O.; Bhat, D.; Gaurdre, M.; Patel, M. (Veterans Admin. Hosp., Brooklyn, NY 11209). *Am. J. Surg.* 131(1):47-53; 1976.

To investigate whether antibiotics favorably modify the healing of colonic wounds, the effect of antibiotic colon preparation on the tensile strength and morphologic appearance of colonic anastomoses was investigated in 50 dogs in which the midsigmoid colon was divided and anastomosed. Preparation with preoperative kanamycin (500 mg, 3 times daily for 3 days) offered a slight benefit over mechanical bowel cleansing. The addition of erythromycin (250 mg, 3 times daily for 3 days) and kanamycin to the preoperative bowel preparation significantly ($p<0.001$) improved the mean tensile strength of the healing colonic anastomosis (mean=228 gm in animals treated with kanamycin only; 277 gm in animals treated with both antibiotics). Continuation of erythromycin and kanamycin for 1 week postoperatively almost doubled the mean tensile strength of the healing anastomosis (319 gm). Continuation of erythromycin without kanamycin in the postoperative period provided little protection (mean tensile strength, 278 gm) over the preoperative administration of kanamycin and erythromycin. Histologic examination showed that erythromycin and kanamycin given during the pre- and postoperative periods changed the mode of healing from that of secondary intention to healing by first intention. The findings support the concept that soilage of the peritoneal cavity at the time of elective colon surgery is not as important as leakage caused by poor anastomotic healing. Antibiotic bowel preparation with kanamycin and erythromycin improves the healing of colonic anastomoses.

4997 SOME UNCOMMON ROENTGENOLOGIC FINDINGS ASSOCIATED WITH ACUTE PERFORATIVE APPENDICITIS.

(Eng.) Joffe, N. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Radiology* 110(2):301-305; 1974.

The cases of five patients with uncommon roentgenologic findings associated with acute perforative appendicitis are presented. In the first patient, a 30-yr-old man, there was a spontaneous occurrence of a cecosigmoid fistula. The appendiceal perforation presumably occurred at the time of a so-called episode of viral gastroenteritis 2 yr previously, as this was the only prior abdominal problem. In the second patient, a 10-yr-old girl, a preoperative abdominal radiograph revealed the presence of gas in the appendix. A barium study revealed a large collection of gas and fluid in the lesser sac, associated with generalized peritonitis and pus in the greater peritoneal sac. The presence of a gas and fluid collection in the lesser sac can be demonstrated by obtaining anteroposterior and lateral roentgenograms of the abdomen following opacification of the stomach with barium or Gastrografin. In the third patient, a 6-yr-old boy, a barium enema examination revealed a sharply circumscribed, smooth defect on the right posterior aspect of the distal sigmoid colon with stretching of the overlying mucosa; surgical exploration revealed a perforated appendix with a walled-off abscess adherent to and partly embedded within the wall of the sigmoid colon. A barium enema examination in the last patient, a 64-yr-old woman, revealed a filling of the appendix that communicated with an irregularly rounded cavity.
The pathologic findings suggested that this cavity was a walled-off abscess resulting from appendiceal perforation; this case demonstrates how so-called diverticula of the appendix may arise.

4998 ROENTGENOGRAPHIC FEATURES IN ANTIBIOTIC-ASSOCIATED PSEUDOMEMBRANOUS COLITIS.

(Eng.) Cho, K. J.; Ting, Y. M.; Chuang, V. P.; Lee, I. (Dept. Radiology, Univ. Michigan, Ann Arbor, MI 48132). *Australas. Radiol.* 20(1):38-41; 1976.

The radiologic findings in four cases of pseudomembranous colitis related to antibiotic therapy are reported. The antibiotics associated with the development of colitis included one or more of the following: clindamycin, gentamycin, vancomycin, colistin, ampicillin, and erythromycin. Barium enema showed a wide spectrum of roentgenographic features, ranging from mild, focal areas of mucosal irregularity to widespread involvement of the entire colon with multiple confluent pseudomembranes. The mucosal irregularity was caused by plaque-like pseudomembranes studding the mucosal surface. These varied in size and appeared as oval or rounded filling defects, mimicking pseudopolyps in air contrast studies. In profile, the pseudomembranes had a shaggy contour, simulating ulceration. Three patients showed nonobstructive dilation of the bowel, with an adynamic ileus gas pattern, and one of these had intramural gas in the cecum. Multiple areas of barium dissection under the pseudomembranes, and possibly under the mucosa, were seen in one patient. The diagnosis of pseudomembranous colitis was confirmed by sigmoidoscopy and biopsy.

4999 DIVERTICULAR DISORDERS OF THE COLON AND ASSOCIATED PATHOLOGY.

(Eng.) Berardi, R. S.; Siroospour, D. (Veterans Admin. Hosp., Des Moines, IA 50310). *Am. J. Proctol.* 27(2):45-54, 56; 1976.

The incidence of diseases associated with diverticular disorders of the colon was surveyed in 437 male patients. Diverticular disorders were divided into four types: asymptomatic diverticulosis was found in 309 patients (average age, 64.5 yr); diverticular disease occurred in 64 patients (average age, 65.2 yr); acute diverticulitis and its complications were seen in 32 patients (average age, 59.5 yr); and bleeding diverticulosis was found in 27 patients (average age, 59.5 yr). Associated pathology was found most commonly in the gastrointestinal tract (22.1%). Duodenal ulcer was the most common condition, and was found in 14.6% of the cases. Combined associated gastrointestinal pathology was found in 5.5% of the patients. The urogenital tract revealed pathology in 27.1% of the patients. The cardiovascular system was involved in 56.8% of the patients, while 19% had associated pathology of the respiratory system, and 15.8% had abdominal wall hernias. Diabetes mellitus was noted in 8.9% of the cases, and obesity in 8.2%. Anxiety depression was noted in 8.2% of the patients and accounted for almost 50% of the central nervous system involvements. The incidence of associated anal and colorectal pathology was higher in bleeding diverticulosis than in other types of diverticular disorders (25.9% versus 13.0%). Hypertension was found in 18.5% of the patients with bleeding diverticulosis, compared to 12.8% of all patients and 11.8% of all symptomatic patients. It is concluded that no common etiopathogenetic factor or factors is suggested between diverticular disorders of the colon and associated disease, over and above that which appears to be due to coincidence, chance, age of the patient, and/or anticipated incidence of the disease in the patient population studied.

LIBRARY U. [illegible]

5000 DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE BY PUNCH BIOPSY OF RECTUM. (Eng.) Pease, P. W. B.; Corkery, J. J.; Cameron, A. H. (Birmingham Children's Hosp., Ladywood Middleway, Ladywood, Birmingham B16 8ET, England). *Arch. Dis. Child.* 51(7): 541-543; 1976.

The safety and reliability of rectal punch biopsy in the diagnosis of Hirschsprung's disease were evaluated by examining 234 punch biopsy specimens from the rectum and colon of 112 children (aged < 1 week-12 yr). The procedure was carried out without bowel preparation, and a standard Chevalier-Jackson vocal cord biopsy forceps was used. Depending on the age of the patient, the samples were taken 2-3 cm above the dentate line to avoid the normal hypoganglionic zone. Biopsy was performed under general anesthesia in 47 patients. The specimens were 4-5 mm in diameter and were rounded or dome-shaped. They were fixed in buffered 10% formalin and processed to paraffin. Ganglion cells were considered absent if none were seen in 50 serial sections that included an adequate amount of submucosa; in addition, a diagnosis of Hirschsprung's disease was rejected unless the aganglionic sections also showed thickened nerve trunks. In 94% of the patients, the diagnosis of Hirschsprung's disease was confirmed or refuted by the first biopsy; a second biopsy was required in four patients. Hirschsprung's disease was diagnosed in 31% of the 112 patients, and all diagnoses were confirmed by histological examination of specimens resected during therapeutic pull-through operations. In four patients, the biopsy specimen included muscle as well as mucosa and submucosa; only one of these patients developed a serious complication (a large pelvic hematoma due to a combination of the biopsy procedure and the onset of hemorrhagic disease of the newborn and omission of preoperative vitamin K). The authors believe that full thickness rectal biopsy is no longer necessary or justified in the diagnosis of Hirschsprung's disease, and that punch biopsy is simple, safe, and reliable.

5001 PSYCHIATRIC ILLNESS AND THE IRRITABLE BOWEL SYNDROME: PRACTICAL IMPLICATIONS FOR THE PRIMARY PHYSICIAN. (Eng.) Young, S. J.; Alpers, D. H.; Norland, C. C.; Woodruff, R. A., Jr. (Washington Univ. Sch. Medicine, St. Louis, MO). *Gastroenterology* 70(2):162-166; 1976.

The results of a previous study that linked the irritable bowel syndrome and psychiatric illnesses were confirmed in a group of patients with the syndrome and in a control group. Twenty-nine consecutive outpatients (from an internal medicine group practice) with irritable bowel syndrome were given structured psychiatric interviews, as were 33 consecutive medical controls who did not have irritable bowel syndrome. Seventy-two percent of irritable bowel syndrome subjects had psychiatric illness, with hysteria (17%) and depression (17%) the most prevalent syndromes. Only 18% of controls had psychiatric illness. The primary physician made an accurate psychiatric assessment in only 28% of the subjects. An awareness of the patient's psychiatric illness is necessary for the physician to provide effective treatment, and to spare the patient needless medications, hospitalizations, and surgery.

5002 ACUTE DILATION OF THE COLON IN MALIGNANT LYMPHOMA. (Eng.) Wagonfeld, J. B.; Baker, A. L.; Reed, J. S.; Platz, C. E.; Kirsner, J. B. (Univ. Chicago, Pritzker Sch. Medicine, 950 E. 59th St., Box 400, Chicago, IL 60637). *Gastroenterology* 70(2):264-267; 1976.

The case of a 66-yr-old man with malignant lymphoma who developed acute dilatation of the colon with signs of systemic toxicity is presented. Although barium contrast x-rays taken previously were interpreted as consistent with granulomatous colitis, rectal biopsy revealed features characteristic of malignant lymphoma of the poorly differentiated lymphocytic type. Bone marrow and lymph nodes were also involved. The onset of dilatation was temporally related to theraphy with opiates and anticholinergics, and the acute episode was resolved with nasogastric suction, i.v. fluids, albumin, and antibiotics. This case suggests that this complication can occur in a patient without the destruction of the muscularis propria by deep ulcerations or degeneration of the myenteric plexus, which are seen in ulcerative colitis and granulomatous colitis.

5003 ELEVATED SERUM ACID PHOSPHATASE LEVELS WITH RECTAL CARCINOID TUMOR. (Eng.) Davidson, E. D.; McDougal, W. S. (Joseph B. Whitehead Dept. Surgery, Emory Univ., Atlanta, GA). *Gastroenterology* 70(1):114-116; 1976.

The case of a 52-yr-old man in whom a marked elevated serum acid phosphatase level was found in combination with a rectal carcinoid tumor with liver metastases is reported. The serum acid phosphatase level ranged from 2.5 to 5 IU. Tissue assays of the tumor, liver metastasis, and uninvolved liver revealed elevated acid phosphatase levels of 50.0, 74.5, and 3.7 mg phosphorus/mg tissue protein/hr, resp., when thymophthalein was used as a substrate in the assay and 152, 177, and 11 mM phosphate/mg tissue protein/min, resp., when β-glycerophosphate was used as a substrate. The patient also had elevated plasma serotonin (0.26 μg/ml) and urinary 5-hydroxyindole acetic acid (18 mg/24 hr) levels, and did not exhibit the carcinoid syndrome. Autopsy showed no prostate cancer or metastatic bone lesions. Serum acid phosphatase elevation may occur with carcinoid lesions of the rectum.

5004 COMPARISON OF 5-FLUOROURACIL WITH 5-FLUOROURACIL, CYCLOPHOSPHAMIDE, AND METHOTREXATE IN METASTATIC COLORECTAL CARCINOMA.

(Eng.) Richards, F., II; Pajak, T. L.; Cooper, M. R.; Spurr, C. L. (Bowman Gray Sch. Medicine, Wake Forrest Univ., Winston-Salem, NC 27103). *Cancer* 36(5):1589-1592; 1975.

The response of colorectal carcinoma to 5-fluorouracil (5-FU, 38 patients) or to a combination chemotherapy (CC, 38 patients) using 5-FU, cyclophosphamide (CP), and methotrexate (MTX). An additonal 16 patients were treated with CC after failing to respond to FU alone. Therapeutic effects and effects on survival were compared. 5-FU was given at 12 mg/kg, i.v., on days 1-5, followed 10-17 days later by maintenance therapy, which continued at weekly intervals for at least 6 treatment courses. The CC group received the same dose of 5-FU plus 10 mg/kg CP, i.v., and 0.1 mg/kg, i.v., MTX on day 1. Maintenance therapy began 10-17 days later. An objective response was defined as a 50% decrease in the product of the longest perpendicular diameters of the indicator lesions. Ten patients receiving 5-FU improved, and eight had an objective response; 10 patients in the CC group improved, and 7 had an objective response. Neither the response rates nor the duration were statistically different in the two groups. There was no significant difference between the survival of the two groups (6.5 and 6.8 months). Patients with impaired liver function did less well than patients with good liver function in both groups. More toxicity was experienced by patients receiving CC compared to 5-FU, but this was significant only for anemia and leukopenia. Six of 16 patients who switched from 5-FU to CC responded favorably. It is recommended that patients with metastatic colorectal carcinoma initially be given 5-FU alone (unless they have pulmonary metastases), and if they relapse or do not respond to this treatment, a trial with CC is warranted.

5005 HEPATIC ARTERY LIGATION AND 5-FLUOROURACIL INFUSION FOR METASTATIC COLON CARCINOMA AND PRIMARY HEPATOMA.

(Eng.) Ramming, K. P.; Sparks, F. C.; Eilber, F. R.; Holmes, E. C.; Morton, D. L. (54-140 Center Health Sciences, Univ. California Los Angeles, Los Angeles, CA 90024). *Am. J. Surg.* 132(2):236-242; 1976.

The results of treating nine patients with extensive bilateral hepatic metastases of colorectal cancer with hepatic artery ligation and continuous infusion of 5-fluorouracil (5-FU) are reported. Silastic catheters were inserted into the hepatic artery at laparotomy, and continuous perfusion was effected by a Sigmamotor pump. There was no operative mortality or morbidity, and drug toxicity was acceptable. The dosage averaged 10 mg/kg/day (2.5-14 mg/kg/day) for an average of 63 days. Liver function in all patients returned to preoperative values within 2 weeks, and four patients showed improvement of preoperative liver function for 3-6 months after perfusion. Two patients had palpable regressions lasting 5 months or more, and one patient had a slight palpable regression for 2 months. The five who died had a mean survival of 10.4 months after therapy. Eight of the nine patients showed significant clinical improvement following treatment. Seven patients with irresectable primary liver carcinoma were treated with continuous 5-FU infusion. A Silastic catheter was placed into the hepatic artery via the gastroduodenal artery at laparotomy; ligation of the hepatic artery was not performed. There was no operative mortality or morbidity. The dosage averaged 10 mg/kg/day for an average of 140 days. Significant clinical improvement was noted in six of the seven patients, although this did not correlate with improvement of hepatic function. All six responding patients are still living (mean survival, 14 months). Prolongation of life with hepatic artery infusion of 5-FU has been significantly better than with any previously reported chemotherapy for this disease.

5006 FECAL STEROIDS AND BACTERIAL FLORA IN PATIENTS WITH POLYPOSIS COLI.

(Eng.) Watne, A. L.; Lai, H.-Y. L.; Mance, T.; Core, S. (West Virginia Univ. Medical Center, Morgantown, WV 26506). *Am. J. Surg.* 131(1):42-46; 1976.

Fecal neutral and acid steroids and bacterial flora were studied in 9 patients with untreated polyposis coli, in 6 patients with polyposis coli who had undergone ileorectostomy at least 1 month before the study, and in 14 normal controls. The nine untreated patients showed higher mean concentrations of cholesterol, cholic acid, and chenodeoxycholic acid (14.69, 0.6, and 0.8 mg/g dry weight, resp.) than the controls (6.0, 0, and 0 mg/g, resp.). These levels in the six treated patients increased even more after ileorectostomy (preoperative: 12.1, 0.6, and 0.8 mg/g, resp.; postoperative: 17, 2.4, and 2.1 mg/g, resp.). The bacterial flora of the patients with polyposis coli showed an anaerobe/aerobe ratio of 2.7:1, with a relative increase in clostridia and bifidobacteria and a decrease in eubacteria and bacteroides. After ileorectostomy, the clostridia disappeared, as did ruminococcus, peptostreptococcus, and fusobacteria; eubacteria and lactobacilli decreased and bifidobacteria and bacteroides increased. Eubacteria showed a decrease from normal in the pre- and postoperative patients with polyposis coli, and this paralleled a decrease in coprostanol (preoperative, 6.5 mg/g; postoperative, 0 mg/g). The fact that the patients with polyposis coli excrete a significantly increased amount of cholesterol compared to coprostanol suggests some alteration in the fecal flora. A decrease in stool transit time resulting in diarrhea in these patients may be due to high

LIBRARY U.

levels of chenodeoxycholic acid. After ileorectostomy, the transit time in two patients decreased from a preoperative average of 19.4 hr to 14.2 hr.

Ulcerative Colitis

5033 CIRCULATING ANTIBODIES TO BOVINE ALBUMIN IN ULCERATIVE COLITIS AND CROHN'S DISEASE: CHARACTERIZATION OF THE ANTIBODY RESPONSE. (Eng.) Falchuk, K. R.; Isselbacher, K. J. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Gastroenterology* 70(1):5-8; 1976.

The presence of antibodies against bovine serum albumin (BSA) was investigated in the serum of 28 normal subjects and in 70 patients with inflammatory bowel disease and celiac disease. Antibodies to BSA were demonstrated in 28 of 30 patients with ulcerative colitis, 30 of 35 with Crohn's disease, 5 with untreated celiac disease, and in 12 normal subjects. In patients with inflammatory bowel disease, antibodies to BSA were present in greater amounts in those with severe and moderate disease than in those with mild disease. Moreover, in those patients with high titers of circulating antibody, the serum anti-BSA activity was always associated with immunoglobulin G and sometimes with immunoglobulin A. These findings suggest that an increased absorption of antigenic material and stimulation of antibody production may occur in association with intestinal mucosal damage, not only in ulcerative colitis and celiac disease, but also in Crohn's disease.

5034 UROLOGIC COMPLICATIONS OF INFLAMMATORY BOWEL DISEASE. (Eng.) Shield, D. E.; Lytton, B; Weiss, R. M.; Schiff, M., Jr. (Yale Univ. Sch. Medicine, New Haven, CT). *J. Urol.* 115(6):701-706; 1976.

Urinary complications were examined in 233 patients with inflammatory bowel disease. Because of changing concepts in inflammatory bowel disease, no attempt was made to correlate specific subclasses with urinary complications. Enterovesical fistulas de-

LIBRARY U. C. [illegible]

veloped in 9 patients, with a mean duration of symptoms of 4.4 yr (range, 3 months-13 yr). Twenty patients had urinary tract calculi, with an average duration of symptoms of 9.6 yr. Rectovaginal complications occurred in 12 patients, while 1 patient each experienced neurogenic bladder, impotence, urethrocutaneous fistula, bladder calculi, and urethral stricture. Enterovesical fistulas may begin with formation of sinus tracts from the inflamed segment of bowel next to the bladder. This abscess cavity leads eventually to the irritative bladder symptoms and pyuria. Excision of the diseased bowel and resection of the involved portion of the bladder would be the treatment of choice. This procedure resulted in correction of the enterovesical fistulas in six of seven patients. The incidence of urinary calculi was especially high in patients who have had ileostomies (12.9%). The majority of calculi were composed of calcium salts. The authors suggest that urologic evaluation should be included in the long-term management of patients with inflammatory bowel disease.

5035 FATE OF THE RETAINED RECTUM AFTER SUBTOTAL COLECTOMY FOR INFLAMMATORY DISEASE OF THE COLON.

(Eng.) Binder, S. C.; Miller, H. H.; Deterling, R. A., Jr. (Tufts New England Medical Center, 171 Harrison Ave., Boston, MA 02111). *Am. J. Surg.* 131(2):201-203; 1976.

A retrospective review of 49 patients who survived subtotal colectomy for inflammatory disease involving both the colon and rectum was undertaken to evaluate the practice of retaining the rectum in patients requiring colectomy for inflammatory bowel disease. There were 26 male patients, and the ages of all patients ranged from 9 to 72 yr. Patients with granulomatous ileocolitis and granulomatous colitis not involving the rectum were excluded. Eleven patients have retained the rectal remnant from 1 to 14 yr, although only 2 of these patients had a successful ileoproctostomy. Of the remaining 38 patients, 2 patients with ulcerative colitis of 25- and 13-yr duration had peritoneal carcinomatosis secondary to colonic cancer at the time of colectomy and died postoperatively at 8 months and 2 yr, resp. Of the 36 other patients, 33 underwent subsequent combined abdominoperineal resection of the rectum after having persistent symptoms related to the retained rectum; 3 patients underwent the operation without these symptoms. All 36 had persistent active colitis in the rectum. By the end of 5 yr, only 6 of the 36 patients who eventually underwent abdominoperineal resection still retained the defunctioned rectal remnant. There were no postoperative deaths after subsequent combined abdominoperineal resection, but the rate of postoperative complications was 44.4%, and hospitalization averaged 17.5 days. For the patient whose rectum, along with the rest of the colon, is substantially diseased, one-stage total proctocolectomy is the preferred operation.

5036 COMPARATIVE MAPPING OF THE LOCAL DISTRIBUTION OF IMMUNOGLOBULIN-CONTAINING CELLS IN ULCERATIVE COLITIS AND CROHN'S DISEASE OF THE COLON.

(Eng.) Baklien, K.; Brandtzaeg, P. (Inst. Pathology, Rikshospitalet, Oslo 1, Norway). *Clin. Exp. Immunol.* 22(2):197-209; 1975.

The local B-cell responses in Crohn's disease were studied by determining the occurrence and distribution of immunoglobulin (Ig)-containing cells throughout the various layers of the inflamed bowel wall. Inflamed colonic tissue was obtained from 6 patients with Crohn's disease and from 11 patients with ulcerative colitis, and the responses of the Ig-containing cells were compared by paired immunohistochemistry. In the Crohn mucosa with persisting glands, the total cell count was, on the average, more than three times higher than controls. The numbers of IgA, IgM, and IgG immunocytes were increased 2.0, 4.8, and 28.6 times, resp. Only 0-2 IgD- and IgE-containing cells were generally found in each section. No consistent differences in the mucosal response pattern were revealed when Crohn's disease was compared with ulcerative colitis. The deeper layers of the bowel wall were infiltrated by immunocytes (IgG cells comprising about 80%) in both diseases. Immunoglobulin-containing cells in the muscularis propria and subserosa were characteristically found in Crohn's disease. There was no indication of a primary defect in the secretory Ig system, which appeared to be normal in areas with intact glands. The pronounced local humoral immune response, particularly that involving IgG, might be of pathogenetic importance by aggravating and perpetuating the inflammatory bowel disease.

5037 THE ELECTRICAL POTENTIAL DIFFERENCE ACROSS HUMAN ILEOSTOMY MUCOSA.

(Eng.) Isaacs, P. E. T.; Horth, C. E.; Turnberg, L. A. (Manchester Royal Infirmary, Manchester, England). *Gastroenterology* 70(1):52-58; 1976.

To elucidate the mechanisms underlying the change in ileal absorptive capacity that occurs after ileostomy, the potential difference (PD) between ileostomy lumen and forearm skin was measured in 28 subjects, 19 of whom had had ulcerative colitis and 9, Crohn's disease. The mean PD at 3-5 cm from the tip of the ileostomy was 17.2 ± 0.6 mV (SEM) in the ulcerative colitis group and 16.5 ± 1.1 mV in the Crohn's disease group. The PD was highest at the tips of ileostomies, and decreased to about half the tip level at 10-15 cm deep to the tip. Even at this distance from the tip, PD was apparently higher than values reported in normal ileum. PD rose during the first few weeks after colectomy and reached a stable value at about 2 months. Plasma aldosterone levels were normal in six subjects, but the administration of spironolactone (100 or 200 mg/day, p.o.) caused a fall in PD. These apparently conflicting observations suggest that the raised PD was maintained, at least in part, as a response to normal levels of aldosterone and an increased sensitivity to aldosterone by ileal mucosa near an ileostomy is postulated. A significant correlation between PD and salivary Na to K ratios also supports a relationship between PD and aldosterone levels. Another patient, with a jejunostomy, also had a high transmucosal PD, suggesting that jejunal mucosa may respond in a similar manner. No evidence in favor of active K secretion was discovered, because

K concentrations in ileostomy ejecta were no greater than those that could be predicted as a passive response to the PD, except in some subjects during the first week after surgery.

5038 SELECTIVE INTRAARTERIAL STEROID INJECTION IN ULCERATIVE COLITIS. (Eng.) Hiramatsu, K.; Asakura, H.; Baba, S. (Sch. Medicine, Keio Univ., Tokyo, Japan). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 17(3):299-304; 1976.

The angiographic findings in 11 patients with ulcerative colitis, 10 of whom had received prednisolone intraarterially via the catheter, were compared with those in 32 control patients. For the examination, 35 ml of 76% Urografin were injected into the superior mesenteric artery, and 15 ml were injected into the inferior mesenteric artery (7 ml/sec). Prednisolone (10-25 mg) was injected into the inferior mesenteric artery in 10 patients, and in 7 patients it was injected into both the inferior and superior mesenteric arteries. There was a loss of the normal tapering of the vasa recta in all patients; intense capillary filling was observed in nine cases, and early venous filling in five. The mean width of the inferior mesenteric artery in patients with ulcerative colitis (5.7 mm) was significantly greater than that in the controls (4.1 mm). In the patients treated with steroids, moderate improvement occurred within 24 hr in four cases, and marked improvement occurred in five. The clinical symptoms remained unchanged in only one patient, despite a second injection into the superior and inferior mesenteric arteries.

5039 PYODERMA GANGRENOSUM IN ULCERATIVE COLITIS: PREVENTION OF THE GANGRENOUS COMPONENT. (Eng.) Gelernt, I. M.; Kreel, I. (Mount Sinai Sch. Medicine, Fifth Ave. and 100 St., New York, NY 10029). *Mt. Sinai J. Med. N.Y.* 43(4):467-470; 1976.

The cases of two patients with ulcerative colitis-associated pyoderma gangrenosum that was successfully treated with cyproheptadine are reported. The first patient, a 15-yr-old boy with a 9-yr history of ulcerative colitis, had diffuse pyoderma gangrenosum lesions on both lower limbs, the trunk, and the left arm. Within 24 hr of onset, several lesions had already become gangrenous and others were ecchymotic with gangrene imminent. Prednisone was increased from 15 to 30 mg daily, and cyproheptadine hydrochloride (4 mg, 4 x daily) therapy was begun. No lesion, which was not already gangrenous, progressed to necrosis, and the erythematous early lesions resolved within 3 days. The ecchymotic lesions cleared after about 10 days. The second patient, a 20-yr-old woman with an 11-yr history of ulcerative colitis, had exacerbated colonic symptoms and a single pretibial lesion. Four years previously, pyoderma gangrenosum had developed on the leg and had taken 8 months to resolve, despite increased steroid doses. During the present episode, the lesion completely disappeared 6 days after the first dose of cyproheptadine hydrochloride. The gangrenous phase of the pyoderma lesion in ulcerative colitis can be prevented with early administration of cyproheptadine. This drug is of special value in diseases characterized by frequent rectal bleeding; it prevents platelet thrombi in vessels, the effect is rapid, and it does not produce bleeding diathesis. Pyoderma lesions will progress to early resolution if the ischemic ulcer is avoided.

PANCREAS

5044 THE RISK AND ACCURACY OF PANCREATIC BIOPSY. (Eng.) Lightwood, R.; Reber, H. A.; Way, L. W. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Am. J. Surg.* 132(2):189-194; 1976.

The risk and accuracy of pancreatic biopsy were evaluated in 171 patients. The indications for surgery were obstructive jaundice (75 patients), suspected tumor (52), abdominal pain (11), chronic pancreatitis (12), and miscellaneous other diagnoses (15). The procedure produced complications (hemorrhage, pancreatitis, or duodenal leak) in eight patients and death in three of these. The diagnosis was confirmed in 86% of the cases, but was falsely negative in 14% of pancreatic cancers. Of the 136 direct wedge biopsies performed, 3% resulted in complications and none resulted in death. Of the 22 direct needle biopsies, 14% produced complications and 9% resulted in death. Ten percent of 19 transduodenal biopsies resulted in complications, and there was a 5% mortality rate. Wedge biopsy was used in 77 of 87 biopsies in cancer patients, and produced false-negative results 10 times (13%). The other 10 biopsies were done with a Vim-Silverman needle, and false-negative occurred in 5. Transduodenal biopsy was accurate for all except one patient. Wedge biopsy appeared preferable to needle biopsy, except for periampullary lesions in which transduodenal needle biopsy was best. When the biopsy incision transected a pancreatic duct, suture ligation and drainage avoided complications. Open transduodenal biopsy of periampullary lesions was reliable, but the duodenotomy closure leaked in 10% of the cases. Pancreatic biopsy with confirmation of malignancy should precede pancreaticoduodenectomy in most cases of suspected pancreatic cancer.

5045 PANCREATIC SECRETION IN PATIENTS WITH CHRONIC RENAL FAILURE. (Ger.) Otte, M.; Thurmayr, R.; Dobbelstein, H.; Stahlheber, H.; Forell, M. M. (Med. Klink., Univ. Munich, Munich, W. Germany). *Verh. Dtsch. Ges. Inn. Med.* 80:541-544; 1974.

Parameters of pancreas secretion were studied in 15 patients with advanced chronic renal failure (glomerulonephritis, pyelonephritis, and interstitial nephritis due to phenacetin abuse), and compared with similar findings in normal subjects and in patients with chronic relapsing pancreatitis, chronic calcereous pancreatitis, carcinoma of the pancreas, and chronic and acute duodenal ulcer. The Wilcoxon test and multivariate discrimination analysis were used for the statistical evaluation of the data. Following stimulation of pancreas secretion with cholecystokinin, secretin, ox bile extract, and their combinations, the normal maximal bicarbonate concentration was measured in the duodenal juice in the patients with chronic renal failure despite partly marked serum acidosis. The trypsin and lipase levels in the duodenal juice were normal in most patients, while the amylase level differed significantly from that of normal subjects. The serum lipase levels increased following stimulation in almost all cases. The multivariate statistical analysis indicates that patients with chronic renal insufficiceny show a disease-specific pancreatic secretion, which is neither normal nor typical for chronic pancreatitis or pancreatic carcinoma, but which is similar to that observed in duodenal ulcer.

5046 ATTEMPTED RETROGRADE CANNULATION OF THE AMPULLA: A PROBABLE CAUSE OF MASS IN THE PANCREAS. (Eng.) Bloom, G. P.; Fromm, D.; Rosenberg, S.; Goldman, H. (Hartford Hosp., Hartford, CT). *Ann. Surg.* 183(2):107-108; 1976.

Two cases of focal asymptomatic pancreatitis following attempted retrograde cannulation of the ampulla of Vater, which presumably produced a mass involving the head of the pancreas, are described. Serum amylase rose to 229 U following unsuccessful cannulation in the first patient, a 71-yr-old woman with gallstones and a history of spironolactone exposure. A focal mass with no evidence of fat necrosis or surrounding edema was found at laparotomy in the head of the pancreas. A pancreatoduodenectomy was performed, because the lesion grossly resembled carcinoma of the head of the pancreas; however, microscopic sections revealed acute interstitial pancreatitis limited to the head of the pancreas. The second patient, a 64-yr-old woman, had normal amylase levels before and after the unsuccessful procedure, but a 3 x 3 cm, firm localized mass with surrounding mild edema was found in the head of the pancreas; it resembled carcinoma, but dissection revealed a collapsed distal common duct. An operative cholangiogram demonstrated obstruction at the junction of both common hepatic ducts and a normal common duct, with free flow into the duodenum distally. Biopsy of the bifurcation of the hepatic duct showed primary adenocarcinoma. It is concluded that manipulations associated with the attempted retrograde cannulation of the ampulla may produce a focal inflammatory reaction in the head of the pancreas.

Pancreatitis

5054 PROGNOSTIC SIGNS AND NONOPERATIVE PERITONEAL LAVAGE IN ACUTE PANCREATITIS.

Eng.) Ranson, J. H. C.; Rifkind, K. M.; Turner, T. W. (New York Univ. Medical Center, New York, NY). *Surg. Gynecol. Obstet.* 143(2):209-219; 1976.

n on-going clinical study was undertaken in 300 consecutive patients with acute pancreatitis to evaluate methods for the early identification of this disease and to assess the influence of treatment on its course. Pancreatitis was associated with alcoholism in 207 patients, biliary tract disease in 51 patients and other conditions in 42. Twenty-two patients died, and an additional 34 patients required more than 1 week of treatment in intensive care. Retrospective analysis of the first 100 patients identified 11 objective findings that correlated with the occurrence of serious illness or death. They were on admission: age over 55 yrs, a blood glucose level over 200 mg%, a WBC count over 16,000/mm^3, a serum lactic dehydrogenase level over 350 IU/l, and an SGOT level over 250 Sigma Frankel U. During the initial 48 hr of therapy, the findings were hematocrit value decreased over 10 percentage points, serum calcium level below 8 mg%, base deficit over 4 mEq/l, a blood urea nitrogen level increase over 5 mg%, estimated fluid sequestration over 6 l, and arterial oxygen tension less than 60 mm of mercury. Prospective application of these signs in the latter 200 patients permitted the accurate early identification of those with severe pancreatitis. Only 1 of 162 patients with fewer than three of these early features was seriously ill or died, while 24 of 38 patients with three or more early positive findings were seriously ill or died. The objective early identification of patients with severe pancreatitis permits more vigorous management of this group and provides a basis for the selection of patients for the evaluation of proposed improved therapies. Percutaneous peritoneal dialysis in severe pancreatitis was evaluated in 10 patients with three or more positive early signs who were randomly assigned to dialysis or continued conventional care. Morbidity was strikingly reduced in patients who underwent dialysis. Death or more than 9 days of intensive care occurred in two of five patients who did not receive dialysis, while all five patients having dialysis recovered after fewer than 9 days of intensive care treatment. Serious illness or death occurred in 31 of the first 100 patients. There has been a similar fall in mortality from 15.0 to 3.5%. Factors that may contribute to this improvement include the objective early identification of patients with severe disease, the avoidance of early laparotomy whenever practical, the prolongation of nasogastric suction until all evidence of pancreatic inflammation has resolved, careful monitoring of respiratory function, and early treatment of pulmonary complications and peritoneal dialysis in patients with severe disease.

5055 A STUDY OF AUTOPSIES UPON 116 PATIENTS WITH ACUTE PANCREATITIS.

(Eng.) Storck, G.; Pettersson, G.; Edlund, Y. (Dept. Surgery III, Univ. Goteborg, Goteborg, Sweden). *Surg. Gynecol. Obstet.* 143(2):241-245; 1976.

The necropsy findings in 116 patients with fatal, acute pancreatitis were analyzed with special attention to hepatic dysfunction. This series includes the total fatalities caused by the disease between 1956 and 1970; all but two patients died in the first attack of acute pancreatitis. The patients were divided into four etiologic groups: gallstone disease, 43%; alcoholism, 25%; disease of idiopathic origin, 18%; and diseases originating from abdominal operations, 14%. Over the three 5-yr periods (1956-1960, 1961-1965, and 1966-1970), the frequency of alcohol abuse as a predisposing factor increased, while gallstone disease showed a corresponding decrease. About 75% of the patients had hyperbilirubinemia (4.9 mg/100 ml). Half of these showed signs of cholestasis. Macroscopic steatosis of the liver was recorded in 62% of the alcohol addicts and in about 25% of the patients in the other etiologic groups. Shock and late sequelae of shock were the dominating immediate causes of death in 72% of the cases. About 50% of the fatalities occurred within the first week. Most of these early deaths were caused by intractable circulatory failure. Early death was most commonly caused by alcoholism, followed in frequency by gallstone disease. It is possible that impaired hepatic function contributes to the fatal outcome in both the early and late phases of the disease.

5056 THE MECHANISM OF INCREASED RENAL CLEARANCE OF AMYLASE IN ACUTE PANCREATITIS.

(Eng.) Warshaw, A. L.; Lee, K.-H. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 71(3):388-391; 1976.

A study was undertaken to determine whether the increased amylase clearance in pancreatitis is a function of preferential clearance of isoamylases of pancreatic origin, metabolism of circulating amylases to a more readily excreted form, or greater renal permeability to all amylases. Amylase isoenzymes, separated by polyacrylamide gel electrophoresis, were measured in 25 normal subjects (mean amylase to creatinine clearance ratio, 3.0%), 15 patients with acute pancreatitis (mean clearance ratio, 9.5%; $p<0.0001$), and 6 patients with hyperamylasemia due to common duct stones (mean clearance ratio, 4.0%). In normal serum and urine, two isoamylases (P_1 and P_2) resembling pancreatic isoenzymes and three isoamylases (S_1, S_2, and S_3) resembling salivary isoenzymes appeared regularly. Salivary amylases predominated in the serum, but pancreatic amylases predominated in urine. This finding supports the hypothesis that the renal clearance of pancreatic amylases exceeds that of salivary amylases under normal conditions. In patients with pancreatitis or common duct stones, essentially all of the increased amylase activity in serum and urine was due to pancreatic isoamylases (P_1 and P_2) in their normal proportions. No new or altered amylase isoenzymes were detected. The fraction of pancreatic amylases in the serum or urine was identical for the two diseases. As the difference in amylase to creatinine clearance ratios observed between the two groups of patients was not a function of different amylases isoenzymes presented in the kidney, it is concluded that the increased amylase clearance in acute pancreatitis is caused by an alteration of renal transfer of amylase, either at the glomerulus or tubule.

5057 PANCREATIC ABSCESS FOLLOWING ACUTE PANCREATITIS. (Eng.) Holden, J. L.; Berne, T. V.; Rosoff, L., Sr. (Univ. Southern California Sch. Medicine, Los Angeles, CA). *Arch. Surg.* 111(8): 858-861; 1976.

The records of 28 patients who were treated by surgical drainage for pancreatic abscess following acute pancreatitis were analyzed to evaluate the use of the drainage procedure. There was a lull in the clinical course of the antecedent pancreatitis prior to the time of surgical drainage in 70% of the cases. Despite an aggressive surgical approach, there were major postoperative problems in 26 patients. Sepsis persisted in 14 patients. Major gastrointestinal hemorrhage occurred in 7 patients, intra-abdominal bleeding in 9 patients, and fistulization in 13 patients. Fourteen patients died. The operative treatment of pancreatic abscess must be aggressive and persistent. In addition to extensive drainage with soft sump drains, pressure against bowel or major vessels, must be avoided. Reoperation should be considered if postoperative improvement is not sustained.

5058 MARKED ALKALINE PHOSPHATASE ELEVATION WITH PARTIAL COMMON BILE DUCT OBSTRUCTION DUE TO CALCIFIC PANCREATITIS. (Eng.) Snape, W. J., Jr.; Long, W. B.; Trotman, B. W.; Marin, G. A.; Czaja, A. J. (Philadelphia General Hosp., 700 Civic Center Blvd., Philadelphia, PA 19104). *Gastroenterology* 70(1):70-73; 1976.

A syndrome of partial common bile duct obstruction and marked elevation in serum alkaline phosphatase occurring in six male alcoholic patients with calcific pancreatitis was characterized. A marked elevation in serum alkaline phosphatase (105-3,275 mU/ml) was associated with minimal, if any, elevation in serum bilirubin (0.2-8.6 mg/100 ml) in each patient. In four patients tested for BSP retention (45 min), the level was less than 5% in three patients and 7% in one. In all cases, the alkaline phosphatase was hepatic in origin, and i.v. or operative cholangiography showed a dilated common bile duct. Liver biopsy showed canalicular bile stasis in four patients and bile duct proliferation in two patients. This study demonstrates that calcific pancreatitis may cause partial bile duct obstruction, which differentially increases serum alkaline phosphatase without altering bilirubin or BSP excretion.

5059 ULTRASTRUCTURAL STUDIES IN CHRONIC HUMAN PANCREATITIS. (Ita.) Gulla, P.; Tristaino, B.; Giordano, P. (Istituto di Clinica Chirurgica e Terapia Chirurgica, Universita di Perugia, Perugia, Italy). *Acta Chir. Ital.* 31(3):357-365; 1975.

Biopsy samples from five patients with chronic pancreatitis were examined by electron microscopy to investigate the existence of an autoimmune factor in the pathogenesis of chronic pancreatitis. The walls of the involved capillaries showed severe alteration of the endothelium and a disrupted structure, very similar to their appearance after administration of ferritin. Extensive lymphocytic infiltration, and alterations in the acinus cells (increase in lipids, vesicles, altered membrane, and mitochondria) and endothelial cell walls support the hypothesis of serum antibody movement. An autoimmune response reacting with a chronic inflammation is suggested by these observations.

LIVER AND BILIARY TRACT

5070 BEHAVIOR OF THE PORTAL VEIN SYSTEM IN MAN AFTER LAPAROTOMY. (Eng.) Eisele, R.; Dissmann, W., Kotter, D.; Nasseri, M.; Thimme, W. (Klinikum Charlottenburg, Berlin, W. Germany). *Surg. Gynecol. Obstet.* 141(6):870-874; 1975.

The behavior of the portal vein system following laparotomy was examined in 41 patients with stomach or colon disease. Before the peritoneum was closed, a catheter was placed in the portal vessel. Portal venous pressure was measured at intervals up to the ninth day, and oxygen and carbon dioxide pressures were measured in portal and venous blood. The arterial oxygen pressure ranged from 70.1 to 67.0 mm Hg, and that of the portal vein ranged from 49.9 to 44.4 mm Hg. The mean values for calculated oxygen content were 1.95, 2.28, 2.08, and 1.58 volume-percent on days 1, 2, 3-4, and 7-9, resp. In all patients, the portal venous pressure increased significantly, and with one exception, was greater than the increase in the arterial system, resulting in a significant ($p<0.01$) drop from 6.9 to 4.8 mm Hg in the portal-central pressure gradient. Cardiac output (measured in 10 patients) increased significantly (range, 6.4 to 8.51 l/min), while the average total arteriovenous oxygen difference decreased from 4.7 to 3.3 volume-percent ($p<0.05$). It is concluded that laparotomy does not influence portal venous pressure or the portal-central venous pressure gradient.

5071 A STUDY OF KINETIC PARAMETERS FOR THE USE OF SERUM ORNITHINE CARBAMOYLTRANSFERASE AS AN INDEX OF LIVER DAMAGE. (Eng.) Drotman, R. B. (Procter and Gamble Co., Ivorydale Technical Center, 5299 Spring Grove Ave., Cincinnati, OH 45217). *Food Cosmet. Toxicol.* 13(6):649-651; 1975.

A simple radiometric assay for serum ornithine carbamoyltransferase (OCT) is described, and the results of studies in which this assay was used to measure OCT activity in normal and CCl_4-treated Cox CD rats are presented. $^{14}CO_2$ released from [^{14}C-ureido]-L-citrulline (0.0227 μCi/μmol, 10 μmol/ml) into the incubation medium by arsenolysis (0.1 M sodium arsenate, pH 6.7) was used as a measure of enzyme activity. The $^{14}CO_2$ was trapped in 1.5 M-NaOH and measured directly by liquid scintillation spectrometry. Serum OCT was stable for at least 2 weeks when stored frozen. Linear relations were observed between $^{14}CO_2$ formation and the time of incubation, and between $^{14}CO_2$ formation and enzyme concentration. When the serum was dialyzed, ornithine and phosphate were not present in large enough concentrations to inhibit the arsenolysis of citrulline (1.6 μmol $^{14}CO_2$/0.4 ml undialyzed serum, 1.3 μmol following dialysis). When rats were injected i.p. with graded doses of CCl_4 (0.0, 37.5, 75.0, 150.0, and 300.0 μl/kg), there was a progressive increase in OCT activity (104, 650, 1,478, 11,275, and 33,308 disintegrations per min/0.4 ml serum or 4, 26, 59, 360, and 1350 μmol/24 hr/l serum for the respective doses of CCl_4). Therefore, the measurement of serum OCT activity is a sensitive index of liver damage and may be of practical use in the toxicology laboratory.

5072 THE SERUM PREALBUMIN SIGNIFICANCE IN THE DIFFERENTIAL DIAGNOSIS OF LIVER DISEASES. (Ger.) Groza, S. (Medizinische Fakultat der Universitat Beograd, Bulevar Revolucije 207/Ill, Belgrade, Yugoslavia). *Med. Klin.* 71(9):378-379; 1976.

Serum prealbumin levels were measured by the Mancini method in 20 healthy subjects, 30 patients with acute hepatitis, 24 patients with chronic hepatitis, and 11 patients with cirrhosis of the liver. The serum prealbumin content averaged 47.4 mg% in the controls, 14.0% in patients with liver cirrhosis, 11.6% in patients with acute viral hepatitis, 33.3% in patients with chronic aggressive hepatitis, and 70.8% in patients with chronic persistent hepatitis. It appears that serum prealbumin determinations may be of value in differentiating chronic persistent hepatitis from chronic aggressive hepatitis. The prealbumin determination does not seem useful for differentiating chronic aggressive hepatitis from cirrhosis of the liver.

5073 PROLYL HYDROXYLASE ACTIVITY IN NORMAL AND DISEASED HUMAN LIVER. (Eng.) Fuller, G. C.; Nolan, J. C.; Fink, S.; Rodil, J. V. (Coll. Pharmacy, Univ. Rhode Island, Kingston, RI 02881). *Proc. Soc. Exp. Biol. Med.* 151(1):61-64; 1976.

The level of prolyl hydroxylase activity in normal and diseased human liver was examined in liver biopsies from 10 adult men. The specimens were examined histopathologically. Prolyl hydroxylase activity was measured in whole homogenates using a method based on the stoichiometric formation of ^{3}H water and ^{3}H-hydroxyproline, when a substrate consisting of a polypeptide with 4-^{3}H-proline was incubated with the enzyme and cofactors. The values obtained could be classed into three populations representing high, low, and intermediate enzyme levels. These corresponded to clinical groupings of active aggressive fibrosis, and normal and active liver disease, resp. The data from this and other studies indicate that this procedure provides a rapid and convenient means of estimating the extent of active fibrogenesis. A ninefold increase in prolyl hydroxylase was observed in patients with aggressive alcoholic hepatitis with only early minimal histopathological evidence of existing fibrosis. Since this technique can be used to predict the progression to cirrhosis in patients with chronic liver disease, and can be done with rapidity, it could be a valuable diagnostic tool.

5074 OSTEOPATHIES AND CALCIUM RESORPTION IN CHRONIC LIVER DISEASES. (Ger.) Gossmann, H. H.; Schaumloffel, E.; Miller, B.; Martini, G. A. (Kreiskrankenhauses, 59 Siegen, Kohlbettstrasse 15, Marburg, W. Germany). *Z. Gastroenterol.* 13(6): 594-598; 1975.

Disturbances in calcium resorption, and their relation to osteoporosis in patients with chronic liver disease, was studied in 16 patients with cirrhosis and in 2 patients with chronic hepatitis. Seven patients had radiologically and histologically proven osteoporosis, and one patient had osteoporomalacia. Calcium-45 (1-3 µCi, p.o.) was administered in 250 ml of buttermilk (about 200 mg calcium); 1 hr later, calcium-47 (6-8 µCi, i.v.) was administered to determine the endogenous excretion rate. The calcium resorption rate was calculated from the excreted calcium-45 activity as a percentage of the administered dosage. Total resorption was evaluated from the calcium resorption rate and the endogenous secreted calcium-47 activity. No reduction in the calcium resorption was observed in patients with liver cirrhosis and chronic hepatitis. The osteoporosis accompanying chronic liver diseases is most probably due to lack of motor activity, muscular atrophy, chronic pancreatitis, alcoholism, and low calcium diet, rather than to reduced calcium resorption. Osteomalacia is a consequence of prolonged cholestasis. Vitamin D is indicated in osteomalacia. The results of this study show no decrease in calcium resorption in patients with cirrhosis of the liver and chronic hepatitis; vitamin D therapy is not indicated.

5075 AN ATTEMPT AT STATISTICAL CORRELATION BETWEEN INTRA-HEPATIC IMMUNOCYTES AND Ig-LEVELS IN LIVER DISEASES. (Fre.) Gardais, J.; Hurez, D. (Centre Hospitalier Regional, 49036 Angers Cedex, France). *Pathol. Biol. (Paris)* 23(9):683-689; 1975.

Needle biopsies were performed on 71 patients with various hepatic diseases (24 with steatosis, 37 with cirrhosis, and 10 with hepatitis). The immunocytes reacting with specific conjugated antisera anti-immunoglobulin G (IgG), -IgA, and -IgM were counted. Immunoelectrophoresis counts were above normal in steatosis, 27 cirrhosis, and in 9 hepatitis patients; a monoclonal IgM was found in 1 patient with hepatitis. Regardless of the illness, the average number of immunocytes reacting with the anti-IgA specific antiserum was always greater than that corresponding to the anti-IgG and anti-IgM antisera. It was impossible to statistically correlate immunocytochemical data with Ig levels. It is suggested that the increase in immunoglobulins is related to an increased, rather than a decreased, catabolism. The infiltration of the hepatic parenchyma and the portal spaces by immunocytes may be reponsible for the increased count of serum immunoglobulins.

5076 LYMPH VESSEL SYSTEM AND LIVER: FUNCTIONAL AND PATHOPHYSIOLOGICAL RELATIONSHIP. (Ger.) Foldi, M. (Fa. Schaper & Bruemmer, D-3320 Saltzgitter 61, Bahnhofstr. 35, W. Germany). *Leber Magen Darm* 4(6):274-279; 1974.

In almost all hepatopathies, the lymphatic system is involved. The protein concentration of hepatic lymph is 80-95% that of blood plasma; 70-100% of all circulating plasma proteins are transported by the hepatic lymph vessels to the blood circulation each day. Lymph formation in the liver probably occurs in the sinusoids, but also in biliary and gallbladder capillaries. Ascites in hepatic cirrhosis causes increased lymphatic flow and intralymphatic pressure, resulting in drainage into the peritoneal cavity. Determination of the protein concentration in the ascitic fluid and the lymph enables evaluation of the state of the liver cirrhosis. Occlusion of the lymphatic vessels or insufficient drainage results in damage to the liver cell and the reticuloendothelial system. An accurate definition of the role of the lymphatic system is an important prerequisite for the evaluation of therapeutic treatment of liver diseases.

LIBRARY U. [illegible]

5077 SERUM GASTRIN LEVELS FOR VARIOUS LIVER DISEASES. (Jpn.) Takaoka, Y.; Katayama, A. (Osaka Prefectural Hosp., Osaka, Japan). *Radioisotopes* 24(2):56-58; 1975.

The serum gastrin level in patients with various liver diseases was measured using a gastrin kit, and compared with that in normal healthy controls. Seventeen patients had acute hepatitis, 40 chronic hepatitis, 47 cirrhosis, and 8 hepatoma. The gastrin level in the healthy patients in early morning before breakfast was 107.3 ± 33.4 pg/ml. There was no difference in the serum gastrin level of the chronic hepatitis and cirrhosis patients compared to controls. The average serum gastrin level of the acute hepatitis patients was 86.4 ± 31.1 pg/ml, and that of the hepatoma patients was 145.3 ± 117.5 pg/ml. The effect of Honig beef bouillon cubes on changes in the serum gastrin level was examined in 13 patients, as was the time required to reach the maximum serum gastrin level after its administration. The patients reached a peak gastrin level after 10 min and after 60 min, the level returned to that of the empty stomach. Two patients with chronic hepatitis showed extremely high serum gastrin levels after 10 min (350 and 380 pg/ml).

5078 TREATMENT OF VARIOUS LIVER DISEASES WITH (+)-CYANIDANOL-3, A NEW HEPATO-PROTECTIVE SUBSTANCE. (Eng.) Martinez Lopez, J. M.; Sanchez de la Cuesta, F.; Calvo Fernandez, R. Garrida Toro, A.; Merchante Cobos, J. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* Bertelli, A., ed. (New York: S. Karger): pp. 201-206; 1975.

A new hepato-protective drug, (+)-cyanidanol-3 (C-3), was clinically evaluated in 40 patients with liver disease, either of alcoholic or iatrogenic origin, or acute hepatitis of heterogeneous origin. Thirty-eight patients received 6 tablets per day, and two patients whose disease was not so severe received 3 tablets per day. The biochemical parameters examined included urobilin, biliary pigments and salts, urobilinogen, sedimentation rate, total bilirubinemia, prothrombin time, transaminase, phosphatases, lactate dehydrogenases, serum lability, and when needed for diagnosis, liver biopsy and the BSP test. Of the 12 patients with alcohol-induced liver disease, 2 showed very good results, 7 showed good results, 2 showed fair results, and 1 did not respond. The majority of symtoms in these cases disappeared, but there was a persistence of anorexia, arthromyalgia, and discrete hepatomegaly. Bilirubinemia, transaminases, and alkaline phosphatases returned to normal levels. Of the 14 patients in the iatrogenic group, 3 showed a very good response, 10 showed a good response, and 1 showed a fair response. Flatulence, meteorism, and constipation persisted at the end of treatment. Patients with heterogeneous liver disease showed 2 very good responses, 9 good responses, 1 fair response, and 1 lack of response. At the end of treatment, the most persistent clinical symptoms were lassitude, migrane, and arthromyalgia. One response was unaccounted for in the tables.

5079 HEPATIC EFFECTS OF ORAL CONTRACEPTIVES. (Fre.) Emond, M.; Beaudoin, M. (Departement de medecine, hopital Notre-Dame, 1560 est, rue Sherbrooke, Montreal H2L 4K8, Canada). *Union Med. Can.* 104(10):1539-1541; 1975.

Hepatic effects of oral contraceptives and contraindications to their use are reviewed. Outside of Chili and Sweden, cholestasis due to oral contraceptives is very rare. When it does occur, the jaundice usually disappears without a trace within 2 weeks of cessation of the drug. Oral contraceptives are contraindicated if the woman has had a gravidic cholestasis. Cases of chronic hepatic disease (chronic active hepatitis, primary biliary cirrhosis) and familial hyperbilirubinemia (Dubin-Johnson and Gilbert syndromes) are relative contraindicators to oral contraceptives. Hepatic tests do not have to be systematically checked in normal women taking oral contraceptives.

5080 LIVER TRANSPLANTATION FOR BUDD-CHIARI SYNDROME. (Eng.) Putnam, C. W.; Porter, K. A.; Weil, R., III; Reid, H. A. S.; Starzl, T. E. (Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80220). *JAMA* 236(10):1142-1143; 1976.

The first use of liver replacement for the treatment of the Budd-Chiari syndrome is reported. Ten months before the operation, the patient, a 22-yr-old woman, experienced right upper quadrant pain, nausea, vomiting, and abdominal distention. There was progressive enlargement of the liver and spleen, the development of spider angiomas, increasing ascites, peripheral edema, and episodes of hepatic encephalopathy. The diagnosis was confirmed by liver biopsy and by a venacavogram. Narrowing of the inferior vena cava and occlusion of the hepatic veins by organized and recanalized thrombus were seen. Two months before transplant, the patient's renal function began to deteriorate. The donor (a 21-yr-old woman) and recipient had mismatches of all four antigens of the histocompatibility antigen A and B loci. The removal of the diseased liver was made difficult by dense fibrosis around the suprahepatic and retrohepatic inferior vena cava, but the hepatectomy was facilitated by a retrograde technique that allowed the dissection of the suprahepatic vena cava to be postponed until just before the removal of the specimen. Postoperatively, the patient received azathioprine, prednisone, and a 3-week course of heterologous antilymphocyte globulin. Liver rejection did not occur, and renal function was restored within 3 weeks. Two episodes of fever associated with elevated liver enzymes were thought to represent cholangitis and were easily controlled with antibiotics. The patient has normal liver function 16 months after the transplant.

5081 EARLY DIAGNOSIS OF PRIMARY LIVER CARCINOMA. (Ger.) Weiss, W.; Dittrich, H.; Baumgartner, G.; Blazek, F.; Eder, G.; Hanak, H.; Hentschel, E.; Kahn, P.; Mastnak, C.; Urbanek, A.

(1. Medizinische Abteilung, Hanusch-Krankenhaus, Heinrich-Collin-Strasse 30, A-1140 Vienna, Austria). *Wien. Med. Wochenschr.* 126(1/3):16-22; 1976.

The incidence and diagnosis, as well as a diagnostic program, of primary carcinoma of the liver (PCL) in an Austrian hospital were evaluated. Forty cases of PCL were found in 1973-74 among 560 gastrointestinal patients. A high-risk group consisted of patients with decompensated liver cirrhosis, suspicion of occult neoplasms, or liver scintigrams showing parenchymal defects. Diagnostic criteria were medical history, clinical symptoms, laboratory tests, especially α-fetoprotein, liver scintigraphy, and angiography. α-Fetoprotein was present in the plasma of 88-90% of patients with hepatocellular carcinoma. Thirty-four of the 40 patients with PCL died. The diagnosis was confirmed by autopsy in 30 cases; in the remaining cases, autopsy was not performed. This test is prefered to more sensitive tests, which have the disadvantage of a higher rate of wrong positive results. Laparoscopic biopsy diagnosis is rejected as a routine procedure, since it proves right in only 40-60% of the cases.

5082 A CASE OF PRIMARY UNDIFFERENTIATED SARCOMA OF THE LIVER: DIAGNOSED BY PERITONEOSCOPY AND GUIDED BIOPSY.

(Eng.) Esposito, R.; Pollavini, G.; de Lalla, F. (Univ. Milan Medical Sch., Via Livigno 3, I-20158 Milan, Italy). *Endoscopy* 8(2):108-110; 1976.

A rare case of primary undifferentiated liver sarcoma is reported. The patient, a 36-yr-old man, presented with jaundice, right upper quadrant pain, hepatomegaly, and a nontender, round mass in the abdomen. Peritoneoscopy and needle biopsy were performed. The biopsy specimen revealed a marked variation in cellularity, with cells varying from spindle to polyhedral shape, and some foreign body giant cells. There was a uniform distribution of reticulum fibers characteristic of a sarcoma, and the histological diagnosis was undifferentiated liver sarcoma. The patient died 2 months later, and the diagnosis was confirmed at autopsy.

5083 FOCAL NODULAR HYPERPLASIA OF THE LIVER, BENIGN HEPATOMAS, ORAL CONTRACEPTIVES AND OTHER DRUGS AFFECTING THE LIVER.

(Eng.) Grabowski, M.; Stenram, U.; Bergqvist, A. (Univ. Hosp., Lund, Sweden). *Acta Pathol. Microbiol. Scand.* [A] 83(6):615-622; 1975.

Cases of focal nodular hyperplasia of the liver and benign hepatoma occurring in two Swedish hospitals were examined to establish the association between these lesions and oral contraceptives. Twenty-six cases of focal nodular hyperplasia of the liver and seven benign hepatomas were found in women between 1960 and 1974. Since 1963, the year before oral contraceptives were introduced in Sweden, focal nodular hyperplasia has been diagnosed in eight women in the reproductive period of life, four of whom had taken oral contraceptives. The four diagnoses were established between 1972 and 1974. At most, 25% of Swedish women between the ages of 15 and 44 yr have been on oral contraceptives. Three epileptics and three diabetics were in the group with focal nodular hyperplasia. At least two epileptics had been treated with barbiturates and/or hydantoins. The prevalance of drug-treated epilepsy in Sweden is 0.4-0.5%, and of diabetes about 2%. Drugs provoking an increase of hepatic smooth-surfaced endoplasmic reticulum and proliferation of vascular fibrous tissue in a part of the liver that previously may have been damaged by vascular disturbances or trauma may be involved in the etiology of focal nodular hyperplasia. No relationship between benign hepatomas and drugs was found. The observations support the theory that oral contraceptives are involved in the development of focal nodular hyperplasia of the liver, although the sample is too small for epidemiological and statistical analysis.

5084 REVERSIBILITY OF HEPATIC LESIONS CAUSED BY CHOLELITHIASIS.

(Ger.) Reichmann, J.; Holle, G.; Wohlgemuth, B.; Bienia, M.; Schumann, C. (Kreiskrankenhaus, 74 Altenburg, Leipziger Strasse 5, Leipzig, E. Germany). *Dtsch. Gesundheitswes.* 31(6):267-271; 1976.

To determine the speed of the reversibility of pathological changes in the liver associated with biliary disease, biopsies were performed on 2,325 patients who were operated on for gallstones. Histological examination of the biopsies revealed that liver damage was present in 61.8% of the patients. Diffuse fatty liver was seen in 13.3%, probably due to diabetes mellitus and sensitivity to certain nutritional stimuli, combined with adiposis. In 12.9% of the biopsies, biliary hepatitis and secondary biliary cirrhosis were present, whereas another 12% showed residual cholangitic changes. In all other patients, the pathological changes could be attributed to cholelithiasis. A second biopsy was performed on 159 patients. Complete or very extensive regression occurred in most patients, if no complications or secondary operations interfered with the healing process. Inflammatory changes disappeared fastest and most strikingly within 5-7 months. Hepatitis with toxic parenchymal damage normally reversed within a yr. Marked fatty degeneration of the liver was often present after 1 yr, and even increased in some cases. Since the reversibility and the degree of liver damage depend on the duration and the severity of the cholelithiasis, early treatment of this disease is clearly indicated.

5085 ESTROGEN THERAPY INTRAHEPATIC CHOLESTASIS: CHARACTERISTICS OF HIGH-RISK PATIENTS.

(Eng.) Neilan, L. (Georgetown Univ. Sch. Medicine, Washington, DC). *J. Am. Med. Wom. Assoc.* 31(3):97-108; 1976.

To predict those women in whom estrogen therapy

LIBRARY

could result in intrahepatic cholestasis, an attempt was made to determine risk factors from clinical reports of jaundice or pruritus and biochemical analysis of bile of women on estrogen therapy. Estrogen causes cholestasis primarily by reducing bile salt formation and bile flow. It also inhibits bilirubin entry into the hepatocyte and its subsequent conjugation with glucuronic acid. Estrogen alters serum lipoproteins, labilizes lysosomes, and increases cholesterol, which could change the nature of the cell membrane at the canaliculi. Most canaliculi show dilation, reduction in number and height of microvilli, and a few whorl bodies. Liver biopsy can provide definitive evidence for intrahepatic cholestasis. Most patients become jaundiced on estrogen therapy in the first 2 months. Hypertriglyceridemia is commonly seen in women with cholestatic jaundice. Bile stasis is suspected as a cause of pancreatitis by reflux into the common bile duct. Serum alkaline phosphatase and serum copper elevations are the most indicative test for cholestasis evaluation. Radioimmunoassay of bile salts may prove useful in detecting impaired liver function from estrogen therapy before the clinical appearance of jaundice or pruritus.

5086 INTRAHEPATIC CHOLESTASIS WITH PARENTERAL ALIMENTATION. (Eng.) Rodgers, B. M.; Hollenbeck, J. I.; Donnelly, W. H.; Talbert, J. L. (J. Hillis Miller Health Center, Gainesville, FL). 32610). *Am. J. Surg.* 131(2):149-155; 1976.

An attempt was made to define the clinicopathologic correlates of intrahepatic cholestasis resulting from parenteral alimentation in 11 neonates. Six of the neonates weighed less than 2.0 kg at birth, and five of these were estimated to be 30 weeks or less gestational age. The infants were alimented by standard techniques with a 20% glucose solution containing 2.5 g/100 ml protein (except one case, which received 3.25 g/100 ml protein). Alimentation was carried out for an average of 75 days (range, 26-236 days) during which it was supplemented with oral or gastrostomy feedings. All of the neonates had moderate to severe elevation of serum bilirubin at some point during the i.v. alimentation (IVA; range, 3.6-23.1 mg/100 ml). Serum bilirubin levels peaked on an average of 29 days after the onset of IVA (range, 4-47 days). There were significant liver enzyme abnormalities in seven infants; SGOT ranged between 115 and 2,530 U. Alkaline phosphatase (measured in 4 patients) ranged between 58 and 100 King-Armstrong U. Discontinuation of IVA resulted in a return to normal of serum bilirubin and liver function. In the two infants that survived, liver function studies have remained normal for 2.5 yr. While the cause of cholestasis associated with parenteral alimentation is unknown, this study indicates that it may be associated with prematurity and with sepsis. The authors propose that careful monitoring of liver function parameters be carried out in all infants on total or partial parenteral alimentation, and especially on premature infants. Persistent elevations of serum bilirubin and SGOT indicate that IVA should be discontinued, if at all feasible.

5087 PHENOBARBITAL AND CHOLESTYRAMINE IN RECURRENT INTRAHEPATIC CHOLESTASIS. (Hun.) Laszlo, B.; Mehesfalvi, E. (Fovarosi Laszlo Korhaz, Budapest, Hungary). *Orv. Hetil.* 116(23):1343-1345; 1975.

Successful phenobarbital and cholestyramine treatment of two patients with recurrent intrahepatic cholestasis is reported. Phenobarbital therapy (135 mg/day, p.o.), initiated after 30 days of refractory jaundice (5th crisis) in a 23-yr-old man, caused only partial and temporary improvement. Similar improvement was achieved with cholestyramine (12 g/day), after 30 days of phenobarbital treatment. Phenobarbital therapy (135 mg/day), combined with the ongoing cholestyramine therapy on the 90th day of the jaundice, resulted in rapid normalization (cessation of pruritus, normocholic feces, and a drop in the serum bilirubin level and in the alkaline phosphatase activity). The patient was discharged symptom-free 25 days after the initiation of the combined therapy. A 17-yr-old man, presenting with familial recurrent intrahepatic cholestasis, had had four icteric crises lasting 137, 65, 58, and 67 days, and he received a combination of phenobarbital (100 mg/day) and cholestyramine (12 g/day) during his fifth crisis. Rapid normalization occurred. He was discharged symptom-free 24 days after the initiation of the combined therapy. The duration of the fifth crisis was only 29 days. These two cases suggest a possible synergism between phenobarbital and cholestyramine; however, additional evidence is required to confirm that the rapid regression of symptoms of recurrent intrahepatic cholestasis is due to the therapeutic effectiveness of the phenobarbital-cholestyramine combination.

5088 FACTOR VII LEVELS AS A GUIDE TO PROGNOSIS IN FULMINANT HEPATIC FAILURE. (Eng.) Gazzard, B. G.; Henderson, J. M.; Williams, R. (King's Coll. Hosp. Medical Sch., London, England). *Gut* 17 (7):489-491; 1976.

Because of a recent suggestion that reductions in levels of clotting factor VII to less than 9% of normal indicate a poor prognosis in patients with grade IV hepatic encephalopathy, clotting factor VII was measured in 12 patients in grade IV hepatic coma for up to 36 hr. Five patients regained consciousness after receiving an average of three charcoal hemoperfusions. Only four of these patients survived, the fifth died 2 weeks later of an infection. Factor VII levels at the time of admission were below 9% of normal in four of the five patients who regained consciousness. Subsequent levels in these four patients increased to 9% or above. In six of the seven fatal cases, the hepatocyte volume fraction was less than 20%; these patients died of a complication of acute hepatic failure. In three fatal cases, the factor VII levels on admission were greater than 9% of normal, but fell below 9% in two of these three patients. The results indicate that the initial factor VII levels were not useful in predicting the prognosis of patients in grade IV hepatic coma. Serial determinations were a more useful predictor; the levels fell in those who died, whereas a rise was observed in those who recovered. It appears unlikely that any single test will be completely reliable in determining the prognosis of this condition.

5089 STUDIES IN PORPHYRIA. V. DRUG OXIDATION RATES IN HEREDITARY HEPATIC PORPHYRIA.

(Eng.) Anderson, K. E.; Alvares, A. P.; Sassa, S.; Kappas, A. (Rockefeller Univ., New York, NY). *Clin. Pharmacol. Ther.* 19(1):47-54; 1976.

To determine if there is a diminshed heme synthesis in hereditary hepatic porphyria, cytochrome P-450 function was assessed in 10 patients with the disease in remission and in seven asymptomatic genetic carriers. The mean plasma half-life of antipyrine was prolonged (21.69 ± 1.92 hr) in the 10 patients with disease, 8 of whom had acute intermittent porphyria (AIP) confirmed by decreased erythrocyte uroporphyrinogen-1-synthetase (URO-S) activities, and 2 of whom had mixed hepatic porphyria, in comparison to the mean of 20 normal control subjects (12.65 ± 0.86 hr, $p<0.01$). Antipyrine half-life was especially prolonged in patients with a history of more severe symptoms, but there was no correlation with the degree of elevation in urinary excretion of the porphyrin precursors δ-aminolevulinic acid (ALA) and porphobilinogen (PBG). The elimination rates of antipyrine from plasma were normal in the seven carriers of the AIP gene defect who had normal urinary ALA and PBG levels. The phenylbutazone half-life was normal in the 10 porphyric patients. The results demonstrate that the cytochrome P-450-dependent enzyme system for oxidizing antipyrine, but not that for phenylbutazone, is impaired in some AIP individuals in whom the gene defect for the disorder is clinically expressed, and that this impairment may be related to the severity of the disease. The partial decrease in URO-S activity characteristic of AIP does not result in a profound or generalized decrease in hepatic cytochrome P-450 function, even when there is sufficient derangement in the hepatic heme biosynthetic pathway to lead to excessive excretion of chemical intermediates in the pathway.

5090 THE HUMAN HEPATOCYTE IN STEATOSIS: AN ULTRASTRUCTURAL STUDY. THE RECONSTRUCTIVE EFFECT OF PHOSPHATIDYLCHOLINES WITH POLYENE TYPE FATTY ACIDS.

(Fre.) Alliet, J.; Comlan, G.; Gourdier, D. (Laboratoire d'Histologie-Embryologie, UER de Medecine, Caen, France). *Ouest Med.* 29(2): 85-104; 1976.

Ninety-four children (18 months-6 yr) in a state of severe denutrition (kwashiorkor) were treated either with lecithins and unsaturated fatty acids (total of 18 days), first by perfusion then p.o. when the state of consciousness of the patient allowed it, or with standard hyperprotein treatment, or with both. Biopsies were performed before, during, and after treatment. Hepatic steatosis caused by denutrition was expressed at the level of the hepatocyte by the disruption of cellular ultrastructure. There were zones of densification and rupture on the hepatocytic membrane. The nucleus contained either a hypertrophied nucleolus or two to three nucleoli. The nuclear membrane was dilated, due to an excess of lipids, and accompanied by a loss of ribosomes on the membrane and degranulation of the rough endoplasmic reticulum. There were also mitochondrial anomalies (loss of crests) and hypertrophy of the Golgi apparatus. Lecithins with polyene fatty acids restored membrane structure most rapidly; membrane enzymatic activity resumed. The almost complete disappearance of the intrahepatocytic excess of lipids was indicative of a recovered hepatocellular morphology. Three typical case histories are presented.

5091 REYE'S SYNDROME IN AN ADULT.

(Eng.) Morse, R. S.; Holmes, A. W.; Levin, S. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *Am. J. Dig. Dis.* 20(12):1184-1190; 1975.

The case of a 25-yr-old man with Reye's syndrome is reported. The usual prodromal symptoms of an upper respiratory infection followed by slight improvement followed by the development of vomiting, encephalopathy, mental confusion, and hepatic dysfunction were seen. During his recovery, the patient manifested clinical jaundice; the cause was unclear, although he had received one injection of thorazine. Histological examination of a liver biopsy specimen revealed fatty vacuolization of the hepatocytes with minimal mononuclear inflammatory infiltrate, and electron microscopy revealed an extensive fatty infiltrate, distorted mitochondria, and deglycogenation. The serum influenza B titer was elevated (1:128), although this did not change during the observation period. Cytomegalovirus (≤1:8) was isolated in the urine, but no other manifestation of cytomegalovirus infection was noted. The serum amino acid elevations in this patient were more generalized than those in other reported cases of Reye's syndrome. The patient never manifested depressed glucose levels in the blood or in a single-determination cerebrospinal fluid. The patient was treated with p.o. neomycin, catharsis, and protein restriction. He improved rapidly and had no residual evidence of liver or central nervous system damage. The fact that Reye's syndrome has now been diagnosed in an adult is stressed.

5092 AN OUTBREAK OF HEPATIC VENO-OCCLUSIVE DISEASE IN NORTH-WESTERN AFGHANISTAN.

(Eng.) Mohabbat, O.; Younos, M. S.; Merzad, A. A.; Srivastava, R. N.; Sediq, G. G.; Aram, G. N. (Inst. Pathology, Univ. Kabul, Kabul, Afghanistan). *Lancet* 2 (7980):269-271; 1976.

An outbreak of veno-occlusive disease (VOD) of the liver caused by consumption of *Heliotropium* seeds is reported. Approximately 1.5 yr after a 2-yr period of severe drought in north-western Afghanistan, 22.6% of a population of 7,200 developed evidence of liver disease. There were 1,034 males and 598 females, 46% of them under 14 yr of age. Early symptoms included

LIBRARY U. C.

anorexia, lassitude, and weight loss; severe abdominal distension and emaciation developed within several weeks. Jaundice and fever were rare, and in about 10% of patients, the liver was not palpable. The disease was usually fatal within 3-9 months. In 21 hospitalized patients who had the disease for 1-6 months, the mean serum albumin, serum globulin, SGPT, and alkaline phosphatase levels were 3.2 g/dl, 3.3 g/dl, 46 U, and 14.0 King-Armstrong U, resp. Clinical improvement was observed in 18 cases after 3-9 months of supportive hospital treatment; the 3 remaining patients, who had more advanced disease, died. Five autopsy specimens and 16 percutaneous liver biopsy specimens were examined. Microscopically, there was striking centrilobular congestion with extreme hemorrhagic necrosis of the parenchymal cells, and the central veins were often unrecognizable. These abnormalities had almost disappeared in the liver biopsy specimens from three patients who had complete clinical recovery after 9 months in the hospital. Contamination of flour with *Heliotropium* seeds was the cause of the outbreak. The alkaloid content (primarily heliotrine and lasiocarpine) in samples of wheat flour varied from 0.500% to 0.186%, and traces of alkaloid were detected in urine specimens from five patients.

5093 HEPATIC VENO-OCCLUSIVE DISEASE ORIGINATING IN ECUADOR. (Eng.) Lyford, C. L.; Vergara, G. G.; Moeller, D. D. (167 South Conwell, Casper, WY 82601). *Gastroenterology* 70(1):105-108; 1976.

A case of hepatic veno-occlusive disease manifested by massive ascites is described. A 35-yr-old woman had consumed an herbal tea containing a Crotalaria plant species for 6 months prior to evaluation. For 6 weeks she had consumed 2 liters, and subsequently 1 liter daily of the brew. She developed marked ascites, prominent superficial abdominal veins, and hepatomegaly. The inferior vena cava and hepatic veins were patent by angiography. Liver biopsy showed histological changes typical of hepatic veno-occlusive disease, consisting of centrilobular congestion and sublobular hepatic vein obstruction. Complete clinical, biochemical, and histological recovery was documented 1 yr after ingestion of the brew was discontinued. This is the first case known to be reported from Ecuador and the first to be diagnosed in the United States.

5094 AN EPIDEMIC OF VENO-OCCLUSIVE DISEASE OF LIVER IN CENTRAL INDIA. (Eng.) Tandon, B. N.; Tandon, H. D.; Tandon, R. K.; Narndranathan, M.; Joshi, Y. K. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Lancet* 2 (7980):271-272; 1976.

A second outbreak of veno-occlusive disease occurring in the Sarguja district of India in November-December 1975 is reported. Of 67 reported cases, 28 were fatal. Thirty-three patients were examined. Pain in the epigastrium followed by rapid abdominal distension was the most common presenting symptom. All but one patient had ascites. Three of the 17 patients in whom liver function was tested had hyperbilirubinemia, and 13 had slightly raised serum alkaline phosphatase values. All 17 patients were negative for hepatitis B surface antigen. Pathological examination of biopsy and autopsy specimens revealed large areas of centrilobular hemorrhagic necrosis. In all autopsy liver specimens, the central and sublobular veins showed varying degrees of occlusion with edematous collagenous connective tissue. This outbreak was probably caused by consumption of a cereal heavily contaminated with seeds of the *Crotalaria* species, which contain alkaloids of the pyrrolizidine group.

5095 FAMILIAL HEPATIC VENOOCCLUSIVE DISEASE WITH PROBABLE IMMUNE DEFICIENCY. (Eng.) Mellis, C.; Bale, P. M. (Royal Alexandra Hosp. Children, Camperdown, 2050, New South Wales, Australia). *J. Pediatr.* 88(2):236-242; 1976.

The cases of five infants with venoocclusive disease that appeared not to be associated with dietary or other extrinsic causes are presented. Hypogammaglobulinemia was severe in three infants and borderline in another. In one case, the failure of development of lymphoid germinal centers indicated immune disease. *Pneumocystis carinii* pneumonia occurred in four infants. It seemed unlikely that this was secondary to malnutrition, as there was no alveolar plasma cell reaction, and only one infant had wasted limbs. Numerous Hassall's corpuscles were found in the thymus, also suggesting a humoral immunity deficiency. Whether hypogammaglobulinemia was related to venoocclusive disease of the liver or was merely coincidental to it in these cases could not be determined. Microcephaly, multiple small cerebral softenings, yellow regenerative nodules, and left atrial endocardial fibrosis were also observed. The authors suggest that congenital immunodeficiency may have caused the venoocclusive disease in these cases.

5096 HEPATOLENTICULAR DEGENERATION: BIOCHEMICAL AND THERAPEUTIC CONSIDERATIONS. (Ita.) Mancinella, A.; Bartolucci, E. (Ospedale Civile Carretta, Montebelluna, Italy). *Clin. Ter.* 76(6):567-576; 1976.

The histological and clinical aspects of Wilson's disease are reviewed. It is characterized histologically by an abnormal deposit of copper in various tissues and clinically by extrapyramidal symptoms, psychic disorders, and cirrhosis. Treatment is based on the prolonged administration of drugs that block the intestinal absorption of copper, such as chelating agents (potassium sulfide, EDTA, D-penicillamine), cortisones (prednisone, 6-methylprednisolone), and antiparkinson drugs (L-dopa and amantadine combined with penicillamine). Copper-deficient diets are also employed as therapy.

5097 THE EFFECT OF LONG-TERM TREATMENT WITH d-PENICILLAMINE ON THE HUMORAL IMMUNE RESPONSE IN PATIENTS WITH WILSON'S DISEASE. (Eng.) Czlonkowska, A. (Inst. Psychoneurology, Warszawa, Poland). *Mater. Med. Pol.* 8(1):48-50; 1976.

The effects of long-term treatment with d-penicillamine on the synthesis of immunoglobulins (Ig) and antibodies to bacterial antigens were investigated in 21 patients with Wilson's disease. One group of 8 patients had been receiving d-penicillamine for 2 yr or more; the other 13 patients did not receive the drug. A radial immunodiffusion method was used to measure IgG, IgA, and IgM. Antibodies to common antigen (C.A.) of Enterobacteriaceae and O antigen of S-typhi were determined by a passive hemagglutination method. Long-term treatment with d-penicillamine resulted in a decreased serum IgA (111.31 ± 113.43 IU/ml). Patients receiving d-penicillamine had lower IgG and IgM levels than patients not receiving the drug ($p<0.05$). Long-term treatment with d-penicillamine also reduced the level of antibodies to C.A. and to antigen O of S-typhi. Thus, a fall occurs in the immune response of the humoral type. Penicillamine exerts a direct influence on immunocompetent cells, which inhibits the synthesis of antibodies.

5098 PORTAL CIRCULATION AFTER LONG-TERM D-PENICILLAMINE TREATMENT FOR LESIONS OF THE HEPATIC PARENCHYMA IN WILSON'S DISEASE. (Ger.) Seidlova, V.; Kuba, J. (Medizinische Fakultat, Palacky-Universitat, Olomouc, I. P. Pavlova 6, Czechoslovakia). *Dtsch. Z. Verdau. Stoffwechselkr.* 35(1):17-23; 1975.

Splenoportoscintography was performed on five patients with Wilson's disease to study portal circulation and the possible development of portal hypertension resulting from changes in liver cell tissue associated with this disease. The patients, aged 19-28 yr, had been treated with D-penicillamine (1 g/day) for an average of 10 yr. Cirrhosis of the liver was present in all cases. After D-penicillamine treatment, all patients improved clinically and biochemically. Splenomegaly subsided only temporarily. Esophageal varices were found in one patient at the onset of treatment and were present in three patients after 10 yr. Splenoportoscintography showed marked pathological changes in the portal circulation, indicating portosystemic shunts, in four of the five patients; in two patients, unusual intrahepatic shunts were observed. In one patient, a spontaneous anastomosis, similar to a mesocaval shunt, was present. Electroencephalographic examination revealed possible portosystemic encephalopathy in two cases. The authors conclude that the possibility of developing portal hypertension is very real in patients with Wilson's disease, despite the obvious improvement following treatment with D-penicillamine.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

5129 BROMOSULFOPHTHALEIN EXCRETION AND HYPERBILIRUBINEMIA IN GILBERT'S DISEASE. (Ger.) Cartei, G.; Chisesi, T.; Cazzavillian, M.; Barbui, T.; Battista, R.; Dini, E. (Hamatologishe Abteilung, Stadtischen Krankenhauses, Vicenza, Italy). *Dtsch. Z. Verdau. Stoffwechselkr.* 35(4): 169-173; 1975.

The rate of BSP clearance and the relation between the unconjugated serum bilirubin level and the abnormalities in BSP metabolism were studied in 23 unrelated patients with Gilbert's disease. BSP (5 mg/kg, i.v.) was administered, and the transfer rates from plasma to liver, from liver to bile, and the return from liver to plasma were determined for a 90-min period. Compared to 50 controls, BSP transfer from plasma to liver was reduced in 95.6% of the patients (mean values 0.0944 ± 0.0026 and 0.1375 ± 0.0024 mg/mg/min, resp.) and for transfer from liver to bile in 91% (mean values 0.0348 ± 0.0017 and 0.0872 ± 0.0067 mg/mg/min, resp.). Transfer from liver to bile was slightly elevated (0.0078 ± 0.0001 compared to 0.0056 ± 0.0008 mg/mg/min). BSP retention after 45 min was elevated in 56% of the patients (mean value 3.59 ± 0.35 mg/mg/min as compared to 1.04 ± 0.19 mg/mg/min for controls). Technical failure of transfer had to be excluded, since transfer rates were irregular in different patients. Since BSP, as well as bilirubin uptake by the liver, are regulated by the Z and Y protein mechanism, a defect in this mechanism could explain the reduced liver BSP uptake. In 86.9% of the patients, two defects in transfer were present, i.e. in uptake by the liver and in transfer to the bile.

5130 THE TITRE OF IgG ANTI-A/B IN THE SERUM OF GROUP O MOTHERS OF INCOMPATIBLE INFANTS WITH EARLY NEONATAL JAUNDICE. (Eng.) Carapella-de Luca, E.; Pacioni, C.; Tonelli, C. (Istituto di Puericultura dell'Universita, Policlinico Umberto I, Roma, Italy). *Vox. Sang.* 30(3):200-203; 1976.

The titer of immunoglobulin G (IgG) anti-A/B was determined in the sera of 80 blood group O mothers, who gave birth at term to A/B incompatible infants. The infants developed early neonatal jaundice with a serum bilirubin level of over 10 mg/100 ml. The titers were determined using a 2-mercaptoethanol test and were compared with the results of the direct antiglobulin test performed on the RBC from the cord blood and the necessity for exchange transfusion. The IgG anti-A/B titers ranged between 1/8 and 1/4,096. In mothers of group A infants, a significant correlation was found between the titer of IgG anti-A and the occurrence of a positive antiglobulin test. The need for an exchange transfusion was not correlated with the IgG anti-A/B titer.

Nonviral Hepatitis and Hepatic Injury

5135 MORPHOLOGY OF DRUG-INDUCED LESIONS OF THE LIVER. (Ger.) Hubner, K. (Senckenbergischen Zentrum d. Pathologie d. Univ., 6000 Frankfurt a. M. 70, Theodor-Stern-Kai 7, W. Germany). *Therapiewoche* 26(5):590-604; 1976.

Drug-induced liver damage constitutes a large portion of all liver diseases. Some drugs always have a toxic effect, whereas others are hepatotoxic only in certain patients. Liver damage can be the result of changes in the liver cell cytoplasm, inflammation, or destruction of the liver cells. Cytoplasmic changes, leading to hyperplasia of the smooth endoplasmic reticulum, are the result of chronic use of, among others, analgesics, barbiturates, or some tuberculostatic drugs. Fatty degeneration of the liver, also caused through cytoplasmic changes and leading to liver failure and death, can occur after large doses of tetracycline. Cortisone therapy can also induce fatty liver. Phenacetin often leads to lipofuscinosis. Anabolic agents, steroids, and many oral contraceptives can cause intrahepatic cholestasis, sometimes associated with liver cell necrosis and inflammatory changes, which may also be seen after the use of chlorpromazine, some antiepileptic, antidepressive, antibiotic, cytostatic, or laxative drugs. Liver disease similar to viral hepatitis is seen after the use of the fluorinated agent halothane and is even more common after repeated exposure. Chronic aggressive hepatitis, sometimes leading to cirrhosis, can be caused by laxative agents containing phenolosatin. The degree of liver cell necrosis caused by tuberculostatic drugs, is dependent on the duration of the medication.

5136 LIVER DAMAGE CAUSED BY LAXATIVES: A CONTRIBUTION TO THE HEPATOTOXICITY OF 4,4'-(2-QUINOLYLMETHYLENE)DIPHENYL-HYDROCHLORIDE. (Ger.) Wiegelmann, W.; Borchard, F.; Irmscher, K. (Medizinische Klinik der Universitat, 4 Dusseldorf, Moorenstr. 5, W. Germany). *Arzneim. Forsch.* 25(6):949-951; 1975.

A case of liver cell damage with intrahepatic cholestasis caused by 4,4'-(2-quinolylmethylene)diphenyl-hydrochloride (CDH) is described. The patient, a 46-yr-old woman, had been using laxatives for years. After six weeks of intermittent use of CDH, colic-like pains developed, and blood chemistry revealed hyperbilirubinemia, elevated GOT, GPT, alkaline phosphatase, and γ-GPT. After renewed exposure to the laxative agent, clinical symptoms appeared after 3-4 hr; biochemical changes were evident 9 hr later. Histologic damage of the bile ducts and scattered liver cell necrosis, plus marked depression of bilirubin secretion, were present in the acute phase of the disease. Antibodies against liver tissue antigens were identified, suggesting that an immunological reaction had caused the reversible liver damage through a hypersensitivity reaction to CDH.

5137 ALLOPURINOL-INDUCED GRANULOMATOUS HEPATITIS. (Eng.) Espiritu, C. R.; Alalu, J.; Glueckauf, L. G.; Lubin, J. (Mount Sinai Medical Center, Miami Beach, FL). *Am. J. Dig. Dis.* 21(9):804-806; 1976.

A second documented case of granulomatous hepatitis occurring in a 55-yr-old woman after therapy with allopurinol is reported. Four weeks after beginning treatment with allopurinol for hyperuricemia, the patient developed arthralgia, myalgia, and fever. A percutaneous liver biopsy showed the presence of small granulomas scattered throughout the hepatic lobules, but sparing portal tracts. The granulomas showed no necrosis and were composed mainly of mononuclear and multinucleated histiocytes and a few lymphocytes. There were a few scattered eosinophilic granulocytes in portal tracts and sinusoids. Shortly after allopurinol was discontinued, there was dramatic clinical improvement; liver function returned to normal, except for a persistently elevated alkaline phosphatase level (130 μU/ml). Open liver biopsy performed 9 months after cessation of allopurinol therapy demonstrated complete resolution of the granulomatous infiltrates in the liver. This case differs from the previously reported case by the absence of peripheral eosinophilia, the slow resolution of liver dysfunction, and the predominantly lobular distribution of the granulomas with sparing of the portal tracts. The persistent elevation of the alkaline phosphatase may be explained by the remaining fatty infiltration, which was seen on the repeat liver biopsy.

Acute Viral Hepatitis

5141 GLUCOSE TOLERANCE IN VIRAL HEPATITIS.

(Eng.) McIlroy, M.; Walsh, C. H.; Doyle, C.; O'Sullivan, D. J.; Whelton, M. J. (St. Finbarr's Hosp., Cork, Ireland). *Ir. J. Med. Sci.* 145(1):3-9; 1976.

The incidence and type of abnormalities of glucose homeostasis that may occur in viral hepatitis were investigated in 14 patients with confirmed viral hepatitis. Oral glucose tolerance tests (50 g glucose) were performed on all patients. All patients were jaundiced, with serum bilirubin ranging from 1.2 to 16.0 mg. SGPT was raised in all patients, ranging from 288 to 2,180 IU/l. The prothrombin index was initially increased in three patients, but returned to normal after intramuscular vitamin K treatment. Five patients had abnormal glucose tolerance tests. Two of these had an impaired insulin response to the oral glucose load. Glucose tolerance tests repeated in the anicteric phase gave normal results. The differences were significant at 30 ($p<0.02$), 60 ($p<0.001$), 90 ($p<0.01$), and 120 ($p<0.05$) min. Serum insulin levels also showed an improved response in the anicteric phase. Eight of the 14 patients had no abnormality of either blood sugar or serum insulin after oral glucose loading. There was no significant difference in the mean bilirubin, SGPT, or alkaline phosphatase levels, or prothrombin time between patients with abnormal and normal glucose tolerance. The lowest fasting blood sugar was 55 mg, recorded on a single occasion in each of five patients. The glycogen content was assessed on a subjective, visual scoring system in 10 of the 13 patients who underwent liver biopsy. It was decreased in all specimens. The glycogen scores of the patients with hepatitis were just significantly lower than those of 10 patients with other forms of liver disease studied at the same time ($p<0.05$). It is concluded that the deranged carbohydrate metabolism probably reflects a combination of stress and viral infection.

5142 FREQUENCY OF HEPATITIS IN SPECIALISTS IN ONTARIO.

(Eng.) Berris, B.; Feinman, S. V.; Sinclair, J. C.; Wrobel, D. M.; Carr, A.; Christopher, J.; Le Riche, W. H. (Suite 427, 600 University Ave., Toronto, Ontario, M5G 1X5, Canada). *Can. J. Public Health* 66(6):468-470, 1975.

The frequency of hepatitis among 4,426 physicians in Ontario was determined by questionnaire. The 574 surgeons had a higher frequency of hepatitis (12.2%) than did the 1,491 family physicians (8.9%), 141 radiologists (5.0%), and the 238 psychiatrists (5.8%), but a similar frequency to the 602 internists (10.0%), the 165 obstetricians (9.7%), the 159 pediatricians (8.8%), and the 119 pathologists (9.2%). Although epidemics of hepatitis B in some hospital areas, such as laboratory, dialysis, and operating rooms, have been described, routine preferential hepatitis B surface antigen screening of patients in selected services is not indicated.

5143 CARRIERS OF HEPATITIS B ANTIGEN AND INFECTIVITY.

(Swe.) Nordenfelt, E. (Institutionen for medicinsk mikrobiologi, Lund, Sweden). *Lakartidningen* 72(37):3411-3412; 1975.

The detection of hepatitis B antigen (HBsAg) alone does not indicate that the carrier represents a source of infection. Approximately 0.1% of apparently healthy blood donors in Sweden are chronic carriers of HBsAg. The hepatitis B virus has not been isolated, but may be contained in the so-called Dane particles. These particles contain distinct surface and core HBAg, and DNA-polymerase activity has been associated with the HBcAg of the particles. A recently discovered antigen, the e antigen, has been associated with HB virus activity, and therefore may serve as an indicator of infectivity. Coded blood sera from six donors and from six dialysis patients with highly infectious hepatitis B were clearly distinguishable, since the latter always displayed Dane particles, e antigen, or DNA polymerase (generally all three), while all but one of the former patients had, at most, a few Dane particles. The suspect donor had a history of liver disorders, and his wife subsequently developed HB. Twenty-three of 36 chronic HBsAg carriers in an institution for the mentally retarded were positive for DNA polymerase; 1 of these was also positive for e antigen, while 11 were negative. Nine of the 11 patients without DNA polymerase and e antigen showed no signs of liver damage, but 21 of the 23 patients who were positive for DNA polymerase had biochemical signs of chronic hepatitis. It seems that testing for e antigen and DNA polymerase can distinguish infectious HBAg carriers.

5144 BACKGROUND AND PRACTICAL ASPECTS OF HEPATITIS B SURFACE ANTIGEN CARRIER STATE.

(Eng.) Helske, T. (Finnish Red Cross Blood Transfusion Service, Kivihaantie 7, SF-00310 Helsinki 31, Finland). *Ann. Clin. Res.* 8(3):158-161; 1976.

The literature on the incidence of the hepatitis B surface antigen (HBsAg) carrier state and on the relationship of this state to the development of acute hepatitis is briefly reviewed, and practical measures concerning the management of carriers are discussed. The prevalence of carriers is lowest (0.1-0.2%) in Western Europe and North America, and highest (a few percent) in Oceania and Asia. The carriers are frequently young males, and the prevalence of carriers among drug addicts, prisoners, prostitutes, and patients at venereal disease clinics is higher (0.7-5.0%) than among other groups. In one study in Finland, only 8 of 583 HBsAg-positive blood donors had evidence of chronic hepatitis. However, acute hepatitis B followed by persistent HBs antigenemia usually progresses to chronic hepatitis. Familial clustering of HBsAg carriers has been described in populations with a high prevalence of carriers, such as the Pacific Ocean and on Sardinia, and also in populations with fewer carriers

LIBRARY U. OF I. [illegible]

in Finland and New York; the frequency of carriers among the relatives of index cases was 7.9% in New York and 9.6% in Finland, i.e., 10 and 50 times as high as in their general populations. A combination of environmental and genetic factors are thought to contribute to the chronic HBsAg carrier state, but the genetic factors are poorly understood. The relatives of a patient with acute hepatitis B often develop the disease, but in relatives of healthy HBsAg carriers, acute hepatitis is an exception; of 184 spouses of Finnish HBsAg carriers, only 3 developed hepatitis. Although there are 7,000-8,000 HBsAg carriers in Finland, only 114 cases of acute hepatitis were reported in 1973. It is concluded that strict occupational or social restriction of HBsAg carriers is unnecessary, except among those involved in the preparation of blood products and among blood donors.

5145 EFFECTIVENESS OF THE FLAVONOID (+)-CYANIDANOL-3 IN ACUTE VIRAL HEPATITIS. (Ger.)

Borel, G. A.; Schelling, J. L.; Magnenat, P. (Kanton-Hospitals, Universitat Lausanne, 47, Av. des Cerisiers, CH-1009 Pully, Switzerland). *Z. Gastroenterol.* 14(1):24-29; 1976.

The clinical effect of (+)-cyanidanol-3, a flavonoid with very little toxicity, was tested in 28 young patients with acute viral hepatitis in a double-blind study. The clinical diagnosis was verified by laboratory tests. Fourteen patients received 1 g of (+)-cyanidanol-3 for 2 days, then 2 g daily for an average of 21 days; the other 14 patients were given lactose placebo tablets. In another study (without controls and a double-blind trial), 18 patients received only 1 g (+)-cyanidanol-3 daily. The results indicated no statistically significant difference in symptoms between the groups. The regression of the hyperbilirubinemia in relation to time from its maximum value to its first normal value (1.2 mg/100 ml) revealed half times of 3.2 ± 0.5 days in treated patients and 4.9 ± 0.5 days in untreated ones ($p<0.05$). There was no statistical difference between the placebo group and the patients of the second study; the dosage of the second study was assumed to be too low to be effective. No other liver function tests showed statistically significant differences between the groups. The effectiveness of at least 2 g of (+)-cyanidanol-3 a day on the plasma bilirubin level in acute viral hepatitis has been confirmed by two other double-blind studies.

5146 EFFECT OF HUMAN LEUKOCYTE INTERFERON ON HEPATITIS B VIRUS INFECTION IN PATIENTS WITH CHRONIC ACTIVE HEPATITIS. (Eng.)

Greenberg, H. B.; Pollard, R. B.; Lutwick, L. I.; Gregory, P. B.; Robinson, W. S.; Merigan, T. C. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *N. Engl. J. Med.* 295(10):517-522; 1976.

The effects of human WBC interferon on specific Dane-particle markers were studied in four patients with chronic hepatitis B infection and chronic active hepatitis. Three patients had consistently elevated levels of circulating Dane-particle markers, including Dane-particle-associated DNA polymerase activity, hepatitis B core antigen, and Dane-particle-associated DNA. Parenteral (s.c., once daily in 3 patients; i.m., twice daily in 1) interferon (6.0×10^3-17×10^4 U/kg/day) administration was associated with a rapid and reproducible fall in all Dane-particle markers in the three patients. The suppressive effect was transient when the interferon was given for 10 days or less, but appeared to be more permanent when administration was prolonged for a month or more. In addition, long-term interferon therapy was associated with a marked fall in hepatitis B surface antigen in two of three patients and a disappearance of e antigen in two of two patients. In the patient without Dane-particle markers, the levels of DNA polymerase activity, hepatitis B core antigen, and Dane-particle-associated DNA remained the same throughout the study. Interferon may be useful in limiting carrier infectivity or eradicating chronic infection.

5147 PROGNOSTIC SIGNIFICANCE OF IN-VITRO COMPLEMENT FIXATION IN LIVER BIOPSY SPECIMENS FROM PATIENTS WITH ACUTE VIRAL HEPATITIS TYPE B.

(Eng.) Rizzetto, M.; Diana, S.; Bonino, F.; Verme, G. (Ospedale Mauriziano Umberto I, Corso Turati 46, 10128 Turin, Italy). *Lancet* 2(7983):436-438; 1976.

The prognostic significance of *in vitro* complement fixation (VCF) by hepatitis B core antigen/antibody immunocomplexes in hepatitis B surface antigen (HBsAg)-positive liver biopsy specimens was evaluated in 47 patients with acute viral hepatitis B. Thirty-four of 37 VCF-negative patients made an uneventful recovery and became HBsAg-negative; in 10 patients with a VCF-positive test, chronic hepatitis and persistent antigenemia developed. The VCF test is a simple and reliable prognostic indicator of persistent infection and of progression of apparently acute hepatitis to a chronic liver disorder.

5148 DEFECT OF BONE MARROW GRANULOCYTE RESERVE IN VIRAL HEPATITIS. (Eng.)

Magliulo, E.; Gallina, M.; Scevola, D.; Concia, E. (Istituto di Malattie Infettive, Universita di Pavia, Pavia, Italy). *Acta Haematol. (Basel)* 54(1):27-31; 1975.

To elucidate the pathogenesis of bone marrow failure following viral hepatitis, the etiocholanolone test for marrow granulocyte reserve was used in 16 patients with hepatitis B antigen (HBAg)-positive hepatitis and 10 patients with HBAg-negative hepatitis. Peripheral WBC counts were carried out immediately before, and 9, 12, and 15 hr after the administration of etiocholanolone (0.2 mg/kg, i.m.). The height of the WBC response was evaluated in relation to the granulocytic increment (ΔG), the difference between the preinjection value and the maximum absolute granulocyte count obtained after the injection. ΔG was considered normal when the increase in granulocytes was higher than 2,600/μl after the injection. The average ΔG of the patients during the acute phase of the disease (3.456 granulocytes/μl) and during remission (5.407 granulocytes/

µl) was significantly lower than that of 10 controls (8.675 granulocytes/µl). Three of 8 patients in the acute phase of the disease had pathologically low ΔG values, and 1 of 18 patients had a low ΔG at release from the hospital; no pathological values were found in the controls. The mean ΔG of the HBAg-positive patients in the acute phase (2.970 granulocytes/µl) and in remission (5.302 granulocytes/µl) was lower than that of the HBAg-negative patients (4.265 and 5.571 granulocytes/µl in the acute and remission phases, resp.). The results indicate that the granulocyte response is impaired in many patients with hepatitis; this impairment may be caused by a virus-induced myelotoxic or immunoallergic derangement in the process of differentiation, proliferation, or maturation of granulocyte precursors.

5149 PRIMARY LIVER CANCER AND HEPATITIS B INFECTION IN SENEGAL. COMPARISON OF CANCER PATIENTS WITH TWO CONTROL GROUPS. (Fre.) Michon, J.; Prince, A. M.; Szmuness, W.; Demaille, J.; Diebolt, G.; Linhard, J.; Quenum, C.; Sankale, M. (Clinique Medicale, Faculte de Medecine, Dakar, Senegal). *Biomedicine* 23(7):263-266; 1975.

To determine the prevalence of hepatitis B surface antigen (HBsAg) and antibody (anti-HBs) in primary liver cancer (PLC), 165 patients with PLC, 154 age- and sex-matched controls with other cancers (COC), and 328 controls without cancer (CWC) were examined by radioimmunoassay and passive hemagglutination. The antigen was found in 61.2% of PLC, 11.7% of COC, and 11.3% of CWC. Anti-HBs was found in 18.2% PLC, 45.4% COC, and 42.1% CWC. In PLC patients, the frequency of HBsAg was significantly greater in those with positive α-fetoprotein (72.2%) than in those without it (40.3%). In view of the very early age for viral contamination in Senegal (maximal antigenemia at 5-6 yr), the HB infection probably precedes the hepatoma. The hepatoma may be the result of a direct oncogenic action of the virus. However, other factors such as hormones (predominance of men), pathological background (viral, bacterial, and parasitic infections), and nutritional state of health are probably also involved.

5150 COXSACKIE HEPATITIS IN AN ADULT, WITH ULTRASTRUCTURAL DEMONSTRATION OF THE VIRUS. (Eng.) Gregor, G. R.; Geller, S.; Walker, G. F; Campomanes, B. A. (Mount Sinai Hosp., Dept. Pathology, 100th St. and Fifth Ave., New York, NY 10029). *Mt. Sinai J. Med. N.Y.* 42(6):575-580; 1975.

The case of a 28-yr-old man with Coxsackie B virus infection, myocarditis, pericarditis, and myositis is reported. Rising serologic titers to Coxsackie B, types 2 and 5, were documented; the antibody titers to Coxsackie B2 were 1:256, 1:512, and 1:1024 on days 6, 13, and 27, resp., and to Coxsackie B5 were, resp., 1:32, 1:128, and 1:128. The clinical course was complicated by hepatitis, which was fatal. Liver biopsy prior to clinically obvious hepatitis showed microabscesses. At autopsy, inflammation was present in the heart, striated muscles, and liver. The hepatic tissue obtained at the time of biopsy, when serologic titers to Coxsackie virus were at a peak, was reprocessed for electron microscopy. Particles, identical to those previously documented as Coxsackie virus, were abundant in the liver cells.

5151 CLINICAL PATHOLOGIC CORRELATION IN VIRAL HEPATITIS: THE EFFECT OF THE VIRUS ON THE LIVER. (Eng.) Popper, H. (Mount Sinai Sch. Medicine, City Univ., New York, NY 10029). *Am. J. Pathol.* 81(3):609-628; 1975.

The clinical pathologic correlations in viral hepatitis are reviewed. With acute hepatitis, correlation with clinical features and functional defects is good. This is less true in chronic hepatitis. The pathology of hepatitis, including cell necrosis, fibrosis, cirrhosis formation, and inflammation is understood well enough to be useful in prognosis and monitoring of the disease during therapy. While still preliminary, the localization of the components of the hepatitis B antigen and their effects, including the nature of the immune response, may soon lead to further clarification of the pathogenesis and evolution of viral hepatitis.

Chronic Hepatitis

5173 CHRONIC HEPATITIS: PRACTICAL GUIDELINES FOR DIAGNOSIS AND TREATMENT. (Dut.) Vogten, A. J. M.; Brandt, K.-H.; Bronkhorst, F. B. (Afdeling Gastro-Enterologie, Academisch Ziekenhuis te Utrecht, Utrecht, Netherlands). *Ned. Tijdschr. Geneeskd.* 119(33):1277-1282; 1975.

Because of the multiplicity of possible manifestations, chronic hepatitis is extremely difficult to define and differentiate from other diseases. In chronic persistent hepatitis, inflammatory infiltrate, consisting primarily of mononuclear cells, is present in the portal vessels; in chronic aggressive hepatitis, the inflammatory process is not limited to the portal vessels, but the parenchyma is also involved. Anamnestic factors discovered in a retrospective survey of 80 chronic hepatitis patients included pathological fatigue in 69, icterus in 40, abdominal pain in 40, presumed virus exposure in 33, itching in 20, hepatotoxic drug use in 9, fever or subfebrile temperature in 6, menstruation disorders in 5 of 52 women, and malfunction of organs other than the liver in 18. The following findings were obtained in general physical examinations of these 80 patients: liver enlargement in 33, palpable spleen in 23, spider nevi in 19, palmar erythema in 10, ascites in 9, and rectal varices in 7. Some chronic hepatitis patients with hepatitis B antigen in the serum may benefit from immunosuppressive treatment; in others, only careful monitoring is indicated. Treatment of patients with a hyperimmune type illness should begin with 2-4 weeks of strict bed rest, followed by the minimum dose of prednisone necessary to suppress disease activity. Preventing cirrhosis development is of major importance.

5174 PROGNOSIS OF CHRONIC HEPATITIS. (Eng.) Krieg, D.; Weigl, E.; Bach, H. (Hospital Eisenhuttenstadt, DDR-1220, Eisenhuttenstadt, E. Germany). *Acta Hepatogastroenterol.* 23(3):168-172; 1976.

The chronic diseases occurring in patients who had had hepatitis were investigated in 1,419 cases of acute viral hepatitis. These cases occurred during a 10-yr period among 66,211 residents of a rural district in Germany. Of the 1,283 patients who were followed up, 1,079 had completely recovered after 18 months. Of the remaining patients, chronic persistent hepatitis developed in 80, chronic aggressive hepatitis in 4, cirrhosis in 6, hyperbilirubinemia in 66, fatty liver in 3, and alcoholic liver in 9 patients. Defective states after hepatitis occurred in 28 patients, and undiagnosed pathologic cases were recorded in 8 patients. The transition to chronic hepatitis occurred more frequently in older patients; chronic hepatitis occurred in less than 1% of the preschool-aged children, in 10% of the young adults, and in 14% of the middle-aged adults. Forty-five patients with chronic persistent hepatitis recovered within 5 yr. Two of four patients with chronic aggressive hepatitis developed cirrhosis. Patients with viral hepatitis should be followed up to diagnose the chronic sequelae and to control the severe cases.

5175 SALIVARY AND DUODENAL AMYLASE PRODUCTION IN PATIENTS WITH CHRONIC HEPATIC DISEASES. (Ger.) Gladisch, R.; Maiwald, L. (Medizinische Klinik der Universitat Wurzburg, Luitpoldkrankenhaus, Josef-Schneider-Strasse 2, 8700 Wurzburg, W. Germany). *Med. Klin.* 71(9):373-377; 1976.

A generally symmetrical swelling of the parotid glands is sometimes seen in patients with chronic liver disease, but the cause has not yet been determined. Disturbances of excretory pancreas function are also common in liver disease. In view of the similarities of neural regulation of these two symptoms, amylase secretion was examined in 35 patients with various liver diseases, resulting in BSP retention levels of 0-5% (group 1), 5-10% (group 2), or more than 10% (group 3). Duodenal fluid and saliva were collected simultaneously for 60 min following infusion of pancreozymin (100 U) and secretin (90 U). The majority (8/13) of patients in group 1 had normal duodenal secretion volumes. In group 2, 80% of the patients had high normal secretion or hypersecretion levels. Six of the seven patients in group 3 had distinctly reduced (subnormal or low normal) secretion values. The changes in saliva production were the inverse of the changes in pancreatic secretion in the three groups; the largest saliva volumes were collected from group 3. The amylase production in each case paralleled the volume of secretion, and amylase production by the parotids increased with declining secretion by the pancreas. Some of the patients in group 2 deviated from this overall pattern. The findings support the association of liver and pancreatic abnormalities and confirm the increase in saliva production with progressive pancreatic insufficiency probably via hormonal mechanisms.

5176 DISORDERS OF CARBOHYDRATE METABOLISM IN CHRONIC HEPATITIS AND CIRRHOSIS OF THE LIVER. (Slo.) Danko, M.; Spanar, E.; Holan, J.; Zahradny, V.; Kurocka, J. (LF UK, ul. Vychodna 2-14, Sever, Martin 1, 036 01 Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 28(3):173-177; 1974.

Glucose tolerance and the role of endogenous plasma insulin were investigated in patients with disorders of carbohydrate metabolism, chronic hepatitis, and cirrhosis. Sixty and 120 min after glucose administration (0.5 g/kg, i.v.), the blood sugar level was significantly increased in 10 patients with chronic hepatitis and cirrhosis over 11 controls. The slope of the blood sugar level curve was also pathologically altered in the patients, while the glucose utilization coefficient was significantly lowered ($p<0.05$) in 70% of them. The plasma level of total immunoreactive insulin was significantly increased during fasting and 120 min after glucose administration in patients with liver diseases ($p<0.05$). Disturbances in carbohydrate metabolism were reflected in plasma hyperglycemia and hyperinsulinemia, not only during fasting, but also after an i.v. glucose tolerance test (GTT). Evaluation of the i.v. GTT using the utilization coefficient was a more

LIBRARY U. C.

reliable index of disturbed glucose tolerance in cirrhosis patients than the p.o. GTT was. The blood sugar level 60 and 120 min after the i.v. GTT was a more reliable index than the blood sugar level during fasting. Disturbances in hepatic circulation and microcirculation and decreased peripheral utilization of glucose were among the causes of the disturbance in carbohydrate metabolism observed in patients with liver diseases. The metabolic disturbance probably plays an important role in the development of secondary clinical disturbances, the decrease in resistance to stress, and the development of secondary infections.

5177 CHRONIC HEPATITIS FOLLOWING THE USE OF DRUGS. (Dut.) Vogten, A. J. M. (Afdeling Gastroenterologie, Academisch Ziekenhuis te Utrecht, Utrecht, Netherlands). *Ned. Tijdschr. Geneeskd.* 120(17):755-760; 1976.

A great variety of drugs has been reported to cause chronic hepatitis. Criteria for diagnosing this condition include chronic drug use, a hepatitis-like reaction caused by the use of the drug, and the absence of acute liver necrosis and hypersensitivity reactions. Biochemical studies have suggested that one or more of the following mechanisms might account for the pathogenesis of this condition: conversion of the drug into a toxic metabolite, a direct toxic action of the drug on protein and fat metabolism in the liver cell, immunologic effects of the drug, and drug-induced suppression of bile secretion. The symptomatology is similar to that of other forms of chronic hepatitis, but may be more varied. The histological picture is that of an aggressive periportal hepatitis. Some investigators maintain that the histological abnormalities are more focally localized in the liver in the case of chronic drug-induced hepatitis than in other forms. Treatment comprises cessation of drug administration; steroids should be reserved for the most severe reactions. The prognosis depends on the rapidity with which the disease develops, and ranges from complete regression of symptoms to death. Hepatotoxic drugs should be avoided, if possible, or if required, should be carefully monitored.

5178 AGGRESSIVE EMPERIPOLESIS IN CHRONIC HEPATITIS. (Ger.) Bechtelsheimer, H.; Gedigk, P.; Muller, R.; Klein, H. (Pathologisches Institut der Universitat, Postfach, D-5300 Bonn 1, W. Germany). *Klin. Wochenschr.* 54(3):137-140; 1976.

Aggressive emperipolesis was examined quantitatively by conventional microscopy in biopsy specimens from 74 patients with chronic hepatitis. The enumeration was based on the reaction between effector and target cells, which was indicated by the presence of an areola around the embedded lymphocyte, or in later stages of the reaction, by necrosis of the affected hepatocyte. Emperipolesis was evident in all of the specimens obtained from 36 patients with chronic aggressive hepatitis; 10 or more emperipolesis were found in the surroundings of the portal fields. Fewer than 10 emperipolesis were counted in specimens from each of the 48 chronic persistent hepatitis cases; no emperipolesis were seen in nine of the cases. Specimens containing 9-12 emperipolesis were obtained from borderline hepatitis cases, which were difficult to designate as chronic or aggressive based on clinical criteria. Aggressive emperipolesis provides an additional criterion for distinguishing the two principal types of chronic hepatitis.

5179 CRYOPROTEIN COMPLEXES AND PERIPHERAL NEUROPATHY IN A PATIENT WITH CHRONIC ACTIVE HEPATITIS. (Eng.) Farivar, M.; Wands, J. R.; Benson, G. D.; Dienstag, J. L.; Isselbacher, K. J. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 71(3):490-493; 1976.

A cryoprotein complex isolated from the serum of a 59-yr-old woman with chronic active hepatitis and severe peripheral neuropathy was characterized. Electromyography demonstrated a severe peripheral neuropathy, which was most pronounced in the right lower extremity. A liver biopsy showed changes typical of chronic active hepatitis and early postnecrotic cirrhosis. Biopsy of the gastrocnemius showed a type II degeneration, with normal muscle interspersed with atrophic cells and no evidence of vasculitis. These changes did not suggest a myopathy and were considered secondary to the neuropathy. The cryoprotein was composed of immunoglobulin M (IgM), IgG, and hepatitis B surface antigen (HBsAg) and had a concentration of approximately 36 mg/100 ml of serum. Electron microscopic examination of the cryoprotein demonstrated aggregates of Dane particles in close association with the antigenically related tubular and spherical forms of HBsAg. HBsAg, IgM, and IgG were detected by immunofluorescent staining in the intima of small arteries and veins. The association of a high serum level of cryoprotein and deposition of the cryoprotein components in small blood vessels suggests a role for the cryoprotein in the pathogenesis of peripheral neuropathy in chronic active hepatitis.

5180 CHRONIC HEPATITIS: PRESENT CONCEPTION. (Fre.) Traissac, F.-J.; Lamouliatte, H.; Weber, F.; Borg, R. (No affiliation given). *Bordeaux Med.* 8(9):1031-1038, 1040-1041, 1043-1048; 1975.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

5190 INCREASE IN TYPE I AND TYPE III COLLAGENS IN HUMAN ALCOHOLIC LIVER CIRRHOSIS. (Eng.) Rojkind, M.; Martinez-Palomo, A. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, New York, NY 10461). *Proc. Natl. Acad. Sci. USA* 73(2):539-543; 1976.

Previous studies have indicated that the cirrhotic liver contains increased amounts of type III collagen, but not type I collagen; experiments were conducted to determine if type I collagen is also increased in the livers of cirrhotic patients. About 30% of the total collagen was isolated postmortum from the livers of one person without liver disease and from the livers of three persons with alcoholic cirrhosis. Analyzed chemically and examined by electron microscopy, the collagen in each case was shown to consist of two types identical with, or resembling closely, type I and type III collagens of skin. The collagen from normal liver was predominantly type I, whereas that from cirrhotic livers consisted of approximately equal amounts of the two types. By carboxymethyl-cellulose chromatography, the type I collagen from the cirrhotic livers showed one α2 chain and two α1 chains. The α1 chains were separable from one another, but gel electrophoretic patterns of peptides obtained from them after digestion with a 10-fold excess of cyanogen bromide (CNBr; 3 mg protein) were almost identical, and resembled the pattern obtained with CNBr peptides of the α1 chain of rat skin type I collagen. The increased collagen of both types was responsible, in part, for the observed distortion of the architecture of the cirrhotic livers associated with increased rigidity of the stroma. The predominance of type III collagen in the areas of collapse of architecture suggests that hepatocytes might have an important function in fibrogenesis during the course of liver cirrhosis.

5191 INHIBITION OF ETHANOL OXIDATION ON PROLONGED FASTING IN MAN: REVERSIBILITY OF FRUCTOSE INFUSION. (Ger.) Bode, J. C.; Thiele, D. (Medizinische Universitatsklinik Marburg, Marburg, Germany). *Dtsch. Med. Wochenschr.* 100(37):1849-1851; 1975.

To determine the degree of inhibition of ethanol oxidation by prolonged fasting, ethanol (0.5 g/kg, i.v., in 400 ml of 0.9% NaCl) was administered to healthy 12- or 36-hr fasted subjects. The alcohol concentration was measured before and during i.v. administration of glucose (0.7 g/kg/hr in a 10% w/v solution) to find out whether the inhibition of alcohol oxidation is reversible through increased NADH reoxidation. An average 43% ($p<0.01$) decrease of alcohol oxidation was seen after 36 hr, compared to 12 hr fasting. This decrease was not observed if fructose was given i.v. The authors conclude that the inhibition of alcohol oxidation in prolonged fasting is caused by decreased reoxidation of NADH in the liver.

LIVER AND BILIARY TRACT

Cirrhosis

5200 THE BILIARY SYSTEM IN PRIMARY BILIARY CIRRHOSIS: A STUDY BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) Summerfield, J. A.; Elias, E.; Hungerford, G. D.; Nikapota, V. L. B.; Dick, R.; Sherlock, S. (Royal Free Hosp., Pond St., London, NW3 2QG, England). *Gastroenterology* 70(2):240-243; 1976.

Endoscopic retrograde cholangiograms from 23 patients with primary biliary cirrhosis (PBC), 10 controls with either normal livers or hepatocellular disease, and 4 patients with sclerosing cholangitis were compared, and the changes were correlated with the duration of the disease, the hepatic histology, and the presence of gallstones. Of the PBC group, 39% had gallstones. The calibers of the common bile duct and left and right intrahepatic ducts were comparable in the PBC and control groups. The small intrahepatic ducts were normal in the control group, but were abnormal in 7 of the 23 PBC patients. These small ducts were irregular in caliber and had a tortuous course. The changes were not related to the presence of gallstones or the duration of the disease, but all the patients had histologically proven cirrhosis. Two patients with cirrhosis had normal intrahepatic ducts. Although the major bile ducts are normal in PBC, there was a high incidence of gallstones (39%), and the changes that did occur in the intrahepatic ducts were probably related to the distorted hepatic architecture due to cirrhosis. The changes may be used as a sign that cirrhosis has supervened.

5201 EXTRACTION OF ^{125}I-ALBUMIN MICROAGGREGATES FROM PORTAL BLOOD. AN INDEX OF FUNCTIONAL PORTAL BLOOD SUPPLY IN CIRRHOTICS. (Eng.) Huet, P.-M.; Marleau, D.; Lavoie, P.; Viallet, A. (Hospital Saint-Luc, 1058 St-Denis, Montreal, Quebec, Canada). *Gastroenterology* 70(1):74-81; 1976.

To investigate the process of uptake by Kupffer's cells, the multiple indicator dilution technique was used in normal dogs, in patients with alcoholic cirrhosis, and in patients with idiopathic noncirrhotic portal hypertension (IPH). Portal and hepatic indicator dilution curves (IDC) were obtained after injection of a mixture of ^{51}Cr-labeled RBC and ^{125}I-albumin microaggregates (^{125}I-AMA) into the cranial mesenteric artery in 15 dogs. The extraction (E) of ^{125}I-AMA from portal blood was measured during one passage through the hepatic reticuloendothelial system. Using [^{51}Cr]RBC as a vascular reference substance, E-^{125}I-AMA was calculated by comparing simultaneous [^{51}Cr]RBC and ^{125}I-AMA portal and hepatic IDC and was expressed as the percentage of ^{125}I-AMA flowing through the portal vein. In 44 experiments (15 dogs), the colloid was almost completely extracted (E-^{125}I-AMA=92.3 ± 1.0%). This approach was applied in 15 patients with severe portal hypertension undergoing combined umbilicoportal, hepatic vein, and superior mesenteric artery catheterization. Eleven patients had alcoholic cirrhosis (AC) and four patients had IPH. Using [^{51}Cr]RBC-IDC, the portal fraction of hepatic blood flow varied between 34.1 and 100% (mean 62.6%) in AC patients and between 56.5 and 91.2% (mean 74.2%) in IPH patients. E-^{125}I-AMA varied from 5.2 to 100% (mean 45.1%) in AC patients, although normal values were obtained in IPH patients (mean 93.2%). The extraction of indocyanine green (E-ICG) was calculated for all patients using a continuous infusion for the estimation of hepatic blood flow. E-ICG was decreased in AC patients (mean 22.1%), although normal values were obtained in IPH patients (mean 49.5%). A significant correlation was found between E-^{125}I-AMA and E-ICG ($r=0.977$, $p<0.001$). A significant correlation between E-^{125}I-AMA and the relative clearance of ICG ($r=0.906$, $p<0.001$) was found in all patients. The correlations between the extraction or clearance of substances removed by two different cell populations suggest that their decreases are mainly due to changes in liver microcirculation. In cirrhotics, the decreased E-^{125}I-AMA can be related to part of the portal blood by-passing Kupffer's cells (intrahepatic portohepatic shunts) and/or to sinusoidal changes responsible for ineffective phagocytosis. Thus, E-^{125}I-AMA can be used as an estimation of the functional portal blood supply to the liver in cirrhotics. Using portal and hepatic IDC after injection of [^{51}Cr]RBC and ^{125}I-AMA into the superior mesenteric artery, the portal fraction of hepatic blood flow and the functional portal blood supply can be estimated simultaneously in patients with portal hypertension before portacaval shunts.

5202 INDIAN CHILDHOOD CIRRHOSIS OF THE LIVER: A MORPHOLOGIC EVALUATION. (Eng.)

Mehrotra, M. L.; Gupta, S.; Gupta, I. M.; Bhargava, V.; Katiyar, G. P. (Inst. Medical Sci., Banaras Hindu Univ., Varanasi, India). *Trop. Geogr. Med.* 27(4): 333-338; 1975.

The morphological changes in various stages of Indian childhood cirrhosis of the liver (ICC) were studied histologically in biopsy specimens from 44 children. Ballooning and feathery degeneration of hepatocytes, complete absence of fatty change, frequent occurrence of intracytoplasmic hyaline bodies, dissection of pseudolobules by fibrous septa, and fibrosis around single cells were notable features. A few cases also showed giant-cell transformation and pseudoadenomatous arrangement of hepatocytes. These observations suggest that the basic morphologic alterations in ICC are diffuse liver cell damage and replacement fibrosis, the latter of which may be due to some toxic factor.

5203 EFFECT OF AN ANABOLIC STEROID (METHENOLONE ENANTHATE) ON THE INTRA- AND EXTRAVASAL ALBUMIN POOL IN LIVER CIRRHOSIS. (Ger.)

Knobel, H.; Becker, L. (Augenklinik und Poliklinik, 2 Hamburg 20, Martinistrasse 52, W. Germany). *Z. Gastroenterol.* 13(6):583-587; 1975.

To determine whether the anabolic steroid, methenolone enanthate, increases serum albumin levels, 15 patients (aged 20-67 yr) with compensated liver cirrhosis and statistically proven decreased daily albumin turnover (0.129 ± 0.039 g/kg/) were treated with methenolone enanthate (200 mg/week) for 4 weeks. In addition, the possibility that the increased serum albumin levels were due to a shift from the extra- to the intravascular pool or were the result of a real increase in the total body albumin pool was investigated. Five normal controls had albumin metabolism rates of 0.172 ± 0.035 g/kg. None of the patients had ascites, edema, or icterus. The daily turnover rate and the intra- and extravascular pool before and after treatment were determined through indirect measurement with iodine-125 albumin. The results of this study do not support the hypothesis that although anabolic steroids improve albumin synthesis, they establish an equilibrium between extra- and intravascular space. Methenolone enanthate increased the daily albumin turnover in the patients with cirrhosis of the liver from 0.129 ± 0.039 g/kg to 0.140 ± 0.043 g/kg; the increase was proportional to the amount of reduction before treatment.

5204 ENDOTOXEMIA IN LIVER CIRRHOSIS. (Ger.)

Liehr, H.; Gruen, M.; Brunswig, D.; Sautter, T. (Med. Univ. Klinik, D-8700 Wurzburg, Josef-Schneider-Strasse 2, W. Germany). *Z. Gastroenterol.* 14(1):14-23, X; 1976.

The incidence, progress, and significance of endotoxemia were examined in 29 patients with cirrhosis of the liver, mostly of alcoholic origin, confirmed by laparoscopy and histologic examination. More or less extensive portacaval collaterals were present in most cases. Nine of the patients were hospitalized for hemorrhage from esophageal varices, and 14 for generalized deterioration. The limulus gelation test was negative in control plasmas, but gave positive results in 115 of the 292 plasma samples collected from the cirrhosis patients. Endotoxemia was already present at the time of hospitalization in 19 patients and developed during observation in another 4 patients; it was demonstrated in 79%. Positive results in the limulus test were linked with clinical manifestations, such as bleeding varices (positive in 78%), functional renal impairment (75%), consumption coagulopathy (81%), and pyrogenic reaction (82%). Comparison of the patterns of symptoms in patients with and without endotoxemia yielded no detectable differences. The dilution method of the limulus test was found to be more sensitive for free endotoxemia than the chloroform method. A quantitative test method for endotoxin would permit improved differentiation.

5205 HEPATITIS B ANTIGEN IN LIVER CIRRHOSIS AND HEPATOCELLULAR CARCINOMA. (Eng.)

Bartok, I.; Decastello, A. (Peterfy Hosp., P.O. Box 76, H-1441 Budapest, Hungary). *Acta Hepatogastroenterol.* 22(6):379-386; 1975.

The frequency of hepatitis B antigen (HBAg) among 43 patients with cirrhosis, 18 of whom had primary hepatocellular carcinoma, was determined at autopsy, and morphological changes related specifically to the presence of HBAg in the cirrhotic liver were sought. HBAg and its antibody, anti-HB, were determined by counter-electrophoresis in blood samples taken at autopsy from these patients and from 120 patients who died of other diseases (age-matched controls). HBAg was detected in the sera of six patients with cirrhosis and one control. Of 25 cases of macronodular cirrhosis, HBAg was associated with the active form in 3 cases and with the inactive form in 2 cases. One HBAg-positive patient with active macronodular cirrhosis also had hepatocellular carcinoma. Another HBAg-positive patient was among 13 patients with alcoholic micronodular cirrhosis. HBAg was not found in the one patient with secondary biliary micronodular cirrhosis or in four patients with unclassified cirrhosis. Anti-HB was not found in any of the patients or controls. The results suggest that the persistence of the hepatitis B virus is not of major importance in tumor genesis. It seems that liver cirrhosis rather than this virus, plays a primary role in the development of hepatocellular carcinoma.

5206 LYMPHOCYTE CYTOTOXICITY AND INHIBITION STUDIED WITH AUTOLOGOUS LIVER CELLS: OBSERVATIONS IN CHRONIC ACTIVE LIVER DISEASE AND THE PRIMARY BILIARY CIRRHOSIS SYNDROME. (Eng.)

Geubel, A. P.; Keller, R. H.; Summerskill, W. H. J.; Dickson, E. R.; Tomasi, T. B.; Shorter, R. G. (Cliniques Universitaires St. Pierre, Univ. Louvain, Louvain, Belgium). *Gastroenterology* 71(3):450-456; 1976.

A method for determining the cytotoxicity of normal and autologous lymphocytes for ^{51}Cr-labeled isolated parenchymal liver cells in a low aggressor-to-target cell ratio is described. The results from 25 patients with chronic active liver disease (CALD), 5 patients with chronic persistent hepatitis, 15 patients with miscellaneous liver disease, and 20 patients with primary biliary cirrhosis (PBC) were compared, and the hypothesis that *in vivo* lymphocyte-mediated liver cell damage occurs in CALD and PBC was tested. ^{51}Cr-labeled parenchymal cells (minimum, 5×10^4; mean, 10×10^4 cells) were mixed with either autologous (test) or normal (control) lymphocytes in a lymphocyte-to-target cell ratio of 10:1; after 4 hr of incubation at 37 C, the radioactivity in the supernatant of the suspension after centrifugation at 160 x *g* was determined. In 53% of CALD patients, the lymphocytes showed greater cytotoxicity for hepatic cells than did normal allogenic lymphocytes, but in 32% there was significantly less ^{51}Cr release than normal; in the remainder of CALD patients, the results were in the normal range. Lymphocyte cytotoxicity was greater in patients with disease of short duration and less in those treated with corticosteroids. In untreated CALD patients, decreased ^{51}Cr release was associated with the presence of plasma factor(s) inhibiting phytohemagglutinin (PHA)-induced transformation of normal lymphocytes. Lymphocytes from approximately 50% of the patients with PBC exhibited cytotoxicity for hepatic cells; however, 25% showed less ^{51}Cr release than did controls, and the remaining patients had results in the normal range. Lymphocyte cytotoxicity was also greater during the earlier stages of PBC. In contrast to CALD, decreased ^{51}Cr release was not associated with the presence of plasma factor(s) inhibiting PHA-induced transformation of normal lymphocytes. These findings support the hypothesis of *in vivo* lymphocyte-mediated liver cell damage in CALD and PBC, suggesting a potentially important role for lymphocyte suppression in the pathogenesis of both diseases.

5207 HEMODYNAMIC RESPONSE TO ACUTE TREATMENT WITH LEVODOPA IN CIRRHOTIC PATIENTS. (Ita.)

Butti, A.; Borzone, A.; Nanni, G.; Cagossi, M.; Bianco, A.; Civello, I. M.; Lojacono, L. (Istituto di Clinica Chirurgica Generale e Terapia Chirurgica, Universita Cattolica del Sacro Cuore, Rome, Italy). *Chir. Patol. Sper.* 23(3):123-138; 1975.

Twenty cirrhotic patients in hepatic coma were treated with 1 g L-dopa, p.o., to determine its effects on hemodynamics. There was an initial decrease in cardiac parameters ($p<0.05$ for heart rate and cardiac index, and $p<0.001$ for stroke work and mean blood pressure) and in peripheral parameters (negligible for total peripheral resistance and consumption of O_2/m^2, $p<0.001$ for arterovenous difference in O_2). However, after about 90 min, the peripheral parameters increased while the cardiac parameters continued to decrease. A biphasal action of L-dopa is hypothesized, with an initial alteration of the cardiac to peripheral parameters ratio, followed by an improvement in the tissue perfusion indices. This is interpreted as the effect of an initial mass action of L-dopa, which is caused by false neurotransmitters, and which consumes itself early. The hypothesis is supported by a late rise in the arterovenous difference in O_2 and in the venous CO_2 pressure, and by a decrease in relative peripheral shunting and ventricular function towards the end of the experiment (150-180 min).

5208 PORTAL HYPERTENSION AND PRIMARY BILIARY CIRRHOSIS. (Eng.)

Lebrec, D.; Sicot, C.; Degott, C.; Benhamou, J.-P. (Unite de Recherches de Physiopathologie hepatique [Inserm], Hopital Beaujon, F-92110 Clichy, France). *Digestion* 14(3):220-226; 1976.

Twenty-four patients with primary biliary cirrhosis (PBC) were investigated to determine the frequency of portal hypertension and whether the presinusoidal or postsinusoidal type hepatic block is responsible for portal hypertension. In addition, the relation of portal hypertension to the development of true cirrhosis, the clinical manifestations of portal hypertension, and the value of surgical portacaval shunt in the treatment of portal hypertension in PBC was studied. Esophageal varices were present in 20, 50, and 90% of the patients 1, 3, and 9 yr, resp., after the onset of pruritus and/or jaundice. Portal hypertension was responsible for gastrointestinal bleeding in 11 patients; bleeding was the first clinical manifestation of PBC in two of them. Wedged hepatic venous pressure was increased in all of the 14 patients with portal hypertension tested (≥ 5 mm Hg), whether regenerative nodules were present or absent; the mean value for the gradient between wedges and free hepatic venous pressures in 7 patients with regenerative nodules was 17 mm Hg and for those without nodules, 7 mm Hg ($p<0.01$). Portacaval shunt was performed in five patients and was well tolerated in three of them. One patient died from liver failure 3 months after surgery and was found to have regenerative nodules in the liver specimen. Pruritis combined with jaundice, and episodes of hepatic encephalopathy were complications arising in other patients following surgery. It is concluded that portal hypertension is common in PBC; that the intrahepatic block is of the so-called postsinusoidal type, even in patients without regenerative nodules; that gastrointestinal bleeding due to portal hypertension occurs in about half of the patients and may be the first manifestation of PBC; and that portacaval shunt seems to be indicated when gastrointestinal bleeding occurs in the earlier stage of the disease.

5209 URINARY AND SERUM OCTOPAMINE IN PATIENTS WITH PORTAL-SYSTEMIC ENCEPHALOPATHY. (Eng.) Manghani, K. K.; Lunzer, M. R.; Billing, B. H.; Sherlock, S. (D/8 Ferreira Mansion, Sitla Devi Temple Road, Mahim, Bombay 16, India). *Lancet* 2(7942):943-946; 1975.

To determine the usefulness of the measurement of octopamine as a marker of hepatic encephalopathy, its urinary excretion and serum concentration were studied in 17 controls, 33 patients with portal-systemic encephalopathy, and 13 patients with liver disease without encephalopathy. The assay of urinary octopamine depended upon the conversion of β-hydroxylated amines to their ^{14}C-N-methyl derivatives by the action of phenylethanolamine-N-methyltransferase in the presence of ^{14}C-S-adenosyl methionine. No significant differences were detected between control subjects and patients without encephalopathy. The urinary excretion of octopamine was significantly higher in patients with encephalopathy (mean, 148.4 μg/24 hr), compared with those without encephalopathy (66.2 μg/24 hr). Serum octopamine was also elevated in the patients with encephalopathy (16.4 ng/ml) in comparison to controls (4.6 ng/ml) and patients without encephalopathy (5.1 ng/ml). When the means for urinary octopamine excretion were compared among patients with encephalopathy, a significant increase was evident between patients in precoma (grades 1-3) and in coma (grade 4), between grade 0 and grade 1, and between grade 3 and grade 4. In five patients with encephalopathy, an improvement in the grade of encephalopathy was accompanied by a fall in the urinary excretion or serum concentration of octopamine. The measurement of octopamine in patients with liver disease may be used as a marker of hepatic encephalopathy. Octopamine may be involved in the pathogenesis of portal-systemic encephalopathy.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

5229 INFLUENCE OF THE DEFERENT BILE DUCTS ON BILE ACID COMPOSITION. INVESTIGATIONS IN PATIENTS WITH CHOLESTEROL CALCULI AND IN A NORMAL CONTROL GROUP. (Ger.) Bruhl, W. (I. Medizinische Klinik, Med. Hochschule, D-2400 Lubeck, Kronsforder Allee 71/73, W. Germany). *Z. Gastroenterol.* 13 (8):690-694; 1975.

To determine whether the deferent bile ducts influence the composition of the bile acids, changes in the composition of bile acids were compared from liver cell to gallbladder. The bile acids were examined by spectrophotofluorometry after thin-layer chromatography in 24 cadaver livers and gallbladders. Half of the organs were taken from patients with cholesterol calculi, all of which showed chronic inflammatory changes in the gallbladder. The cholic, deoxycholic, and chenodeoxycholic acid concentrations in the hepatic tissue were 1.72 ± 0.59, 1.30 ± 0.48, and 2.81 ± 1.01 μg/100 mg, resp., in the gallstone patients, and 3.88 ± 0.9, 2.09 ± 0.91, and 4.74 ± 1.29 μg/100 mg, resp., in the normal subjects. The ratio between cholic acid and deoxycholic acid plus chenodeoxycholic acid was significantly lower in the liver tissue and gallbladder than in the control group. Bile acid concentrations were decreased only in the liver tissue of the gallstone-bearing cadavers. Although there was a clear-cut correlation between bile acid concentrations in the liver tissue and the gallbladder in the control group, no correlation was found in the organs of the gallstone-bearing cadavers. It is assumed that the inflammation of the gallbladder accompanying cholesterol calculi influences the bile acid composition.

5230 COMPOSITION OF BILIARY LIPIDS AND KINETICS OF BILE ACIDS AFTER CHOLECYSTECTOMY IN MAN.

(Eng.) Kimball, A.; Pertsemlidis, D.; Panveliwalla, D. (Roosevelt Hosp., 428 W. 59 St., New York, NY 10019). *Am. J. Dig. Dis.* 21(9):776-781; 1976.

Because of conflicting reports regarding the composition of biliary lipids and the kinetics of bile acid metabolism after cholecystectomy, postcholecystectomy biliary lipid composition and bile acid kinetics were studied in 24 women and 4 men. Hepatic bile was collected periodically for as long as 4 months without interrupting the enterohepatic circulation and without infecting the biliary system. In 23 patients with cholesterol gallstones, fasting biliary cholesterol made up 10.2% of total lipids in the steady state; in 5 patients with bilirubinate stones, saturation of fasting hepatic bile with cholesterol was lower (8.7% of total lipids). The percentage of deoxycholic acid after cholecystectomy (21% of total bile acids) was not significantly higher than that of seven healthy, noncholecystectomized controls (26%). Postcholecystectomy studies of diurnal variation of biliary lipids in seven patients showed that the postprandial hepatic bile had a cholesterol saturation (mean=7.9%) that was significantly lower than fasting bile (11.2%). Pool sizes of cholic and chenodeoxycholic acids were low (average 0.4 g/70 kg, each). Total synthesis for both bile acids was normal (average 460 mg/day/70 kg), but fractional turnover rates of the two primary bile acids increased after cholecystectomy, probably due to more frequent recycling of the small bile acid pool. This study supports the view that in most patients with cholesterol gallstones, the formation of lithogenic bile by the liver is not corrected by cholecystectomy.

5231 ANTIBIOTICS IN BILIARY DISEASE: THE RELATIVE IMPORTANCE OF ANTIBIOTIC CONCENTRATIONS IN THE BILE AND SERUM.

(Eng.) Keighley, M. R. B.; Drysdale, R. B.; Quoraishi, A. H.; Burdon, D. W.; Alexander-Williams, J. (General Hosp. and Univ. Birmingham, Birmingham, England). *Gut* 17(7): 495-500; 1976.

A randomized controlled trial was performed in 150 patients undergoing biliary operations to determine whether rifamide, an antibiotic that is excreted almost entirely in bile, is preferable to gentamicin, an antibiotic having satisfactory serum levels only. The patients were allocated to one of three groups: 50 received gentamicin (150 mg, i.m.), 50 received rifamide (80 mg, i.m.), and 50 controls received no antibiotic cover. The antibiotics were administered at the specified dose twice on the day of the operation, and every 8 hr for 5 days thereafter. Bile was aspirated from the gallbladder in 78 patients receiving antibiotics and from the bile duct through the cholangiogram catheter in 70 of these cases. The biliary and serum levels of antibiotics that were considered to be adequate for prophylactic therapy were 62 mg/l for rifamicin and 4 mg/l for gentamicin. Adequate serum gentamicin levels were present in 88% of 43 patients, but the levels in bile were extremely low; only two gallbladder samples and none of the collections from the bile duct exceeded 4 mg/l. None of the patients had adequate serum rifamide concentrations. When there was no biliary obstruction, however, rifamide bile levels were high (in many cases exceeding 1,000 mg/l). When the cystic duct was obstructed, the gallbladder levels of rifamicin were less than 5 mg/l, and adequate bile levels were achieved in only two jaundiced patients. Wound sepsis occurred in 22% of controls, in 10% of those receiving rifamide, and in only 6% of those receiving gentamicin ($p<0.05$, in comparison to controls). Gentamicin was also associated with a significant reduction of septicemia, from 14% to 2% compared with controls. These results suggest that adequate serum levels of an effective antimicrobial agent are more important in reducing the septic complications of biliary operations than an antibiotic that is excreted almost entirely into the bile.

5232 PERIAMPULLARY CANCER: A CLINICOPATHOLOGIC STUDY OF SIXTY-TWO PATIENTS. (Eng.)

Wise, L.; Pizzimbono, C.; Dehner, L. P. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Am. J. Surg.* 131(2):141-148; 1976.

Clinical experience with 62 patients with periampullary cancer, including carcinomas of the terminal common bile duct, terminal pancreatic duct, and the duodenum located near the ampulla of Vater is reviewed. Correct preoperative diagnosis was made in only 25% of the cases. Weight loss, anorexia, and obstructive jaundice were the most common clinical features. Associated diseases included chronic duodenal ulcer in five patients, diabetes mellitus in two, cirrhosis in one, and pernicious anemia in one. Eleven patients had had a cholecystectomy for cholelithiasis. Preoperative laboratory studies showed that almost half of the patients were anemic and more than 70% had guaiac-positive stools. Serum bilirubin levels were gradually increasing in 30 of 56 patients. At laparotomy, the tumor was palpable through the duodenal wall in 95% of the patients. The surgical treatment in this series included 47 curative and 15 palliative procedures. Biopsies for immediate frozen section examination were positive for carcinoma in 36/43 patients, intermediate in 3/43, and negative in 4/43. Operative mortality was about 14%. The authors conclude that: in patients with obstructive jaundice, the periampullary area should be carefully palpated even in the presence of stones in the common bile duct; the diagnosis of periampullary carcinoma versus carcinoma of the head of the pancreas is a macroscopic topographic rather than a histologic diagnosis; although node involvement decreases the 5-yr survival rate, it does not exclude it, therefore, nodal involvement is not a contraindication for radical resection; and in elderly, poor risk patients with small localized tumors, local resection may be an acceptable alternative to pancreatoduodenectomy.

5233 PRIMARY SCLEROSING CHOLANGITIS AND ULCERATIVE COLITIS. (Eng.) Morl, M.; Classen, M. (Stoffwechselklinik der LVA Wurttemberg, D-699 Bad Mergentheim, W. Germany). *Acta Hepatogastroenterol.* 22(6):415-419; 1975.

The case of a 36-yr-old man with a rare combination of ulcerative colitis and primary sclerosing cholangitis is reported. Disease of the biliary tract was suspected on the basis of the endoscopic retrograde examination of the common bile duct; there were massive pathological changes in the entire bile duct system, with considerable variation in the caliber of the common bile, cystic, and hepatic ducts. The filling of the gallbladder was inhomogeneous. The biliary tract disease was serologically differentiated from a chronic destructive, nonsupperative cholangitis because there were no antimitochondrial antibodies. A hepaticojejunostomy was carried out to normalize the bile flow.

5234 SPHINCTEROTOMY TREATMENT FOR BILIARY TRACT STONES. A RETROSPECTIVE REVIEW. (Eng.) Meyhoff, H. H. (St. Joseph's Hosp., Copenhagen, Denmark). *Acta Chir. Scand.* 141(7):645-648; 1975.

The cases of 106 patients with biliary tract stones, who underwent an operative procedure that included transduodenal sphincterotomy, are reviewed. The patients underwent supraduodenal choledochotomy with an attempt to carry out conventional sanitation of the biliary tract before the transduodenal sphincterotomy. The indication for sphincterotomy was mainly the presence of wedged papillary stones or multiple common duct stones. Fifty-two patients underwent i.v. cholangiography at least 2 yr postoperatively as a follow-up to surgery. Fifty-one patients had papillary stones removed via the sphincterotomy. Stones were missed in 8 of 102 patients, but were passed spontaneously in 2 patients during the observation period. Postoperative mortality was 10.4%, and four deaths were due to fatal pancreatitis. It is concluded that the procedure of sphincterotomy allows certain identification and removal of wedged papillary stones, but does not always allow that missed stones will be passed spontaneously.

5235 GALLBLADDER DISEASE IN THE YOUNG MALE. (Eng.) Haff, R. C.; Andrassy, R. J.; LeGrand, D. R.; Ratner, I. A. (U.S.A.F. Medical Center, Lackland Air Force Base, TX 78236). *Am. J. Surg.* 131(2):232-234; 1976.

The process of gallbladder disease in young men was assessed in 18 male patients, aged 6 months-20 yr, undergoing cholecystectomy. The medical history of these patients was obtained from a survey of 2,614 patients undergoing cholecystectomy at two large hospitals during a 5-yr period. The duration of preoperative symptoms ranged from 1 day to 3.5 yr. Five patients had acalculous cholecystitis; in three, this was associated with systemic sepsis, and in two, the acalculous cholecystitis was associated with biliary tract anomalies. Of the 13 patients with cholelithiasis, two had sickle cell disease and one had Gilbert's disease; the remaining patients had none of the predisposing factors to gallbladder disease in young males. None of the 12 patients having cholecystectomy alone had complications. Four of the six patients subjected to manipulation of the common bile duct in association with cholecystectomy had complications, but no fatalities occurred. Although gallbladder disease resulting in cholecystectomy in young males remains rare, the presence of abdominal pain, jaundice, or unexplained fever should lead to investigation of the biliary tract.

5236 BENIGN TUMORS AS THE CAUSE OF EXTRAHEPATIC OBSTRUCTION SYNDROME. REPORT ON A NEUROMA OF THE BILE DUCTS. (Ger.) Wiermann, H.; Wienbeck, M. (Endokrinologische Abteilung, Med. Universitats-Klinik, D-43 Essen, Hufelandstrasse, W. Germany). *Z. Gastroenterol.* 13(8):685-689; 1975.

A case of common bile duct neuroma in a 29-yr-old patient is described. Icterus had been present for two months. Duodenoscopy with choledochopancreatography showed disjuncture of the common bile duct above the junction with the cystic duct. An extrahepatic bile duct tumor was diagnosed by retrograde endoscopic cholangiography. Laparoscopy confirmed the diagnosis, and surgery was performed. Histological examination revealed neuroma with a marked increase in nerve fibers and formation of collateral fibrosis. Three months postoperatively, clinical examination and laboratory tests showed no evidence of pathological changes.

GENERAL

5287 SALINE LAVAGE: A RAPID, EFFECTIVE, AND ACCEPTABLE METHOD FOR CLEANSING THE GASTROINTESTINAL TRACT. (Eng.) Levy, A. G.; Benson, J. W.; Hewlett, E. L.; Herdt, J. R.; Doppman, J. L.; Gordon, R. S., Jr. (Natl. Inst. Arthritis, Metabolism, Digestive Diseases, Natl. Insts. Health, Bethesda, MD 20014). *Gastroenterology* 70(2):157-161; 1976.

The efficacy of saline lavage (without dietary restrictions or cleansing enemas) as a gentle, alternative method for cleansing the bowel in preparation for diagnostic studies was examined and compared to the standard castor oil method of bowel preparation. Lavage cleansing was preferred by 16 of 21 patients who had previously experienced a castor oil preparation; 2 patients expressed no preference, and 5 patients preferred castor oil preparation. Although 11% of patients could not consume an adequate (4-1) lavage volume, there was no significant difference in the preparation success rate between the remaining lavage patients and the castor oil patients. Total preparation time for lavage (3 ± 1 hr) was 60% less than for castor oil. The anticipated dehydration produced by castor oil and the hydration produced by lavage were confirmed. No significant changes were noted in serum electrolytes with either method of preparation. Additional early studies are promising for the lavage method when used in inflammatory bowel disease patients and as a cleansing preparation for colonoscopy.

5288 SOMATOSTATIN AND SERUM GASTRIN IN NORMAL SUBJECTS AND IN PATIENTS WITH PERNICIOUS ANAEMIA, CHRONIC LIVER AND RENAL DISEASE. (Eng.) Le Roith, D.; Vinik, A. I.; Epstein, S.; Baron, P.; Olkenitzky, M. N.; Pimstone, B. L. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 49(39):1601-1604; 1975.

The effects of somatostatin on basal gastrin levels were studied in 4 patients with pernicious anemia, in 6 patients with chronic renal disease, in 6 patients with liver disease, and during sequential arginine/insulin-stimulated gastrin release in 12 normal subjects. Basal gastrin concentrations were normal (10-50 pg/ml) in the controls, in the patients with liver disease, and in four of the patients with renal disease; somatostatin (200 µg, i.v., over 20 min) had no effect on gastrin levels in these patients. In the remaining patients, the basal gastrin levels were raised (152 pg/ml mean in patients with pernicious anemia), and the gastrin levels in these patients were significantly inhibited by somatostatin (mean, 78.5 pg/ml at 5 min after infusion in patients with pernicious anemia). The half-life of somatostatin in these patients was 3-4 min. Arginine infusion (10 mg/kg/min, 30 min) caused an insignificant increa in serum gastrin, whereas hypoglycemia induced by the injection of insulin (0.1 U/kg) significantly stimulated gastrin release. The increase in gastrin release caused by arginine infusion was not affected by somatostatin, but the increase caused

LIBRARY U. OF

by insulin was inhibited by somatostatin. The suppression of raised gastrin concentrations in the patients with pernicious anemia or chronic renal disease suggests that the hyperactive G cell is suppressible by somatostatin.

5289 SPONTANEOUS PERITONITIS OF CIRRHOSIS DUE TO CAMPYLOBACTER FETUS.

(Eng.) Targan, S. R.; Chow, A. W.; Guze, L. B. (Harbor General Hosp., 1000 W. Carson St., Torrance, CA 90509). *Gastroenterology* 71(2):311-313; 1976.

An unusual case of spontaneous peritonitis due to *Campylobacter fetus* infection in a patient with cirrhosis is reported. The patient, a 59-yr-old man with a history of alcohol abuse, presented with diarrhea, anorexia, vomiting, dull abdominal pain, and increasing abdominal girth. Paracentesis revealed hazy, clotted fluid. Empiric antimicrobial therapy was begun with gentamicin and clindamycin (80 and 600 mg, resp., i.v. every 8 hr). Although blood and urine cultures were sterile, the peritoneal fluid grew a microaerophilic, gram-negative, curved bacillus with a unipolar single flagellum, subsequently identified as the *C. fetus* subspecies, *intestinalis*. The antibiotic therapy was discontinued on the 10th hospital day, and the patient died on the 15th day; the autopsy revealed advanced Laennec's cirrhosis, secondary hemochromatosis, and chronic prostatitis. *C. fetus* has been increasingly associated with cirrhosis and other human diseases, but this is apparently the first report of it being associated with spontaneous peritonitis. The infection is characteristically relapsing in nature and requires protracted antimicrobial therapy.

5290 UNFAVORABLE EFFECT OF ATROPINE-DIPHENOXYLATE (LOMOTIL) THERAPY IN LINCOMYCIN-CAUSED DIARRHEA.

(Eng.) Novak, E.; Lee, J. G.; Seckman, C. E.; Phillips, J. P.; DiSanto, A. R. (Upjohn Co., 7000 Portage Rd., Kalamazoo, MI 49001). *JAMA* 235(14):1451-1454; 1976.

In a double-blind, randomized study, the effect of atropine-diphenoxylate (Lomotil) therapy on lincomycin-induced diarrhea was studied in 200 normal men. The subjects received one of the following treatment combinations: (1) lincomycin (600 mg) and two placebo tablets, (2) lincomycin and two tablets of an atropine-diphenoxylate mixture, (3) lincomycin and two tablets of an aspirin-phenacetin-caffeine (APC) mixture with codeine phosphate (APCC, 0.06 g), (4) lincomycin and two tablets of APC mixture, or (5) saline (2 ml) and two placebo tablets. Each subject received four i.m. injections of lincomycin or saline and four p.o. doses of one of the treatment combinations daily for 3 days. The group receiving lincomycin with atropine-diphenoxylate (11/40) and the group receiving lincomycin with APCC (14/36) had a higher incidence of diarrhea from day 4 through day 6, followed by the groups receiving lincomycin with APC mixture (9/39), lincomycin with placebo (8/39), and saline with placebo (1/38). The difference was statistically significant ($p<0.05$) on days 3, 4, and 5. From day 4, the mean daily total and loose stool counts for the group receiving lincomycin with atropine-diphenoxylate were about twice that of the mean of the groups receiving placebo ($p<0.05$). The group receiving lincomycin with placebo had the lowest incidence (0/37) and the group receiving lincomycin with APCC had the highest incidence (7/34) of nausea and loss of appetite (10/36) among all the treatment groups. Decreased intestinal motility from atropine-diphenoxylate or codeine may increase the contact time between the lincomycin (or its metabolites) or some developing toxic substances and the mucosal epithelium. The use of atropine-diphenoxylate or codeine in treating lincomycin-induced diarrhea is questionable.

5291 ANTIDIARRHEAL AGENTS IN THE TREATMENT OF ACUTE DIARRHEA IN CHILDREN.

(Eng.) Portnoy, B. L.; DuPont, H. L.; Pruitt, D.; Abdo, J. A.; Rodriguez, J. T. (Univ. Texas Medical Sch., P.O. Box 20708, Houston, TX 77030). *JAMA* 236(7):844-846; 1976.

The efficacy of antidiarrheal agents was evaluated in 80 children (aged 3-11 yr) with acute diarrheal illness. The children were hospitalized after experiencing an average of 3.5 days of diarrhea, and were treated for 2 days with one of five agents (16 patients each): kaolin-pectin suspension concentrate, kaolin suspension, pectin suspension, diphenoxylate-atropine liquid, or placebo. Although the patients receiving kaolin-pectin produced stools that tended to be more formed than those of the placebo-treated group patients, the study did not demonstrate any effect by any of the agents in influencing the frequency of bowel movement, the water content of the stools, or the weight of stools. The kaolin-pectin suspension and diphenoxylate-atropine liquid do not appear to be useful in the relief of acute nonspecific diarrhea in children.

5292 FECAL STEROIDS IN DIARRHEA. I. ACUTE SHIGELLOSIS.

(Eng.) Huang, C. T. L.; Woodward, W. E.; Hornick, R. B.; Rodriguez, J. T.; Nichols, B. L. (Baylor Coll. Medicine, Houston, TX). *Am. J. Clin. Nutr.* 29(9):949-955; 1976.

The hypothesis that altered bile acid metabolism may play a role in the association between acute diarrheal episodes and malnutrition was tested. Fecal bile acid and neutral sterol patterns of five healthy men, who were challenged by a virulent *Shigella flexneri* 2a (M42 43) strain and developed dysentery, were studied. Cholic acid was increased from 1.9 ± 0.4% of total bile acid in the feces before infection to 14.5 ± 2.1% during diarrhea ($p<0.001$). Chenodeoxycholic acid also was increased from 3.2 ± 0.7 to 8.7 ± 3.2% in diarrhea, but the difference was not statistically significant. Deoxycholic and lithocholic acids constituted 34.1 ± 4.1 and 40.5 ± 2.8%, resp., of total bile acid in the subjects before the induction of diarrhea, compared to 13.9 ± 2.5 and 24.8 ± 2.5% for the same subjects during diarrhea ($p<0.005$). The total excretion of bile acids was higher in diarrhea than that in controls, but the difference was not statistically significant. In the neutral sterol fraction, unmodified cholesterol was increased during diarrhea (86.2 ± 8.7 versus 25.0 ± 4.8% of total cholesterol metabolites in controls, $p<0.001$). Coprostanol was decreased in shigellosis (12.2 ± 8.2 versus 65.8 ± 4.7% in controls, $p<0.001$). Epicoprostanol, coprostanone, and unidentified cholesterol metabolites also were reduced in shigellosis. The effect of diarrhea on the plant sterols was not as consistent; however, unidentified plant sterols were reduced significantly in shigellosis stools. Total excretion of cholesterol metabolites and plant sterols was 6.8 ± 1.7 and 0.6 ± 0.2 mg/kg/day, resp., in shigellosis, which was not significantly different from the corresponding values for controls. One subject's stool samples were studied during infection for the sequence of bile acid alteration. A progressive reduction of bacterial activity upon fecal steroids was evident following the initial diarrheal episode. The production of coprostanol was correlated with 7α-dehydroxylation of cholic acid ($r=0.937$, $p<0.001$) and chenodeoxycholic acid ($r=0.755$, $p<0.01$). The lack of effect of shigellosis on total fecal sterol excretions differs from previous observations. The available information suggests that several mechanisms are able to alter the bacterial degradation of intestinal steroids.

5293 DIFFUSE EOSINOPHILIC GASTROENTERITIS ASSOCIATED WITH PSEUDOPOLYPS. (Ger.) Fehr, H. F. (Medizinische Klinik, Kantonsspital, CH-5001 Aarau, Switzerland). *Z. Gastroenterol.* 8(5):534; 1975.

A case of eosinophilic gastroenteritis associated with pseudopolyps and with pathological changes in the fundus and corpus of the stomach is described. Clinically extreme emaciation was present. Laboratory tests showed decreased total protein (5.3 g%) and slight eosinophilia (4.5-6.5%). The pentagastrin test revealed complete anacidity and an hourly secretion of 58 cm^3; radiologically inelastic stomach wall, filling defects, and suspicious ulcer formation in the fundus and corpus were present. Endoscopy revealed bleeding, ulcerative tumor-like polyps in the fundus and corpus, with only a few tiny polyps in the antrum and duodenum, and atrophic mucosa. Biopsy revealed inflammatory histiocyte polyps with diffuse eosinophilic infiltration. The symptoms ceased at first without therapy; their recurrence 1 month later was treated successfully with corticosteroids.

5294 DOES HYPERPARATHYROIDISM CAUSE HYPERGASTRINEMIA? (Eng.) Wilson, S. D.; Singh, R. B.; Kalkhoff, R. K.; Go, V. L. W. (Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI 53226). *Surgery* 80(2):231-237; 1976.

To define the relationship between hyperparathyroidism (HPT) and gastric function, 31 patients with HPT were studied before and 2-25 months after parathyroidectomy. The gastrin response to a standard test meal (STM), the basal acid output (BAO), and the peak acid output (PAO) were determined. Parathormone and calcium were elevated (mean=11.3 mg% for calcium and 85 µl Eq/m for parathormone) in all patients and returned to normal (9.3 mg% and 28 µl Eq/m, resp.) following parathyroidectomy. The mean fasting gastrin concentration (195 pg/ml), mean integrated gastrin response (IGR) to feeding (9.9 ng/ml x 60 min), mean BAO (3.6 mEq), and mean PAO (24.1 mEq) were not changed significantly by parathyroidectomy. There wa no significant correlation between gastrin concentration or gastrin response to feeding and gastric acid secretion. Eight of 31 HPT patients had fasting gastrin concentrations above normal preoperatively, which remained so postoperatively. Hypergastrinemia in six of these eight patients was explained by the Zollinger-Ellison syndrome or chronic atrophic gastritis. The hypothesis that peptic ulcer disease seen in some HPT patients is the result of calcium-induced hypergastrinemia causing gastric hypersecretion is not supported by these results.

5295 ACUTE GASTRODUODENAL LESIONS RELATED TO SEVERE SEPSIS. (Eng.) Le Gall, J. R.; Mignon, F. C.; Rapin, M.; Redjemi, M.; Harari, A.; Bader, J. P.; Soussy, C. J. (Henri Mondor Hosp., Creteil, France). *Surg. Gynecol. Obstet.* 142(3):377-380; 1976.

The incidence and role of sepsis in acute gastrointestinal lesions were studied in 30 patients. Nineteen fibroscopies were performed in 14 patients with sepsis, and 23 fibroscopies were performed in the 16 patients without sepsis. Lesions of the gastroduodenal mucosa were classed into five increasing stages: stage 0, normal; stage I, extensive erythematous, purpuric, macular lesions; stage II, discrete and superficial erosions; stage III, one or several gastric or duodenal ulcers without bleeding; and stage IV, one or several bleeding ulcers. Six of the 19 fibroscopies performed in the patients with sepsis showed stage I or II lesions, and 13 showed stage III or IV lesions. In the first day of septicemia, all lesions were in stage I or II. From the fourth day on, the lesions were in stage III or IV, and by the sixth day of septicemia, the lesions were in stage IV in all patients. Of the 23 fibroscopies in the patients without sepsis, 12 showed a normal mucosa, and 11 showed stage I or II lesions. The differences in the incidence and severity of gastroduodenal disease between the two groups were highly significant ($p<0.001$). The incidence of acute gastroduodenal lesions in all 30 patients could not be correlated with an earlier episode of shock, respiratory failure, renal failure, or the presence of gastric biliary reflux. The data suggest that severe sepsis *per se* can provoke acute damage to the mucosa of the stomach.

5296 PRINCIPLES OF CORRECTION OF SOME HOMEOSTATIC DISTURBANCES IN ACUTE INTESTINAL INFECTION IN CHILDREN, AGED UNDER ONE YEAR. (Rus.) Bondareva, N. V.; Malkovetz, G. I. (Belorussian Inst. Postgraduate Training Physicians, Minsk, USSR). *Vopr. Okhr. Materin. Det.* 20(9):12-16; 1975.

GENERAL

Regional Enteritis

5352 BACTERIAL VARIANTS: ETIOLOGIC AGENT IN CROHN'S DISEASE? (Eng.) Parent, K.; Mitchell, P. D. (Marshfield Clinic, Marshfield, WI 54449). *Gastroenterology* 71(2):365-368; 1976.

The hypothesis that the infectious agent in Crohn's disease may be a bacteriophage-induced L-form or similar variant was tested by culturing operative colonic and small bowel specimens from seven patients, and examining them for L-phase growth by dark field microscopy. Bacterial variants of *Pseudomonas maltophilia* and *Pseudomonas*-like bacteria were recovered from tissues from three successive patients with Crohn's disease and from one patient with clinical and pathological features of both Crohn's disease and chronic ulcerative colitis. Bacterial variants were not cultured from colonic specimens of one patient with classical features of chronic ulcerative colitis and two patients with adenocarcinoma of the colon. The findings suggest that a relation exists between variant bacteria and the pathogenesis of Crohn's disease.

5353 INDICATIONS FOR SURGERY IN CROHN'S DISEASE: ANALYSIS OF 500 CASES. (Eng.) Farmer, R. G.; Hawk, W. A.; Turnbull, R. B., Jr. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Gastroenterology* 71(2):245-250; 1976.

To determine whether the anatomic area of involvement in Crohn's disease is a major determinant in prognosis, data from 500 patients with Crohn's disease who underwent surgery were analyzed. The primary disease locations were: ileocolic, 225 patients; small intestinal, 130 patients; colonic, 127 patients; and anorectal, 18 patients. Indications for surgery were tabulated and compared using statistical analysis. For patients with ileocolic Crohn's disease, the primary surgical indications were internal fistula and abscess, 44%; intestinal obstruction, 35%; and perianal disease, 12%. For patients with Crohn's disease of the small intestine, the primary surgical indications were intestinal obstruction, 55%, and intestinal fistula and abscess, 32%. Patients with colonic Crohn's disease had a significantly more diverse surgical indication, with poor response to medical therapy, 26%; internal fistula and abscess, 23%; toxic megacolon, 20%; and perianal disease, 19%. This study demonstrates that statistically significant differences occur in the surgical indication depending on the location of Crohn's disease. Patients with ileocolic, small intestinal, and colonic involvement have striking differences in clinical course. It is concluded that Crohn's disease is not a homogeneous entity, but should be recognized as having a varying course depending on the clinical pattern.

5354 ELECTRON MICROSCOPIC STUDIES OF VIRAL AGENTS IN CROHN'S DISEASE. (Eng.) Gitnick, G. L.; Rosen, V. J. (U.C.L.A., Center Health Sciences, Los Angeles, CA 90024). *Lancet* 2(7979):217-219; 1976.

Ileal filtrates of patients with Crohn's disease were cultivated in a new tissue culture cell line, continuous rabbit ileum (CRI). CRI cultures were inoculated with filtrates prepared from the ilea of four patients with Crohn's disease and from four patients with normal small intestine. Tissue-culture grown isolates from patients with Crohn's disease were also inoculated. Electron microscopic studies revealed extensive disintegration of ultrastructure and significant membrane abnormalities. Clusters of viral particles were seen in the cultures inoculated with the tissue-culture grown isolates. The particles consisted of a membrane and an electron-opaque core, and their coats were spiculated. The mean particle diameter was 30 nm. No intranuclear particles were seen. The physical chemical properties of this agent, together with its electron microscopic appearance, indicate that this is a picornavirus.

LIBRARY U. OF

5355 MAST CELLS AND IMMUNOGLOBULIN E IN INFLAMMATORY BOWEL DISEASE. (Eng.) Lloyd, G.; Green, F. H. Y.; Fox, H.; Mani, V.; Turnberg, L. A. (Microbiological Res. Establishment, Porton, Wiltshire, England). *Gut* 16(11):861-865; 1975.

The numbers of mast cells and immunoglobulin E (IgE)-containing immunocytes in the bowel wall of patients with Crohn's disease or ulcerative colitis were estimated, and the results were compared with those from normal controls. Mast cells were studied in fresh, surgically resected or biopsy specimens. IgE was demonstrated by an indirect immunofluorescence technique using commercially-prepared, unconjugated rabbit monospecific anti-human IgE. Mast cells were easily identified in the submucosa of all specimens by their size, cytoplasmic granularity, and metachromasia. They tended to be localized near the muscularis mucosa. There was a statistically significant ($p<0.001$) decrease in the number of mast cells in both the lamina propria and the submucosa in the ileum of patients with Crohn's disease compared to controls. There were also significant decreases in mast cells in the colon and rectum of patients with Crohn's disease. In patients with ulcerative colitis, there was a moderately significant ($p<0.05$) increase in the mast cell population in the lamina propria and submucosa of both the colon and the rectum. In areas of the bowel involved by Crohn's disease, the ratio of mast cells to total leukocytes declined markedly, while in lesions due to ulcerative colitis, the proportion of the leukocyte population accounted for by mast cells was not significantly altered. In Crohn's disease, there was a marked fall in the absolute number of IgE-containing immunocytes in the ileal, colon, and rectum specimens. There was only a slight decline in IgE-containing immunocytes in colons and rectums affected by ulcerative colitis. The results indicate that there are significant differences between ulcerative colitis and Crohn's disease in respect to the mucosal populations of mast cells and Ig-containing immunocytes.

5356 THE SUBPOPULATIONS OF CIRCULATING WHITE BLOOD CELLS IN INFLAMMATORY BOWEL DISEASE. (Eng.) Thayer, W. R., Jr.; Charland, C.; Field, C. E. (Rhode Island Hosp., Providence, RI). *Gastroenterology* 71(3):379-384; 1976.

To determine whether there is a decrease in the number of circulating thymus-derived (T) cells in inflammatory bowel disease (IBD), a detailed analysis of the lymphocyte species was carried out in 31 patients with Crohn's disease (CD) and 27 patients with ulcerative colitis (UC). There were 13 CD patients with only small bowel involvement called regional enteritis, and 18 who had some degree of colonic involvement, called ileocolitis. Similarly, the UC group was subdivided into 9 patients with disease confined to the rectosigmoid area, called proctosigmoiditis, and 18 with more extensive involvement, called universal colitis. Thirteen patients who had undergone previous colectomy and ileostomy and 78 healthy age- and sex-matched controls were also studied. Although there was no increase in the absolute number of lymphocytes in patients with ileocolitis and universal colitis, the percentage of lymphocytes was decreased because of an increase in both polymorphonuclear leukocytes and monocytes. In IBD and its subgroups, the mean T lymphocytes, determined by the sheep RBC rosette technique, were not significantly different from the controls either in percentage or absolute number. Furthermore, no difference was noted between UC and CD. There seemed to be a subpopulation of patients with UC or CD whose T cells were reduced below 1 standard deviation of the mean, however. No difference in the number of immunoglobulin-bearing bone marrow-derived (B) cells was seen; however, when the B cells were enumerated by their ability to rosette with antibody-complement-coated RBC, a marked decrease in percentage ($p<0.001$) and absolute number ($p<0.0005$) of B cells was found relative to the control population. The decrease bore a direct relation to the severity of the disease process and, although more marked in patients with UC, was also present in CD.

5357 GASTRODUODENAL CROHN DISEASE. (Eng.) Tootla, F.; Lucas, R. J.; Bernacki, E. G.; Tabor, H. (William Beaumont Hosp., 3601 W. 13 Mile Rd., Royal Oak, MI 48072). *Arch. Surg.* 111(8):855-857; 1976.

Experience with three young women (aged 18-24 yr) with upper gastrointestinal tract symptoms associated with Crohn's disease is described. All three patients required operation for relief of symptoms. Two operations were performed for gastric outlet obstruction, and one for massive hemorrhage. All patients had roentgenographic or gastroscopic evidence suggestive of Crohn's disease, and in each, the diagnosis was confirmed histopathologically. The operative procedures consisted of distal gastrectomy in two cases and gastrojejunostomy in the third. All three patients have or have had evidence of Crohn s disease of the small intestine, and none of them responded to medical management. In the most recent case, medical management included i.v. hyperalimentation. Experience with these cases suggests that symptomatic involvement of the stomach in Crohn's disease will not respond to medical treatment and will require surgical measures for relief.

5358 URETERIC OBSTRUCTION COMPLICATING CROHN'S DISEASE IN THE TERMINAL ILEUM. (Eng.) Fasth, S.; Filipsson, S.; Hulten, L.; Lindhagen, J. (Sahlgrenska sjukhuset, Univ. Goteborg, Goteborg, Sweden). *Acta Chir. Scand.* 142(3):275-277; 1976.

Three cases of obstructive hydronephrosis secondary to Crohn's disease in the terminal ileum are presented. The first patient, a 52-yr-old man, was found at laparotomy to have a mass involving the terminal ileum and its mesentery and extending into the retroperitoneal tissue; the right ureter was adherent to this mass. The patient made an uneventful recovery after the ureter was dissected free, the diseased intestine was resected, and an end-to-end ileoascendostomy was made. The second patient, a 27-yr-old woman, had a prestomal recurrence of Crohn's disease 4 yr after proctocolectomy and ileostomy. An advanced transmural intestinal inflammatory reaction was found in the distal 50 cm of ileum, and the inflammatory process extended into the mesentery and the paraintestinal and right retroperitoneal space, where a cicatrical fibrous tissue mass had formed. The right ureter had been severed where it passed through the mass. An end-to-end anastomosis was performed between the two ureteral ends; nephrectomy was subsequently performed because of local infection and pyonephrosis. In the third patient, a 27-yr-old woman, excretory pyelography showed an extrinsic obstruction of the right ureter at the level of the pelvic brim, associated with a considerable hydroureter and hydronephrosis. The excretion was considerably delayed on the right side. At laparotomy an inflammatory mass involving the ileum, cecum, ureter, right ovary, and fallopian tube was observed. The ureter was successfully dissected free, and subtotal colectomy, resection of the ileum, and an end-to-end ileosigmoid anastomosis were performed. Urinary tract symptoms were absent in all patients. The third case illustrates the importance of a preoperative i.v. urogram; this procedure in the second patient may have lessened the risk of ureteral damage by laying the basis for a more careful technical approach.

LIBRARY U. C.

5359 MULTIPLE SUPERFICIAL GASTRIC EROSIONS DUE TO CROHN'S DISEASE OF THE STOMACH. RADIOLOGIC AND ENDOSCOPIC DIAGNOSIS. (Eng.) Laufer, I.; Trueman, T.; deSa, D. (McMaster Univ. Medical Center, Hamilton, Ontario, Canada L8S 4J9). *Br. J. Radiol.* 49(584):726-728; 1976.

The case of a 21-yr-old man with Crohn's disease involving the stomach and duodenum is presented. The patient had a 4.5-yr history of ankylosing spondylitis. Double contrast radiography of the stomach and duodenum showed multiple superficial gastric erosions and a duodenal ulcer. Changes typical of Crohn's disease were seen in the terminal ileum. Endoscopy revealed numerous superficial erosions in the stomach and duodenum, and biopsies of the stomach showed granulomatous inflammation, consistent with Crohn's disease. These lesions were similar to those seen in the colon in the early stages of granulomatous colitis, and it is likely that this represents the early stage of Crohn's disease in the stomach. With increasing application of double-contrast radiography and endoscopy, these lesions may be found more frequently.
